7446. But supposing that the water was always available, and when once it was sent it was not allowed to run dry? Then you might be able to do it.

Tanks. 7447. What means would you propose to water the country lying between the Darling and the Lachlan? The only means is by excavating tanks.

7448. Are there no other means? None at all.

7449. Then you do not think that any improvement could be made on the present means of watering the country? No.

Diversion from the Darling. 7450. Not by diverting a portion of the Darling? No; because the back country is so much higher than the Darling.

7451. Are you aware that the Darling and the Lachlan water came within 30 miles of each other in the flood of 1870, opposite the Willandra Billabong? It might have done so there. I know nothing of the country down by the Willandra Billabong.

7452. How far down do you know the Darling? To Wilcannia.

7453. And do you think the water from the Darling might be taken out towards the Willandra Billabong from or near Wilcannia? I should not like to answer that question, because I do not know much about the country between Wilcannia and the Willandra.

7454. But supposing that the country is not too high, do you think it possible to divert a portion of the Darling water towards the Lachlan? From what I know of the country I do not believe it is.

7455. Why, if the country is not too high? From what I know of the country I do not believe it is possible. I may mention that out on the left bank of the Darling coming round, I have heard that water has been got out from the south-east of the river a distance of between 20 and 30 miles.

7456. Supposing that the country is not too high, is there any other reason why the Darling water could not be taken through that country? But the country is too high.

7457. But if the flood-water of 1870 came out near to the Willandra, that proves that the country is not too high? If it did so.

7458. But we have evidence that it did? I do not know anything about that country at all.

7459. But is there no other reason you know of except the elevation that would prevent the water from being taken? If it were all flat country between the Darling and the Lachlan the water might then be diverted.

7460. But there is no other obstacle except the elevation of the country? If the country between the Darling and the Willandra were all flat country, and the water of the Darling were raised a sufficient height, it could be diverted into the Willandra Billabong.

7461. There are no natural features of the country which would prevent the water from being diverted? Whoever gave evidence about the waters meeting may have been right, but I think he must have been wrong, because I know all the country about Woore and Booroondarra to be hilly country—mallee ranges.

7462. But what I want to know is whether—if the elevation is not too great to prevent the water from being diverted—there is anything in the soil or the surface of the country that would prevent it; is it sufficiently good holding ground? It is of a red, porous nature. It would hold water in a canal, but it would be impossible to make a canal through that country to carry the water back from the Darling.

Holding ground.

Mr. G. C. Tompson. 27 May, 1885.

7463. But supposing that it is possible, would a canal hold and carry water? Yes.
7464. Do you think the evaporation in the canal would be too great to carry the water any distance? I do.
7465. In the paper you read you gave a list with the values of the runs in this district at the time they were taken up, and down to the present time? Yes.
7466. You gave the value of runs in 1880, and you mention that one run was sold for £10,000: what is the value of that run now—has it increased in value? That is not my valuation; it is what the run brought. Value of runs.
7467. But has it increased in value since? No.
7468. Why? Because the value in 1880 was a fictitious one altogether. I mentioned that because in 1874 several runs were forfeited because £20 rent was put upon them, and in the same year two runs changed hands for £45. In the year 1876, when the drought was in the inner districts, the sheep were forced from the inner districts out through this country for grass. At that time, the winter of 1876, the country was looking magnificent, and the sheep after three months, were taken back fat. Afterwards the blocks ran up to £300, £500, £1,000, and upwards. Before the runs were stocked the people on the frontages said that catches for water could never be got on the back blocks, but when the country was stocked it was found after the first rain that the ground became hard in consequence of the tramping of the stock, and that there were watersheds to be availed of as the country was undulating.
7469. And in 1880 you knew one block to bring £10,000? Yes; I knew one block that was forfeited in 1874, because a rent of £20 was put on it, to bring £32,000 when stocked, in 1880.
7470. And you knew a naked block to bring £10,000 without any improvements? Yes.
7471. Is that block worth £10,000 now? I have not seen it for the last two years and more.
7472. Was it worth £10,000 in 1880? It was not.
7473. And still it brought it? Yes.
7474. Why was it not worth £10,000? That is my opinion.
7475. And if artificial water has been made upon it at various points, do you not think it is worth £10,000 now? I would not give it.
7476. What is the size of the block? 100 square miles.
7477. You have shown that the country has increased in a marvellous manner during ten years: do you think that increase will go on as artificial water is made? Nearly the whole of the country is improved now by the conservation of water in tanks. Improvements.
7478. But supposing that it is still further improved, do you think the value will go on increasing in the same proportion? No, I do not think the value will go on increasing. Value.
7479. Then if a man gives £10,000 for a block of country that will not carry stock at all, and he conserves water so as to make it capable of carrying 10,000 sheep, you think it is not worth as much as when he bought it? I am not considering that block at all, because it was not worth the money paid for it.
7480. But the value of a block is what it will bring in the open market? I do not know about that; but that block was bought privately.
7481. At any rate, in the opinion of the man who bought it, it was worth £10,000? He might have thought so at the time—he has been sorry for it since.
7482. He is on the country still? He is on the adjoining country.
7483. Then you think the Cobar country you refer to in your paper will not increase in value even if artificial water is made? I say that it is improved by artificial water now up to its full capacity. During the last three years the runholders have never been short of water, but they have been short of grass. At one time it was thought that in the Cobar country you could never conserve sufficient water for the stock until they ate off the grass, but the squatters now find that they have more water than will enable them to feed off the country. Cobar country.
7484. How near are the tanks to each other? It all depends. There might be a large tank at the corner of four paddocks. That would be an average of about 5 miles. Tanks.
7485. And do you think that one large tank will keep as much stock as three or four tanks distributed over the paddocks? No, because the sheep going to water at one tank cut up the grass more. If you have several tanks on a station the sheep do not do so much injury to the grass. Number of tanks.
7486. Then if there were two tanks where there is now one the run would carry more stock? It might carry more stock; but, as I mentioned before, the back country is already well improved by the conservation of water. On a block of 100 square miles you could certainly carry more stock with four tanks than if you only had one large one.
7487. But I will put the same question with respect to 20,000 acres? On 20,000 acres a tank in the centre would be ample without any other tanks, provided the block were square.
7488. That does away altogether with the value of small paddocks and plenty of water? If you had a tank in the centre of a 20,000-acre block, the sheep would not have more than 2 miles to travel.
7489. But supposing they had not half a mile to travel, do you think then that more stock could be carried? No, I do not think any more stock could be carried on the back country; on the frontage there might.
7490. What effect has water distributed from rivers, tanks, or dams on this grass in the back country—does it affect it as it does elsewhere—does plenty of water make plenty of grass? Of course; but I have mentioned that formerly in that part of the country, owing to the loose nature of the soil, if we had 50 points of rain it used to go into the roots of the grass; whereas now, owing to the hard crust formed on the surface by the tramping of the stock, the water runs into flats or tanks. Grass and water.
7491. If you irrigated any portion of that country would the effect be beneficial? It would. Irrigation.
7492. Would it produce fair crops? It would—very good crops indeed.
7493. Then if there was plenty of water and means of irrigating in the back country you think good crops would be grown? Yes.
7494. And would it improve the grass lands? Yes, irrigation would improve the grass.
7495. Then if there was an unlimited supply of water throughout that country, do you think the persons in the neighbourhood would avail themselves of it, if they could get the water on to the soil? Yes.
7496. Is there much country alienated in that direction? Very little, except around the mines. Alienated land.
7497. If there was plenty of water there, would the country carry a fairly large population? Yes, a very large population. Population.
7498. It is very good wheat-growing country, is it not? Yes; want of water is the only drawback; the land would grow wheat if a sufficient quantity of water could be obtained during the year. Wheat.

7499.

Mr. G. C. Tompson. 27 May, 1885.

7499. During what part of the year is rain necessary for wheat-growing? The crops ought to be in in March, and then if we had rain during March, April, and the winter months the crops would be ripe for cutting about November.

Seasons. 7500. As the seasons are at present you do not consider the rain sufficient for wheat-growing? It is not.

Irrigation. 7501. Do you think that if the station-holders had sufficient rain to grow crops they would grow any quantity for storage? If they had water they would.

Area. 7502. Do you know of instances where irrigation has been resorted to even on a small scale in that country? Yes; on Anyon's selection, on the road from Cobar to Louth, about 20 miles from Cobar.

Water. 7503. What size is the selection? 40 or 80 acres. Water is obtained from a little shaft which the selector has put down.

Soil. 7504. Was there plenty of water? No; there was a sufficient supply for a few human beings and one or two horses; a portion of ground had been cultivated and had a crop of wheat upon it.

Result. 7505. Was the soil red soil? Yes. About three years ago the selector showed me his crop, which he said was a failure. He had a dam on the upper side of the crop; he made a drain through his dam and conducted the water to the cultivated land, and the crop sprang up splendidly after the ground had been once or twice irrigated.

7506. And you consider that that instance clearly demonstrates the possibility of growing wheat if only plenty of water can be obtained? I do. I may mention another instance. The whole of the Cobar country was very bare, and people there said that nothing would ever grow. An old man named M'Guinness, on the other side of Cobar, fenced in a tank to keep the squatter's sheep from it. After a shower of rain the overflow from the tank passed over his enclosed land, and I saw grass there over 9 inches high. That was a proof that with sufficient water grass would grow on the country.

7507. At the time you saw the grass was the surrounding country bare? Yes, every bit of it.

Garden Irrigation. 7508. Do you know of any other places where irrigation has been resorted to? Not except for gardens.

Water supply. 7509. State generally what you know? The gardens in the back country are all kept up by irrigation.

Result. 7510. Is the water obtained from dams or from wells? All from dams or tanks.

Soil. 7511. Are they successful? Very successful. The red country will grow anything far better than the black soil.

7512. Is there a very large area between the Lachlan and the Darling? A very large area indeed. The red country, I may mention, is of a less saline nature than the black soil—it is that which causes it to be so good.

7513. *Mr. Targett.*] Does the red soil extend right to the river banks? In very few places—there are very few places where you can trace the red soil out to the Darling. At Gundabooka Station there is a high red bank, and the lessee thought he could carry the water out back by means of pipes for the stock. He employed a surveyor to take the levels, but they found before they got out 15 miles that they were 200 feet above the bank of the river.

7514. *President.*] Was the point at which the lessee attempted to take the water out at right angles to the Darling? Yes.

Floods on the Bogan. 7515. Can you give us any particulars of the flood of 1879? Yes. In 1879 all the red Budda sand ridges out from the Duck Creek were under water. The Bogan at this time was of very great width—in some places I should think it was 4 or 5 miles wide. I may mention that the best water-hole in the Bogan is at Golgolgon. There is an overshot dam at the lower end of Charlton Run on a bar of rocks; it is upwards of a mile in length, and deep; it is a natural bar of rocks across the river, about 50 miles above the junction with the Darling, up the Bogan.

7516. Is the country very flat above that bar of rocks? On the east side it is flat country, but on the west side it is ridgy country.

Storage water-holes. 7517. What I want to know is, whether if a dam were thrown across that bar of rocks there are any natural basins above where large quantities of water could be stored? There are water-holes, but it would not be advisable to put anything across that bar of rocks; it would be better to put a dam up higher, and that would be the means of conserving a large body of water.

7518. But why not raise the bar of rocks? Because you would flood all the low-lying land on the east side.

Natural basins. 7519. Are there no dry creeks, ana-branches, or natural basins where large quantities of water could be stored? You would have to confine the water to the channel of the Bogan. There are several creeks to the east of the river. If you raised a dam on the rocky bar you could send the water on the eastern side into Broomi Creek. The lessee of the Charlton Run did not bother about the Bogan River, but he put dams in the Broomi Creek, which runs parallel with the river.

Creeks.

Broomi Creek.

Dam. 7520. But if a dam were raised to any height on the reef of rocks you speak of, would any quantity of water be conserved by it? Yes, if you raised it to a certain height; but it would not be advisable to do it, because the money could be spent to greater advantage by going higher up.

7521. But you have said that if a dam were put on that bar it would store a large quantity of water? Yes; but if you put a dam there do not make it higher than the river, because the moment the water rises over the bank it will flood the country to the east. It would be advisable to put overshot dams in the Bogan above Gilgoonoo.

7522. But that would only be to conserve water in the bed of the river? That is all.

Basins. 7523. There are no natural basins? There are one or two; but all the country to the east is low-lying country, and you could only really conserve water in the bed of the Bogan River.

Silt. 7524. *Mr. Gipps.*] Is there much silt in the Bogan River in times of flood? Yes, I should think there was a great deal.

7525. *President.*] Has any silting ever taken place at that bed of rocks you spoke of? I do not think so. I may mention that there is a Chinaman's garden on the Gongolgin waterhole, where the finest crops are grown that I have ever seen. I may mention also, with regard to the overshot dam at the lower boundary of Charlton Run, that it throws the water back 5 miles, or rather it did; I have not seen the dam now for years.

Overshot dam.

Distribution. 7526. With reference to the country you were speaking of before, it is simply a question of levels as to whether or not water can be distributed over that country, and if it can be distributed it will make the soil very prolific? But I say that it is impossible to distribute it.

7527. But it is only a question of levels? Yes. If there was sufficient water on the country to irrigate it the country would become most valuable for agriculture. At Winbar, I should like to mention, when the Darling rises to a sufficient height it runs into a warrambool which goes out 5 miles from the river.

The Darling

Mr. G. C. Tompson.

27 May, 1885.

7528. Is there a bar across the river below the take-off? Not that I know of.
7529. And that warrambool is dammed—with what result? That a large body of water is conserved.
7530. Are there any other large dams or warrambools you wish to give the Commission any information about? No, not any others. You were talking about a sort of dividing range—I believe there is a dividing range running along by Nymagee. The fall seems to be towards the Darling below Wilcannia, and the fall from the ranges on the east side of Nymagee runs into the Darling below Bourke. Dividing Range.
7531. Then both fall towards the Darling? Yes. I consider that range of rocks at Nymagee is a dividing range. Fall.
7532. One watershed running into the Darling at Wilcannia, and the other below Bourke? Yes.
7533. Do you know if the supply of water in the Yantarra and Cobham Lakes is permanent? It is not. Yantarra and Cobham Lakes.
7534. Do you know of any means by which it could be made permanent? I do not.
7535. Not from the overflow of any rivers? No. About 10 chains from the Queensland border, on the Onepar blocks, there is a magnificent water-hole in what is known as Wampah. It is in the county of Tongowoko, right up in the north-western part of the Colony. In the creek where the banks on both sides are very high and rocky, a large body of water could be conserved by a dam at the lower end of that water-hole. The Wampah. Dam.
7536. What area of water could be conserved? The length of a full mile. Back water.
7537. By what width? By a width I suppose of 2 chains. Width.
7538. That would not be a large conservation? The depth would be great.
7539. To what purpose could the water so conserved be applied—could it be diverted into any of those lakes? No; only for local purposes. From the Wampah water-hole the creek is well defined. It runs down past the point of Mount King, where another creek comes in from the west, after which it forms itself into what is called the Whittabreena Creek. Whittabreena Creek.
7540. Are those creeks shown on any map? Not that I know of. After that it heads away down, and I believe runs into the Yantara Lake.
7541. Have you any idea how often the Wampah Creek runs? It only runs after heavy rains. The heads come in from Queensland. I believe it is part of the Booloo. Supply.
7542. Is it east or west of Carypundy Swamp? It is west. The overflow from the Yantara Creek runs into Tarawoto Swamp. The water I believe runs from Tarawoto Swamps into Yancanya Creek. A little further on, beyond Yancanya Creek, and between Yancanya and Tonga Stations, there are high ridges, to the south-east of which and into the Momba, at the lower end of the Paroo watershed, I believe the water from Yancanya Creek runs. Tarawoto Swamp. Yancanya.
7543. Can you suggest any means by which the flow of that water into Yantara Lake could be facilitated? No. I may mention that when the country near the Wampah is fully stocked there can be no doubt that the ground, which consists of stony ridges, will cause the rainfall to flow more readily into the creeks I have described.
7544. Have you anything to say with reference to Cobham Lake? That lake is filled from Evelyn Creek. At the head of Evelyn Creek is the Depôt Glen waterhole, which is in a deep gorge between two very steep slate hills. A large quantity of water could be conserved there by means of a dam at the lower end. Evelyn Creek.
7545. What length of dam do you think would be required? One from 2 to 3 chains wide. The sheet of water in the hole is upwards of a mile in length. Dam.
7546. Over what area of country would a dam throw the water? It would not throw the water back far, because the country rises at the back. Back-water.
7547. What is the height of the banks? Between 50 and 70 feet high.
7548. If the dam were made up to the height of the surrounding ridges, what area of country would be covered? Not a large area, because the country falls very quickly. It would be about 10,000 acres. Area.
7549. To about what depth? The channel above Depôt Glen is about a mile in length. Depth.
7550. But would there be 10,000 acres of this deep water? No, it would include the deep water and the water at the back. A high dam would throw the water round the head of the waterhole. It has a good large watershed, because there is a sort of natural creek or watercourse, running into it for 5 or 6 miles.
7551. About how many miles square would the watershed be? About 5 miles square. The question of damming this creek would be of sufficient importance to justify further consideration, as it is the main supply for the stock of people living in that part of the Colony. Watershed.
7552. But you only consider it is worth troubling about for storage for the immediate use of stock and residents? That is all. Purpose of storage.
7553. Not for the purpose of irrigation? No. Below Depôt Glen, just opposite Poole's grave, there is another good water-hole in Evelyn Creek. These are the holes that Sturt and his party were camped at for twenty-one months in 1840 and 1841. They could not get away, owing to the want of water. They had taken a boat out with them, believing the whole place to be an inland sea; and that boat, I believe, was on the water-hole opposite Poole's grave when Mr. J. C. Woore visited the place in 1863. After that date I believe the boat was washed down the creek and broken up, thus showing that there could not have been any floods between 1843 and 1863, or else the boat would have been previously washed away. About 4 miles further down the creek, on the left bank, there is a well 90 feet deep, containing a supply of beautiful water. That well has been used to water stock, and I believe has never gone dry. Water-holes. Floods. Well.
7554. What quantity of stock would it water? I should think it would have watered 10,000 sheep. Supply.
7555. Is the well in existence now? It is still in existence. It was the only well the gold-diggers could get their water from. 2 miles lower down, at Milparinka, there is a very fair water-hole, where a large quantity of water could be stored by the erection of a dam. Milparinka. Dam.
7556. What height would the dam require to be? You could make it as high as you please. In Evelyn Creek there is a well-defined channel all the way down to Cobham Lake. That lake was dry about 1882. The overflow from it runs south-west.
7557. Is there any means of damming the water in Cobham Lake, so as to make it permanent? No, I do not think so. Cobham Lake.
7558. Can you suggest any means by which Cobham Lake could be made permanent? No, I could not suggest any means at all. There is a salt lake east of Cobham Lake, or a little to the north-east. The water in it is as salt as the sea. That lake gets its drainage from the north-east. Salt Lake.
7559. Is there any means by which the drainage into that lake could be taken into the Cobham Lake? Yes, I am sure of it. As you ride along you pass a number of hills, and if you could cut one of these Diversion.

hills

Mr. G. C. Tompson. 27 May, 1885.

hills off you could divert the watershed from the north portion of the salt lake into Cobham Lake; but it would not be worth while, because Evelyn Creek in heavy rains fills Cobham Lake.

7560. Could you not dam the outlet to Cobham Lake? Yes, you could by an overshot dam. An earthen dam would break over the sides, and carry away down the overflow creek.

Boulka Lake.

7561. Then you do not think there is any means of improving that lake? None. Boulka Lake is a very good one; it is on the border between New South Wales and South Australia. The creeks flowing into that enter from the north.

7562. Is that a permanent lake? No.

7563. Are there any means of making it permanent? I could not say. I have never been at Boulka Lake.

Well. Rise.

There is a good well at Mount Stuart Run, 138 feet deep, which strikes a splendid supply of water 104 feet 6 inches from the surface. The water will rise in the well 31 feet in one night.

Well.

7564. Do you know what formation is passed through in the well? I do not now remember the strata.

7565. Do you know any other well out there? Yes; there is another well on Sturt No. 4 Block. The lessees put down a well, and struck a fair supply of water at a depth of 130 feet. There is a good well at the head of Bunker Creek.

Warrego overflow.

7566. Do you know any other water? Not in that part. The overflow from the Warrego in Queensland comes down through North Darling back block No. 10, and North Darling back block No. 15, into a cane-grass flat. That water could be brought down on to the North Darling back blocks.

7567. Does any quantity of water come down there? Yes, I have seen the water run in regular creeks through these blocks.

Springs.

7568. Are there any wells up there? Yes. There is a spring at No. 16 called Shearer's Spring, and there are some good springs on the North Darling back blocks Nos. 12 and 18. On No. 17 there is also a very good spring.

7569. Are these mud springs? No; you just open them out and the water runs.

7570. What sort of springs are they? They are all rocky springs, and when opened out the water runs from them.

Supply.

7571. Is there any quantity of water? There is one spring that watered 7,000 sheep; the others are not so good.

Quality. Warrambool from Balloon.

7572. Is the water good? Excellent water. There is a warrambool coming from the Balloon, west of the Mooni; I have seen that running; it runs right round, coming in just on the boundary between Millera and Boorroomma. I have seen that running in a regular channel the whole way down into the Barwon. There are also splendid wells on Burrawandool and Boorara Runs.

Wells.

7573. Are they deep or shallow wells? Shallow wells, in a sandy drift; they furnish a splendid supply of water.

7574. Are they artesian? No; the water remains in the shaft. On Muggarie back block B there are splendid wells; also on Pinegobla and on Bukkulla.

7575. Then on the whole, in this country lying between the Narran and Barwon, water is obtained in numerous shallow wells? Yes, it is obtained chiefly in gum sand-ridges. There are wells at Dungalear back block No. 3, and on the Plumbola blocks. There is a good spring at Camborah, and a capital natural water-hole at Grawin. There is also a capital warrambool which comes out of the river Barwon just at the top boundary of Dungalear, and runs out about 4 miles from the river and into the river at Ulah, a distance of about 40 miles. There were two dams on that warrambool, which threw back a large quantity of water, but they were carried away in the 1876 flood. The water was over the whole surface of the country; it was a sea of water right up to Ginghe, on the frontage.

Protection of dams from floods.

7576. What means could be adopted to prevent a repetition of the washing away of dams like that? Only by protecting them with stone sides.

7577. That would protect them you think? Yes.

7578. And making a by-wash? Yes, of course. You could flood all the country between the warrambool and the Darling. At that time I went from Ginghe Station up to the town of Walgett in a boat across country; the distance is about 4 miles.

Natural basins. Overshot dams.

7579. There are large natural basins for conserving water in the warrambool, by making dams? Yes, generally the creeks going through that part of the country should be dammed with overshot dams—not earthen dams. I have never approved of earthen dams, because they are too costly for repairs, and the earth that goes into the channel of the river helps to fill it up. The Mara also requires to have overshot dams; at present there are earthen dams there.

7580. Have you any theory with reference to the underground water which produces the mud springs between this and the Queensland border? No.

7581. But you know of their existence? Yes.

7582. And they are found in a number of places? Yes, they are.

Mud springs.

7583. *Mr. Gipps.*] Are there many of these mud springs on the west of the Darling? On the north-west side there are a great many of them.

7584. You could not travel any great distance without coming on them? They are isolated.

Wind.

7585. What is the prevalent wind in the summer, west of the Darling? From south-west to north-east chiefly.

Windmills.

7586. Are they sufficient to admit of windmills being used? Yes.

Rain-wind.

7587. What is the prevalent rain-wind? The north-east.

Irrigation.

7588. In both summer and winter? Yes; that is for general rain—thunder-storms come up from anywhere. I may mention, with reference to irrigation, that it was tried on the black soil at Winbar and proved a failure. They put a large steam pump on to a lagoon to pump the water towards the river over the low-lying land. No grass grew there afterwards. The lignum became green, but no grass ever grew. The lucerne in a paddock, over which water from the river was pumped, grew splendidly.

7589. *President.*] Do you think irrigation could be carried out to any reasonable extent if there was plenty of water at command either on the frontages or back country? Of course, if you had sufficient water you could always make any thing grow on the back country.

7590. But how about the frontages? On the frontage the soil is of a very saline nature, and it does not seem to answer very well.

7591. Do you know of any other instances on the frontage where the surface of the soil has been prepared for irrigation—either scarified or broken? No.

Mr. G. C. Tompson. 27 May, 1885.

7592. And your experience relates simply to places where the water has been thrown over the natural surface? Yes.
7593. Do you know of places on the frontages where Chinese and others have gardens? Yes.
7594. Do they irrigate with river water? Yes, and with the well water. The river water is far preferable to the well water.
7595. But both will produce vegetation on the frontage? Both; but the ones watered from the river produce better vegetables than those watered from wells.
7596. But suppose irrigation were tried on the frontages on a large scale, and under a system of ploughing or scarifying, do you not think the water would have the same effect as in the Chinese gardens? Yes, it might have.
7597. And the reason you consider that it has not that effect now is because no pains are taken to prepare the soil for the water? I think that is it.
7598. If there were plenty of water at hand, do you think the squatters and others would take advantage of it? I am sure they would—that is by an easy process—just letting it on; they would not go to any expense in putting it on.
7599. But if they went to any expense, it would be a calculation whether it would pay them; if it would pay them they would do it? Yes; but now the railway is out here it would not pay them.
7600. What do you estimate would be the cost of growing hay if water was at command? It would all depend upon how you put the water on. Cost of hay.
7601. Supposing it were put on without undue expense, say at a cost of £1 per acre per annum? 40 acres would produce from 80 to 120 tons of hay in the year if the land were irrigated once a month during the time the crop was in.
7602. But what would be the cost per acre of dealing with the land and taking the hay off? About £2 per acre.
7603. That is, to put in the crop and take it off? Yes.
7604. You say that 40 acres would produce from 80 to 120 tons, or 3 tons to the acre, and that the cost of putting it in and taking it off would be £2 per acre—that would be about 13s. per ton? Yes; in fact there is some land in the county of Mouramba which I am confident grows a crop of 4 tons to the acre.
7605. *Mr. Gipps.*] In one crop? Yes. I have seen oats as tall as I am growing there.
7606. If the cost of irrigating the land is estimated at £1 an acre, that would make the cost of producing the hay £1 a ton? If it cost £1 an acre to irrigate the land, the hay would cost about £1 a ton to produce.
7607. What is hay worth here? About £10 a ton.
7608. *Mr. Barton.*] Speaking of the rainfall here, you said it was not sufficient to grow wheat: do you know what the rainfall is in the north of Adelaide, where wheat crops are grown successfully? I have no idea. Rainfall.
7609. Do you not think that if the rainfall here, or even less, were regular, we could produce cereals? Yes, if we had the rainfall. The rainfall here averages only 13 inches in the year.
7610. I think you will find that Mr. Russell's record shows 20 inches? I always thought it was about 13 inches. Of course this year has been an exceptional one. I am speaking of the country out back—not that on the frontage. I always considered the rainfall there about 13 inches in the year. But even if we could have the 13 inches within three months we could grow anything at all; but when it comes in 20, 30, or 40 points it is of no use at all.
7611. Do you not think that cereals could be grown in favourable positions here three years out of every five? Yes. Cereals.
7612. Are you aware that at the Shearlegs, 30 miles the other side of Cobar, they have grown crops every year without fail for the last seven years? Yes.
7613. Are you aware that they have cut this year already as many as three crops of lucerne? I am not aware of it, but I dare say they have.
7614. Without any irrigation at all? Without any irrigation. I may mention the Shearlegs lies in a flat, and that it has been proved that a sort of drainage passes underneath the flat.
7615. Do you not think that there are other flats in the same position to be found if you looked for them? I am sure of it.
7616. You said that the Gongolgan water-hole was formed by a natural bar of rocks, or natural overshot dam? Yes. Gongolgon waterhole.
7617. Do you consider that the fact of the Gongolgan water-hole not silting up would of itself prove that if overshot dams were erected at suitable places they would not silt up either? No, they would not—the current would carry any silt over. Silt.
7618. Have you seen any silt in the Bogan except the very fine mud held in solution? No, I have not.
7619. *Mr. Gipps.*] You say the current would carry the silt over; but how about the spot in the river where the back-water would be first filled? It rises pretty high on the overshot from the head of the Lachlan, and there is a tremendous current in the Bogan when it is in flood, and any silt would be soon swept down. The silt is more likely to lie in the Darling. In the Bogan, you can take your horse in the water without fear of his being bogged; but you could not do that in the Darling, which shows that the silt in the two rivers is different. Current in the Bogan. Silt.
7620. What is the character of the soil? In the Bogan it is sandy, but in the Darling it is muddy. There is a greater fall in the Bogan, and the current carries it off. Soil.
7621. *Mr. Barton.*] Do you think that if there had been railways communicating with the far west, they would have been the means of saving large numbers of sheep which have died in consequence of the drought? I am sure of it. Railways
7622. And do you think that it would be good policy on the part of the Government to provide means of transit for sheep from those places to other places? I think so. Transit for sheep.
7623. Do you know the present Travelling Stock Act well enough to say whether you think it presses hardly on squatters when they want to travel their stock to feed them? Yes, very heavily indeed; because you might be suffering from a drought on your run, and if you can't get any paddocks within 40 miles of you you have to take your stock over that distance, and then remain away several months before you can return to your station. Travelling Stock Act.

Mr. G. C. Tompson. 27 May, 1885.

7624. Do you think it would be wise to alter that Act so as to allow squatters to move their sheep anywhere and bring them back after rain? Yes.

7625. And do you think it would be wise to grant power to the Sheep Boards in any district to give permission to remove stock from one place to another, in order to save their lives? Yes. From what I know of the Sheep Boards, they would be suitable persons to whom to entrust that power.

Legislation.

7626. *President.*] Do you think it is necessary to legislate for the purpose of giving water rights or regulating the distribution of the water from the various watercourses throughout this Colony? I think it would be a very good plan indeed. For instance, supposing a person is situated here on a creek, if he makes a dam to conserve storm-water, he should for a certain number of years at any rate be entitled to (say) 3, 4, or 5 miles of the water, as the case might be—in consideration of his expending a sum of money in putting a dam across the creek.

Rights to water.

7627. But the question is as to dealing with rights above or below points where water is conserved. Supposing a man puts a dam across a creek or river, the man below may think he has some rights taken away: do you not think that a law should be passed regulating those water-rights, so that there could be no dispute? Then they should be overshot dams, so as not to divert the flood-water from the channel. A man should be allowed to keep the channel full, but not by means of large earthen dams to throw it back for miles. On Pine Creek, between the Namoi and the Gwydir Rivers, on the Burran Burran Run, a large dam was constructed which never let the water get below it.

7628. And you think there should be legislation to regulate water-rights generally? Yes, I always thought so; that was proved on these rivers wherever people put large earthen dams.

Mr. John Little called in and examined:—

Mr. J. Little. 27 May, 1885.

7629. *President.*] Where do you reside? At Curraweena, in the Bourke district.

7630. Do you know anything concerning the Yanda Creek? Yes, it goes through my run.

Yanda Creek.

7631. What is its source? I believe its source is near Cobar; I have never traced it beyond Cobar.

7632. Is the country beyond Cobar much higher than the Yanda Creek where it goes through your run? Yes, I think so.

Dams.

7633. Are there many dams on Yanda Creek? I know of five.

Back-water.

7634. Do they back up any large quantity of water? After the rains of January they did; I never saw so much water in the creek as there was after the January rains.

7635. Is the water permanent? I do not think it is.

Depth.

7636. To what depth do these dams back up the water? 10 or 15 feet above the excavation. I have an excavation in front of the dam, and the dam is made of the earth from the excavation.

Banks.

7637. What is the reason why you do not think the water is permanent? In prospecting for a site for the dam I have found the banks to be in drift, made by the action of the water at some time or other.

Soakage.

7638. And do you find that the water soaks away? Yes, until it gets into the excavation, and there it stands. The surface above the bed of the creek consists of drift, which allows the water to go through. I made puddled drains at the base of the dam, filled up with good clay. In places I went from 2 feet to 15 feet in these puddled drains before I could get suitable holding-ground; the sand would hardly stand while the men were doing the work.

7639. Then before you could construct permanent dams on the Yanda Creek you would have to adopt some means to prevent the water from percolating through the porous strata? Yes.

7640. And your experience is that it does get away? Yes, quickly.

7641. But the ground, when excavated, holds well? Yes.

Banks.

7642. Is the creek of any size? It is pretty shallow. The banks are not very high on each side; but during the January rains, when you could see the extent of it by the water, it had the appearance of a stream like the Darling itself in ordinary times—wide, but shallow.

Country.

7643. What is the nature of the country about the Yanda Creek? Undulating.

Storage.

7644. Do you know of any points on the creek where large quantities of water could be stored between ridges or anything of that sort? No; the creek runs through undulating country, but the ridges are not of any size to permit of a dam stopping any large quantity of water.

Soil.

7645. What is the nature of the soil? It is red, porous subsoil—a good rich soil.

7646. It would produce, with plenty of water, a large amount of vegetation? I cannot speak from experience, but I should say so. You can get any quantity of vegetables by giving water.

7647. Is it good wheat-growing soil? I think so.

Value of land.

7648. What is the difference between the value of the country improved and unimproved? Unimproved it is valueless, or was when there was very much of it unimproved.

7649. And it is of considerable value when fairly improved by the conservation of water. Oh yes.

7650. And I suppose the improvement varies in value according to the quantity of water that can be stored? Yes.

7651. That is, the improvement over the whole of the country? Yes; the drawback is in the water being so scarce.

Wells.

7652. Do you know of any wells in the neighbourhood? Yes; I sank three wells on the Glenariff country.

Quality.

7653. With what result? The result was water, but it was not good. It was salt water, or water containing some mineral substance which made it unsuitable for sheep or stock, and the supply was inadequate for any large number.

7654. It was a pure supply of water? Yes, in all cases.

Depth.

7655. Have you sunk to any great depth? The deepest well was 280 feet.

Bed.

7656. What was the bed you came upon? Granite; I sank 100 feet through the granite.

7657. Do you know of any wells in the neighbourhood of the Yanda Creek? There is an old shaft on Curraweena on Yanda Creek which was sunk to a depth of 80 or 90 feet, and tapped salt water. It was not persevered with. I do not know anything about the supply, but the quality was not suitable for stock.

Supply.

7658. Do you know of any instances where wells have been sunk down to the granite, or where a plentiful supply has been obtained? In my own case I went to the granite and into it 100 feet, but I did not get a supply. I do not know any other place where a plentiful supply of good water has been got in any well between the Bogan, the Darling, and the Lachlan.

Mr. J. Little. 27 May, 1885.

7659. Then do you consider that any large quantity of water to be stored in or diverted into that country must be over the surface by means of a canal from some river or by tanks and dams? I would rather say that I believe it could be accomplished by artesian borings; it is my impression that there is an artesian supply of water in the locality if it could be reached. Artesian supply.

7660. And do you think it is worth while to prospect for artesian water? Yes.

7661. And after that the only other means is to conserve as much surface water as possible? Yes. Surface water.

7662. Suppose you could divert a portion of the Darling, the Macquarie, or the Bogan waters through that country, do you think it is practicable to convey it in a canal, or do you think the evaporation or soakage is too great? The evaporation of water is great, but the supply of water might be greater; it would depend upon the supply. I have no doubt that if a canal were made the water could be supplemented by the drainage from favourable spots along the route. Diversion. Evaporation. Canal.

7663. By storing water to supplement the water in the canal? Yes.

7664. All along the course of the canal? Yes.

7665. *Mr. Barton.*] What kind of places do you mean—springs? No; there are no springs in this district. Yanda or Mulga Creek might be utilized in that way.

7666. *Mr. Gipps.*] But you said that the soil was porous for some feet? There are other flats where a large quantity of water could be conserved and led away in the manner I speak of. I am speaking of the country between Nymagee, Cobar, Nyngan, and Bourke. Porosity of soil.

7667. There are no natural features to prevent a canal from being taken through that country, if the levels do not prove that the country is too high? No. Canal.

7668. The surface water is suitable? I think so.

7669. *Mr. Murray.*] With reference to the carrying capacity of these 10 mile blocks, do you know what the average stock on them is at the present time? It is very much below their capacity. Stock on runs.

7670. What would you say was the average quantity of stock these 10-mile blocks are carrying now? 10,000 I should say, at the outside.

7671. Is that an increase on former years? No, it is a decrease.

7672. What have they carried? 15,000.

7673. How long ago was that? Say from 1879 to 1882.

7674. Can you go back as far as 1875 and say what they carried then? No; as far back as 1876 there were very few runs in the country carrying anything at all.

7675. Then from 1879 to 1881 they were stocked up to about 15,000? No, they were not stocked up at that time; the lessees were improving—making tanks and fencing.

7676. When did they reach their maximum capacity? In 1882.

7677. And the falling away has been due to the drought which has occurred since? Yes.

7678. Was it as much want of water as want of grass that caused the falling off? Both in about an equal degree.

7679. If you had plenty of water, could you keep up your stock with the salt-bush and other edible herbs? No, I do not think so. These herbs suffered from the want of natural moisture, and in many cases were not palatable to the sheep.

7680. You think the runs are not stocked up now to their full carrying capacity? No.

7681. To what extent could they be stocked? To a third more than the present quantity.

7682. They have been stocked up to one-half more? Perhaps. There are instances in which they were stocked up to more than they would carry. The country was young, and perhaps was in a condition to carry more than it ever will again.

7683. Have you ever suffered from want of water in this district when you had plenty of grass? Yes. Water and grass.

7684. Then you think it might be of advantage if this country could be supplied with water? Decidedly.

7685. Then though you might have a dearth of grass you would keep a greater quantity of stock? Yes, the stock would be better distributed over the country if there were plenty of water; instead of going to one place for water, they would have different points to go to without having to travel far.

7686. Have you made any observations with respect to evaporation? No, but I know it to be great. Evaporation.

7687. Take a dam of 20 feet: if the water were not used for stock, how long would it remain before it evaporated? It would last through any drought, unless the soil were porous.

7688. The percolation is not very great? It depends on the nature of the soil; it is difficult to find suitable soil for holding purposes. Percolation.

7689. *Mr. Barton.*] You have had a great deal of experience in this back country during a number of years, and in other parts between here and the Lachlan? Yes.

7690. And you were connected with squatting a great many years previous to that? Yes.

7691. What do you consider to be the highest commercial value of any unimproved block of country between the Darling and the Lachlan, or the Darling and the Paroo? The value of the blocks depends upon the facilities for making water. Value of blocks.

7692. I am speaking of unwatered blocks? Well, it would depend upon the natural facilities there were for making water on the blocks.

7693. Well, take the best of them, or a fair average of them? £1,000 I should say was the value of any block in its natural state.

7694. *President.*] That is a 10-mile block? Yes.

7695. *Mr. Barton.*] What do you consider it would cost, on the average of the back blocks you have seen here, to provide permanent water for all the stock you ought to carry on 100 square miles? To improve it up to my idea of what it should be, I should say it would take £4,000. I should think it would take six tanks distributed over a square block, at a cost of about £4,000. Cost of water conservation.

7696. You are aware of course that in this district, and over a great part of the western country, more than one-half of the sheep have been lost during the late drought? Yes.

7697. Do you think that if there had been railway communication into the far west, it would have been the means of saving a large proportion of the sheep that have perished? Yes, I think so. Railways.

7698. Are you of opinion that it would be a wise policy to make special arrangements to provide for the transit of sheep in great droughts? I am.

7699. Are you of opinion that the Travelling Stock Act presses very heavily on squatters in time of drought, when to travel their stock to a distant district is the only chance of saving their lives? I am. Travelling Stock Act.

Mr. J. Little. 27 May, 1885.

7700. Are you of opinion that it would be wise in the Government to place in the hands of the various District Sheep Boards the power to grant permission to travel stock to other districts for the express purpose of saving them, and to regulate their return? Yes; their practical knowledge would guide them in deciding whether it was or was not wise to do so.

Temperature. 7701. *Mr. Gipps.*] What is the highest temperature you have known, east of the Darling? 124 degrees in the shade.

Hot winds. 7702. Are hot winds frequent? No, they are not frequent.

7703. Nor continuous? No.

7704. What effect do they have on vegetation—on the grass, scrub, and trees? A very withering effect. You may see by the vegetation the effect of a hot wind, immediately it has passed by.

Springs. 7705. Do you know of any springs east of the Darling? No.

Overshot dams. 7706. Are the dams in the Yanda Creek overshot? No.

Silt. 7707. Do they silt up or raise the bed of the creek at all? I have not had an experience sufficiently long to enable me to say. The Yanda Creek has only run once during my knowledge of it.

Ground. 7708. What is the character of the excavated ground? It is good holding ground in the bed of the creek, and generally black soil where the dams are put, that being the best soil for holding.

7709. That is beneath the porous soil that you said could not hold water? Yes, the porous soil is on the banks on one side or the other.

Water-holding capacity. 7710. Then comes the black clay, which is good holding ground? Yes, black or red clay.

7711. *Mr. Targett.*] Does the red soil hold water well for tanks? If you get a certain depth, from a foot to two feet from the surface; but it is generally of so porous a nature that it does not hold water. In many instances puddling drains have been made outside the dam to this depth to get the water.

Puddling. 7712. Is it usual to puddle? No, it is only in exceptional cases that it has been tried.

7713. Does it improve it much? It depends on how it is done; if it is done with good clay, and faithfully, it does improve it.

Soakage. 7714. It does away with almost all soakage? Yes, there is nothing lost except by evaporation.

7715. If there were plenty of water in the country you refer to, for irrigation purposes, do you think any of the lessees would grow fodder? I think they would all avail themselves of the privilege to the greatest extent, and they would be prepared to pay a reasonable rate for water.

Winds. 7716. *Mr Gipps.*] What are the prevailing winds in summer and winter? Westerly winds. The north-westerly winds bring the dust-storms. The south-westerly winds in the winter are cold and dry.

Windmills. 7717. Are they frequent and continuous, so as to be suitable for windmills? The westerly winds are. The prevailing winds are from the north-west and south-west, in winter.

Rain. 7718. *Mr. Targett.*] What winds bring the heaviest rain? The north-east winds.

Profit per sheep. 7719. *Mr. Murray.*] What do you think is the profit per head on sheep in a fair average season? It is so long since I saw any profit that I could scarcely answer that question right off. When the country I am in was in a condition to yield profit the drought came and obliterated all hope of profit.

7720. *President.*] But take a fair season? I will say 3s. per head. The quality of stock and other conditions would raise the profit probably above that, but that would be the average.

THURSDAY, 28 MAY, 1885.

At Nyngan.

Present:—

MR. GIPPS, C.E., | MR. M'MORDIE, M.I.C.E.,
MR. LYNE, M.P., | MR. MURRAY, M.P.,
MR. TARGETT, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. John Readford called in and examined:—

Mr. J. Readford. 28 May, 1885.

7721. *Mr. Murray.*] How long have you resided in this district? Forty years the 14th of last month.

7722. Then you know a great deal about the district? Yes, I do; I was down within 3½ miles of Murrawonga (Richardson's place) in 1845.

7723. Do you know the Macquarie particularly near Warren? Yes.

Macquarie floods. 7724. Have you seen the flood-waters of the Macquarie passing into the Gunningba Creek? Yes, and likewise into the Beleringa Creek.

7725. Do you think it is practicable to draw the Macquarie water so as to get a supply in these creeks? I think so. I have seen the river several times in the year within a foot of running into them. If there had been a dam across, the Macquarie would have filled it and irrigated a large extent of country as well.

7726. Do you think it is possible in the same manner to get the supply in the Bogan supplemented from the Macquarie? 7 miles above Warren would be the place to put one of these dams.

7727. Warren is on the Macquarie? Yes; but you must recollect that there are two Warrens, one on the Castlereagh, and one on the Macquarie. A dam there would throw the water into the Gunningba Creek, and also into the Beleringa Creek. Both of those creeks run into the Bogan.

Permanent supply. Irrigation 7728. If a permanent supply were maintained at a high-level in the Macquarie, and also in Beleringa, Gunningba, and Duck Creeks, do you think that irrigation could be tried in many places? I think so; the water would irrigate of itself to a large extent. It would be about 3 miles on each side of the river, and the further you went down the wider it would get.

7729. *Mr. Gipps.*] How would you carry out the irrigation? By weirs and sluice-gates to let the water off as required. People who have come from England have told me that it would have been done there long ago.

Supply. 7730. *Mr. Murray.*] If the Macquarie were dammed, would it be practicable to draw a supply from the east side of the river as well as from the west? Yes.

Dam. 7731. *Mr. Gipps.*] What height would the dam require to be? A little higher than the bank, which is 17 or 18 feet high.

Mr. J. Readford. 28 May, 1885.

7732. Do you know of any lagoons or natural reservoirs, such as depressions, in the neighbouring country? Yes. The Bird's-nest on the Beleringa Creek, and the Burlong Hole. The Burlong Hole holds water for two and a half years, and the Bird's-nest will hold it nearly three and a half years.

Holding ground.

7733. *Mr. Murray.*] As a rule, does all the country between the Macquarie and Bogan retain water well? It holds it very well; the cattle have puddled it to a considerable extent. When first I came here it would not hold. That country as a rule does not hold water because it is not puddled. I have seen the Beleringa Creek run with local rains, and I have seen it running in the winter-time and dry in February. Some of the holes will hold water eighteen months.

Water and grass.

7734. Have you suffered much from want of water in this district? Yes, but more from want of grass. When the holes I have been speaking of are full they will hold out longer than the grass. The greatest drought I ever saw here was in 1851, when the diggings broke out. I lost 2,500 head of cattle in no time.

Mara Creek.

7735. Do you think that works such as have been mentioned are necessary for the development of this country? I think so. There is another place at Mumblebone, 20 miles below Warren, on the Macquarie; a dam there would fill Mara Creek and would back up the river I should think 10 miles or more.

Wells.

7736. Do you know anything about the wells? I know a few at Nevertire. There is one 160 feet deep on Ryrie's run, but they only get a little water out of it; it was not bad water.

7737. Are there many wells in the district? I have tried one about 5 miles on the west side of the river, and got very good water at a depth of 44 feet—4 feet of permanent water.

7738. Are the wells in the vicinity of the Macquarie affected by the rise and fall of the river? Some are, and some are not. Down along the river there is gum, and wherever there is gum you can get water.

Supply.

7739. Have you ever tested any of these wells to know what their capacity is? The only one I tested was one at Warren; you could draw night and day at that without bringing it down an inch.

7740. Can you say what quantity of stock could be watered from that well? I think it would water any amount of stock if the water could be pumped out. The well is 150 yards from the bank of the river.

Wells.

7741. Do you know of any wells back from the river? I know of one at Nevertire, but I do not know what water it contains. I know a well that was put down on the Marthaguy Creek a depth of 180 feet, but there was no water in it. Mr. M'Gregor sank one at Merrigale on the Duck Creek, 7 miles from where the other was sunk, and he got very good water at 180 feet.

Bottom.

7742. *Mr. Gipps.*] Are those wells bottomed on rock? It is a hard substance, but I forget what sort of material it is. In the well I sank at Warren we came on a sort of sand rock.

Rise.

7743. Did the water rise in the well? As soon as the sandstone was struck the water rushed in up to the neck of a man who was working there; the water came in almost as soon as he struck his pick into the sandstone.

7744. Did the water rise to any height in the well? 35 feet.

7745. How far from the surface? 65 feet was the depth of the well, and the water rose 35 feet and kept at that for some time.

Supply.

7746. You could not pump it lower? They tried with buckets night and day for two days and a night, but could not reduce the water. That well is within a few yards of the Macquarie River. Anywhere within 8 miles of the river any person can get plenty of water, but back from there you cannot. The well in which I got 4 feet of water is 8 miles back from the river. The supply there was all that I required, and I did not try to go lower. On Day's run they have watered a place called Trowan. They got it at a depth of 18 feet. It lasted very well for some time; but there is gum there. In some of the wells about Warren you go through a lot of drift, and in the well I am speaking of they went through a sort of clay all the way down until they came to the sand-rock.

Strata.

Water conservation.

7747. In your opinion, what is the best system that could be adopted in this district for the conservation of water? I think the best thing would be to try to put those two dams we were speaking of.

Sites for dams.

7748. If these dams were constructed, to what distance from the river do you think they would be able to supply water? I think the best place to put a dam would be in the river, because that would give a continuous supply. You could make the water flow into the creeks I have spoken of.

7749. Are the banks of the Bogan higher than the country at the back? I do not think you could do much there. The place to dam the Bogan would be where those half-moon places come out, about a mile or half a mile away; that is the best place for a dam to keep the water in the river; but I do not think you could send the water far out on the plains. I have seen the river in a flooded state, but the water was never far back from the river.

7750. *Mr. Targett.*] Where would you propose to tap the Macquarie to fill the creeks? 7 miles above Warren for the Beleringa and Gunningba Creeks, and 20 miles below Warren for the Mara Creek. Further back than that you want tanks, because you cannot throw the water from the river without great trouble.

Tanks at Nevertire.

7751. Will tanks hold well? Yes, if you put them in the red ground, but they will not last any time in the black soil. You need to look for a good catch. The first tank I sank at Nevertire I paid 3s. 6d. per yard for the excavation, and during the drought of 1866 it watered 300 head of cattle and 300 head of horses. In my opinion, a tank of 10,000 yards, when the water is pumped out of it, will hold more water than an 18,000-yard tank into which the stock are allowed to go, because the stock take as much out on their carcasses as they drink. I used to keep a man on purpose to pump the water into troughs as it was required.

Evaporation.

7752. *Mr. Murray.*] Is the evaporation very great here? It was not in the tank I am speaking of.

7753. How long did the water in the tank last without rain for the number of stock you had? For eighteen months we had no rain.

7754. And you had water all that time? Yes, the tank never was dry while I was there; but after I left, a lot of sheep were allowed to go round it and the manure ran in. I had fenced it in, and would not allow a beast inside the fence. It would not have been dry now only for that.

Pumping.

7755. Then you think that a dam will last a great deal longer if you pump the water out of it to supply the stock than if you allow the stock to go in? Yes, I am sure of it, and pumping is easy; I had a Californian pump.

Dams.

7756. Do you know of any other dams in this district? No, I have never been out to any other dam. I know that Mr. Flood has a dam that never went dry on the Merri Merri, and there is one at Bungle Gully, Evans's place, between the Castlereagh and the Namoi. That has been there for years, and never went dry; it throws water back 12 miles, and is the smallest dam I ever saw; it is not more than 10 feet across.

Mr. J. Readford. 28 May, 1885.

7757. *Mr. Targett.*] Had it a by-wash, or was it overshot? I do not know; I only saw it as I passed. It is twelve or thirteen years ago since I was there.

7758. Is it still in existence? Yes.

7759. What area of country does it throw water over? I do not know; I only went past it.

Width.

7760. How wide is the water at the dam? Not very wide—about 20 yards; but when you get higher up it is wider—so wide that they have to keep a boat.

7761. What was the width at the place where you saw it? 50 or 60 yards I should think.

The Macquarie.

7762. *Mr. Gipps.*] Is the Macquarie always flowing at the sites you propose for the dams? No; we get floods perhaps five or six times a year, and sometimes we are short. The Macquarie will not hold water a long time.

Silt.

7763. Does much silt come down the Macquarie in flood-time? Yes, there is a great deal sometimes.

7764. What is its character—is it sandy? Yes.

7765. Do you know of any springs in the district? No.

Winds.

7766. What are the prevalent winds in summer and winter? From the west or south-west, and we never get any rains with these winds.

Windmills.

7767. Are the winds continuous, so as to allow the use of windmills? Yes, they are.

Diversion.

7768. Would the diversion of the Macquarie into the creeks deprive the channel below of water? No, the water would run in again from the creeks, and if there were flood-gates there the water could be regulated.

Waste of water.

7769. *Mr. Targett.*] I suppose a great quantity of water runs to waste in flood-time? Yes, it runs into reedy marshes.

Sluice gates.

7770. *Mr. Gipps.*] Do you think that the use of sluice-gates and an overshot dam would influence the flow of the water down the Macquarie? No, I do not think so.

7771. How far is it from the place 20 miles below Warren to where the Mole dips? It is about 60 miles, or nearly so.

Waterholes.

7772. Are there deep waterholes between the proposed dam and the end of the Mole, in the river? Yes. There is the Graway Water-hole—that is a large hole I have never known to be dry; it is like a natural dam.

Rocks.

7773. Are there rocks near? I do not know—I never examined that point. The place where Beleringa Creek forms is 8 miles above Warren, and it runs into the Gunningbar Creek, 25 miles below Warren.

Beds of creeks.

7774. What is the character of the beds of these creeks—sandy? Yes, but not much in the Beleringa Creek. There is a little in the Gunningbar Creek—it is what is washed out of the river. That creek overflows nearly opposite to Cannonbar; some part of it goes into the Bogan, and some part into Duck Creek.

Mr. T. L. Richardson called in and examined:—

Mr. T. L. Richardson. 28 May, 1885.

7775. *President.*] You are an old resident here, Mr. Richardson? Yes, I have been on the Bogan since 1860.

7776. And you have station property in the neighbourhood of the Bogan and Duck Creek? Yes.

7777. The Duck Creek runs into the Bogan? Yes.

7778. Does it come out of the Macquarie? Yes.

Duck Creek.

7779. Is it a running stream always, or only in flood-time? Only when the floods are coming down, or after heavy rain.

Dams.

7780. Is it dammed to any considerable extent? I think there are only one or two dams on Duck Creek. There is a small and overshot dam below Cannonbar—the country there is perfectly flat.

Back-waters. Fall.

7781. Do the dams back the water any distance? Yes; the country has such a slight fall, not more than 3 feet in the mile. I have dammed the water back for 5, 6, and 7 miles, that is, on Duck Creek. Duck Creek is the biggest creek in the western district—bigger than the Castlereagh River.

Diversion.

7782. Could any quantity of the water of the Macquarie be diverted into Duck Creek by a small cutting? Not into Duck Creek, which takes out of the Macquarie at a very high level, 12 miles below Warren. The Gunningba Creek is the easiest outlet for the Macquarie water.

7783. Would it be necessary to dam the water of the Macquarie? You would have to dam it to get it a sufficient height. If you dam back 6 feet of a head it would be sufficient, I think, from what I remember of the ground.

Permanent supply.

7784. Would that produce permanent water in Duck Creek? As long as the Macquarie ran; but it is not very much, you know; it has stopped several times within the last twelve months.

Natural depressions.

7785. Do you know of any natural depressions in the neighbourhood of that country where water from the Macquarie could be stored in times of flood? I know of none except the channels of the creeks—the country is too flat.

Soil.

7786. Do dams stand well on Duck Creek? Yes; the soil is fine clay.

By-washes.

7787. Do they have by-washes? You must have them; we have tried overshot dams, but we can do nothing with them.

Stability of dams.

7788. How do the dams stand? If you provide a good natural by-wash running a sufficient length before it joins the main stream again a dam will stand for years; I have two a few miles from here that have stood for years.

7789. Have you to take care that they do not cut? You cannot do anything in that way.

7790. Do they cut when the creek is running? Not if you provide a sufficient slope—they fall away with a very small slope. That is, supposing I provide a get-away or by-wash of a mile in length the fall in that would be more than 3 feet. There is so little current, and there is consequently very little scour. The natural surface is very difficult to dealt with, being sugary and soft, and if you are not careful you cannot do anything with the by-wash. My experience is—provide natural by-washes; do not attempt to make them, or you will throw away thousands of pounds if you do.

Current and scour.

The Bogan.

7791. You are well acquainted with the Bogan River? I am.

Dams.

7792. Can you give us any particulars of dams made across that river? Yes; I know nearly every dam from here 80 or 90 miles downwards. The first dam you come to is across the river, between Mr. Aaron's run and my brother's run, about 10 miles from here. It has a big sheet of water in it now—I was looking at it this morning as I came along. It backs water about 4 miles up the stream. The Bogan there is very insignificant; it varies very much in its depth and size.

7793. *Mr. Targett.*] Is the water at that dam permanent? Yes, it has never been dry.

Mr. T. L. Richardson. 28 May, 1885.

7794. *President.*] What other dams do you know? There was another dam about 3 miles below the first, but the get-away was too short, and the water formed another creek. It stood, however, about seven years. The next dam is what I always call the Big Dam, between my brother's two runs. That stood for eight years, until during a rise in the river twelve months ago the water ate through it. I wish to explain, with reference to earthen dams, that during long droughts, when the water has gone down very low in the dam, the bank becomes very dry and cracks all through, and we cannot always be attending to it, so that the first rush of water eats through the crack, and you come twelve or fourteen hours afterwards and find your dam gone. If any one were there to puddle up the creek when it occurred the dam would be saved. That dam was repaired shortly after, and is now full of water, which is backed up about 5 miles. The dam was repaired at a very slight cost—about £100. It is about 21 miles from here. It is a splendid natural get-away which goes out miles through the bush and joins the stream further down, forming a great natural cowal. It is the finest natural get-away on the Bogan River. The next dam is 26 miles from here, and is also between the same two runs of my brother's. It is as full as it can hold, right up to the banks; I suppose there is about 16 feet of water at the dam head. The water is backed up by the foot to the other dam, and the water is swimmable all the way from the one dam to the other. They are nearly 4 miles apart, and you cannot cross anywhere between them without swimming. Big dam.

7795. *Mr. Targett.*] What is the difference in the levels? I cannot tell—I can only make a rough guess. I should think there is a fall of 10 or 11 feet in the 4 miles, and that would make, as I said before, a fall of about 3 feet in the mile. There are no other dams until we get 70 miles from Nyngan, owing to the false economy of my neighbours, who will not pay a share of the cost of making a dam so as to fill Duck Creek. The river itself does not require it—it has big banks and permanent holes. Then there is a dam between my holding and Mr. Kyter's; it has a very deep natural get-away, but does not slope back more than 5 feet of a head of water, because the natural get-away is so very deep. There is another large dam which I have been two years in erecting, but it got carried away in the last flood before I had it finished. There is another dam lately erected on Mr. Hall's Nidgery run; that I believe is full of water at the present time. I believe there are none again until you get below Gongolgan, on to Mr. Randle's run. That is as far as I know. Fall. Dams.

7796. *President.*] Is the soil on the Bogan where these dams are made of the same sugary character as that you described as being on the Duck Creek? Yes. Soil.

7797. Is the ground along the banks good holding ground for water? Very good; most of the ground is not sugary—it is a good clay.

7798. But the ground that you say melts away if you attempt to open a channel, that I suppose is sugary? It is not a solid clay, but it is clay that will wash away with the scour of water; it is clay mixed with loam and other material.

7799. But there is no perceptible loss of water by soakage? Yes, there is; the greater the head of water, the greater the loss by soakage. The part of the bank that is above the natural line of water goes very quickly. When you first stop a dam full the water will go down nearly 3 feet before it comes to a standing level. Soakage.

7800. Supposing the country in the neighbourhood of the dam were used for watering sheep, would not the sheep puddle it sufficiently by their treading to prevent the loss? It would to some extent, but it would not effectually stop the soakage, as the soakage takes place before the ordinary head of water—when the water is up to the top of the dam.

7801. Is the soakage principally in the banks or in the dam? It is in the bank, not in the dam.

7802. Then according to that, it is scarcely wise to attempt to raise water above a certain level? The water must go by its natural get-away; we stop it as much as we can.

7803. Supposing the water could be kept up to a certain point close to the top of the dam and not materially lessen, the soakage would cease? It is not possible.

7804. You said just now that if you filled the dam beyond a certain point which is the ordinary head of water, there would be great soakage? Yes.

7805. But if you made the ordinary head of water lower, still the soakage would take place between the two points? No, I do not say that it would take place in the same proportion, but there would still be some; perhaps it would be only one-third of what it would be at a higher level.

7806. What is the cost of erecting those dams across the Bogan? They are not very costly. Of course it all depends on the size of the stream. The cost is generally from £250 to £500. The dam I have that carried away cost from £700 to £800, and it is not complete yet; but then I could not find a natural get-away and I had to make big wings to throw the water into a gully below. That is what made the extra cost. I have made a dam across a big stream for £300 which stood for years. Cost of dams.

7807. Do you think it would be a wise plan to erect dams on the Bogan wherever facilities offer for doing so, and to store as much water as possible in the bed of the river? I should most certainly say so; there is no other way of conserving water. Storage by dams.

7808. Do you find the landowners and others living below the dams object to the dams being placed across the river? I do not, excepting those miserable, parsimonious men who object to erect a dam themselves. No man objects unless he objects to pay his share. The mere local catchment between one dam and another will give enough water, without saying anything about floods.

7809. Does the erection of these dams across the river seriously affect the flow of water down the river in ordinary times? Well, every dam has to be filled before the water can run down. Supposing you had no other means of filling the dams but the floods which come down the stream—which is not the case, because the local rains give you a good supply—I think then it would be very objectionable; the men at the head of the Bogan would get all the water. But that has not been our experience; we always find that we get all the water we want without the river running through at all. Flow in river.

7810. Do you think it would be wise to frame legislation to deal with the question of obstructing the water, and giving power to either corporate bodies or the Government to deal in a broad and practical way with the whole subject? I certainly think so. I think the question should be dealt with—that is, the question of conserving water by means of dams. Legislation.

7811. What is the nature of the floods in the Bogan—are they rapid or sluggish? They are sluggish. Floods.

7812. And do you find that when they come down there is a large amount of silt deposited? No, the only silt deposited that might injure the stream is immediately below the big dam; it is the silt of the scour of the by-washes. Silt.

7813. But you have not found the river-bed above the dams to silt up? I think it does a little.

Mr. T. L. Richardson. 28 May, 1885.

7814. But not to a damaging extent? Not to a damaging extent. Unquestionably they silt up, because the water is full of mud which settles.

7815. But do you know of any appreciable silt in your dams and the dams you are acquainted with on the Bogan? It is about 6 inches in seven years for a mile above the dam, decreasing beyond that.

Width of floods.

7816. Which amounts to about 1 inch a year? Yes.

7817. Does the flood-water extend out from the bed of the Bogan at flood-time? Yes; when you get 60 miles below Nyngan the Bogan breaks out on both sides of my country and goes 3 or 4 miles out into cowals or natural watercourses. I have known the Duck Creek to do the same in high floods.

Effect of floods.

7818. And when the Bogan breaks out like that, is the effect upon the land as good as that of manure? Undoubtedly it enriches it very much.

Soil.

7819. Is the soil along the Bogan and towards the Macquarie good prolific soil? It is very rich soil, provided it has a good season and plenty of moisture.

7820. Do you consider it soil on which almost anything could be grown? I think it is soil that would grow anything.

Irrigation.

7821. Have you tried to irrigate to any extent? No.

7822. Do you know any case in which people have irrigated on the Bogan, such as gardens? No.

7823. Is it your opinion that if there was sufficient water in the Bogan or stored in such a way that it could be obtained for irrigation on a limited scale the landowners along the river would avail themselves of it? I do not think so; I think it would be only on a very limited scale that you could use it, because we never can store more than enough to last through a severe drought without taking anything out of it.

7824. But supposing the water was there in an unlimited supply, would the people avail themselves of it for growing produce and storing hay for their stock? I could not say.

Farmers.

7825. I suppose there are not many farmers in this district? There are none.

7826. Would many small holders of land resort to farming if they had water for irrigation? It is hard to say what people will do; if one man starts, he may set an example which his neighbours will copy.

Evaporation.

7827. Have you any idea or any practical experience of what the evaporation on the water surface is? No, I can only speak of evaporation combined with soakage—that is, the actual loss.

7828. What experience have you had in reference to that? For some years I had a very large body of water stored in a dam on Duck Creek. I used to raise a million gallons of water a day with a centrifugal pump, and let it run away; but I found that the water appeared to go as fast when I was not pumping as when I was pumping a million gallons a day.

7829. What size was the sheet of water? It was 18 feet deep at the dam head, and went back for 5 miles.

7830. From that you could not give the Commission any detailed account of the evaporation? Not of the evaporation. I consider that the evaporation was about the same as the soakage. After the water had got down to the standing level I thought as much went by evaporation as by soakage. At first I used to hold back a good head of water so that I could raise the water without much difficulty, because, in using the centrifugal pumps, if you have to lift the water high you cannot raise nearly so much as when you have to raise it a less height. By pumping up a great head of water I could throw 600 gallons a minute more.

Distribution.

7831. From your experience of the country between the Macquarie and the Bogan, do you think it possible to dam more rivers and raise the water so as to distribute a portion over the country lying between? I do not think so. I think all you can stop in the Bogan would be otherwise required; it would not do to take it away for other purposes.

7832. Do you think the same with regard to the Macquarie? No, because it is nearly always running; the Bogan is very different.

7833. If the water could be stopped in the Macquarie, is the country flat enough and low enough to admit of the water being thrown over the surface in a great many places between? From a certain distance below Dubbo it is flat.

7834. And once you get the water to a certain height you could distribute it by gravitation? You could. There would be no trouble so long as you went up stream—not down stream.

7835. I mean going from the Macquarie towards the Bogan? Oh, I think so—it is all about one level.

Wells.

7836. Do you know of many wells sunk in this part of the country? No, very few. I sank one out on the West Bogan country about twenty years ago.

7837. With what result? I got brackish water; I did not go on with the well.

7838. Do you water all your stock here from dams? Dams and tanks; no wells.

7839. Do you know of any artesian water having been found between this and the Darling? No, I never heard of a drop of fresh water being obtained between here and the Darling fit for drinking; perhaps if you went to artesian deposits you might get it down about 200 or 300 feet; there is none fit to drink.

Hay.

7840. Do you know of any instance here where squatters and others are cutting natural grasses for hay? I know of only one instance; my brother just below here has about 100 tons cut.

Cost.

7841. Have you any idea what it cost him a ton to cut it? It cost him £1 per ton; his manager told me this, knowing that he had worked in the most economical way possible.

7842. Is he intending to cut any quantity for the purpose of storing? No, he does not think he may want that for about three years.

7843. *Mr. M'Mordie.*] Do you know the country west of the Bogan River and north of the Lachlan? Down to Cobar I do, but not south of that.

Diversion from the Bogan.

7844. From your knowledge of the physical features of the country, would it, in your opinion, be possible to divert water from any point of the Bogan to any considerable distance in the country in a westerly or north-westerly direction? I think it would be quite impossible, because the country rises; as soon as you get 10 miles out anywhere on the west side of the Bogan you get on to ridges which rise as you go further westward; I should think the country in the middle is 300 feet above the level of the Bogan.

7845. Does that difficulty get greater or less as you go further up the Bogan? I think it gets greater; that is to say, I think the country of the Upper Bogan towards the Lachlan becomes more hilly as you get away from the river.

Elevation of country.

7846. *President.*] Do you think the country between this and Nymagee is higher than the Bogan at Obley? No, I do not think that; it gets gradually higher; I have never been out to Nymagee.

7847. Is the other country up about Bolgandramine equally high with the country between the Bogan and south of Cobar? I think it is higher; I should think it is 600 feet at Nymagee, and 300 feet at Cobar.

Mr. T. L. Richardson. 28 May, 1885.

7848. Is the country between the Bogan above Nyngan and the Lachlan fairly high and ridgy country? Yes, judging from what I have seen of it; I have not seen much of that country.

7849. Is there much or little wind in this part of the country as a rule? There is a great deal of wind, especially in summer. Wind.

7850. Is there wind enough to drive windmills? Yes, there is; but of course there are many days when you get no wind at all; you might, I should say, reckon one day in every two, or perhaps one in every three.

Water rate.

7851. If a scheme were adopted to divert a portion of the Macquarie water into the Duck, Gunningba, and Mara Creeks, at a moderate cost, do you think the landowners benefited thereby would be willing to contribute towards the cost in the shape of a rate? I do not think so, but I may be wrong; squatters as a rule have always had to help themselves, and if they think a thing is worth doing they think it is worth while to do it on their own account.

7852. *Mr. M'Mordie.*] Even without security of tenure? Oh, they chance that; they would do a great deal more if they had security of tenure, no doubt.

Supplying dry country.

7853. Can you make any suggestions as to the means of supplying the dry country between the Darling, Bogan, and Lachlan, with water? None beyond the means we employ now, namely, dams and tanks.

7854. That is, local tanks? Yes.

7855. Is the country you have just spoken of good wheat-producing country? Yes.

The Rev. J. Milne Curran, F.G.S., called in and examined :—

Rev. J. M. Curran. 28 May, 1885.

7856. *President.*] Have you resided any length of time in this part of the country? Yes, for some years; not exactly in Nyngan; I have been travelling over the district for some time past.

7857. Generally everywhere? Generally everywhere in the inland parts of New South Wales.

7858. Have you made a special study of the geology of this part of the country? Yes, I have always made use of any opportunities I have had for observing facts connected with geology, also the water supply of the district.

Water supply.

7859. And what has been the result of your observations in reference to the water supply of the district? I think it is better that I should give an outline of what my observations have resulted in. I will speak first about the surface water, and then give what evidence I have about the underground water. My evidence refers principally to the underground water supply, and what I have to say with regard to surface water is simply the result of observations I have made during the time I have been in the district. In the first place, with regard to the surface water, I think that if the country about here could be irrigated that, as far as soil is concerned, it would grow anything, but I think that a good deal that has been said and written about irrigating this inland country has been the result of comparisons made with other countries where the physical conditions are different. A great deal has been made of the example of India, but we have no Ganges here, and I think that to talk of cutting canals from the Macquarie or Bogan to irrigate the country on any grand scale is idle—not that the canals would be impossible, but because we have not sufficient water in the rivers. The Macquarie has been dry for months past, and the Bogan only flows a few weeks during the whole year; but if cutting of canals to irrigate the country would succeed anywhere I should think that it would succeed about Wellington, as the fall of the river is more per mile there than it is anywhere lower down. But with regard to surface water, I think that a good deal could be done by making dams on natural depressions so as to store flood-waters. With regard to the constructions of dams I cannot give any evidence, not having had any experience.

Surface water.

Storage of flood-waters.

Irrigation.

7860. If it could be proved that the rainfall in the eastern and hilly part of the country is sufficient if conserved to irrigate to even a limited extent, and if the water could be stored in natural basins at the heads of the rivers, do not you think a great deal of good could be done in carrying water by canals and irrigating various parts of the low-lying portions of the Colony? I think so, but the most we could do would be on a small scale compared with the country which requires to be irrigated.

California.

7861. Do you know that the rainfall in some parts of California is less by a great deal than the rainfall in Australia, and yet that they are carrying on irrigation works there on a gigantic scale? But I understand that the canals always come from running rivers. My deductions about irrigation are taken principally from India. I do not think much could be done in that way. In the first place, if we had magnificent catchments at the heads of the rivers, the rivers do not flow continually enough, as far as my experience goes.

7862. Supposing that the flood-waters of the Macquarie were conserved at the heads in the large basins which are there and the flow from the river was kept constant from the reservoirs, do not you think that a great deal might be done in the way of irrigation? I think so, but I have no faith in the amount of water that comes down the river to keep the dams supplied.

7863. That, you will allow, is a matter of calculation between the rainfall and the watershed and the soakage and the evaporation? Yes.

Evaporation.

7864. Have you had any experience of the evaporation which takes place here? No. I am inclined to think that it would be far more than is calculated by Mr. Russell, on account of the prevalence of hot winds. With regard to the underground supply, I take it for granted that the rainfall is far in excess of what is accounted for by evaporation or the outflow of the rivers or by soakage, and of course from the geological point of view I want to try to account for the water that disappears. I think that a glance at the geological history of these great plains will explain this in a great measure. The diagram which I produce is an enlargement of a plate prepared for the Linnean Society of New South Wales. Vol. X. (*Appendix Z.*) A B would represent the fall of the Macquarie before the plains were deposited, for I take the plains to be an alluvial deposit, and so the work of the rivers.

Underground supply.

Geological history.

7865. The whole plain country? The whole plain country.

7866. North and south? North and south. When I speak of the plain country, I should say that no one theory respecting the underground water supply will apply to all the interior, because the physical conditions are different. By the interior of New South Wales I mean all the country north of the 33rd parallel and west of Dubbo. So different are the physical features throughout that country that no one theory is adequate to account for the underground water supply. In that country I distinguished three districts—the plain districts, what I call the tertiary plains or the Merri Merri country, coloured green on the geological map of the Government. The

Rev. J. M. Curran. 28 May, 1885.

next division is the Silurio-Devonian country or the Cobar-Girilambone country. I call them by those latter names because the country around those places is typical of the whole area. The third district comprises the Warrego or cretaceous country. In discussing the underground water supply we have to consider these three districts separately. With regard to the underground water supply on the plains, I think the geological history of the formation of the plains will explain where the water goes to. AB will represent the fall of the Macquarie before the plains were deposited. All those plains are alluvial. The first proof of that is that the material of the plains at the greatest depth known is the same as the deposit of the river at the present time, and we find at various depths shells of different species that now inhabit the Macquarie. It may seem a vast amount of work to attribute to a few rivers, but it is not without parallel in other parts of the world. All this material brought down represents the amount of denudation in the upper valleys of the river, just as railway contractors when they cut down a hill use the material to fill up a valley. AB represents the original fall of the river. As the plains were deposited the river had to take levels as at C.D and E, while at A, say at Wellington, the level of the river is practically unaltered, or, if anything, is eroded, so that we have as the plains were formed rivers on different horizons; and the remarkable part of this is, that all this must be connected with the present river at some one point. This will explain to a great extent what becomes of the floods that never come down the river, as a flood coming down at A has to get away at many places, and all those underground channels must be filled before the water can flow on the present surface. It might be objected to this that, instead of having various channels, we would have one great river deposit under the present channel. This would be altogether at variance with the way in which we see the river working at the present time. If every flood that came down deposited detrital matter to an equal extent over the whole of the plains then the river would never leave its bed, because when the river bed was raised the plains would be raised to an equal extent. But we find that the heaviest deposits are always on the banks of the river, so that the river and its bed rise above the level of the surrounding plains until at some time it breaks away and forms a new channel, so that we have old rivers beds not only at different levels or different horizons but also over separate areas.

Alluvial plains.

Underground channels.

7867. Then, according to your theory, the water that falls at the head of the river and is not accounted for by evaporation or outflow, permeates through these various channels? Yes, which channels are on different levels and over different areas.

Storage at heads.

7868. Then, allowing that to be the case, do not you think the best thing which could be done in the first instance is to store as much of the rain-water at the head of the river as possible, and prevent it getting away into those underground channels? I think it would be a good idea if practicable.

7869. But your theory is, that if you take the quantity of water that flows at a certain point in the river you will find, by taking the water further down on the plains, that there is a loss of water somewhere? Not all over the country—only in the country I am now discussing; for instance, we find no loss between the Fish River and Bathurst; it is only when we come on to the plains that we find a loss, and when we should expect the underground channels.

7870. Then if the water were stored after it came to Bathurst, or at any point above that where the plains encroach on the high land, the water would be prevented from going through the underground strata described in the diagram, and could be utilized on the surface? Most certainly.

Loss of water.

7871. Can you give the Commission any practical experience from your own observation of the loss of water in that way? Not exact measurements, but in travelling down the Macquarie I found the river flowing at Dubbo while it was perfectly dry at Warren; that was about two months ago. I explained how, in the formation of the plains, these underground river beds were left under the present surface, and, luckily for us, not at any particular point but at different levels and over different areas. I want to put particular stress on that point. If the present country were covered to a depth of 200 feet with an impervious layer of clay and you sank a well (say) over the present river Macquarie, directly you struck the drift in the present river you would get a supply of water, and it is a remarkable fact that in every well which has been sunk on these plains the water has always been in river drift, and when they do not find river drift they don't get water. Imagine this 200 feet of impervious clay over the present level of the country. If a well were put down at a place called the Macquarie Cataract, at Rocky Point, we should have an artesian well. If through this impervious layer a shaft were put down the water would rise in the shaft, and we should have an artesian supply, for this reason: AB in diagram 2 will represent the present Macquarie; AC will represent our imaginary deposit of 200 feet. At point F, the present cataract of the Macquarie, there is a bar of rock across the river. If this deposit of clay were placed over the present level the water could not get away over this rocky bar, but would keep it back until it reached the point where the new surface touched the high lands, which would be about Wellington. Now the water not being able to get away at B, and the impervious layer of clay AC preventing its rising in that direction, if a bore were put down at D the water would rise in that bore exactly to the same height as A, where the new surface encroaches on the high lands. Something like this has taken place in the past and we have some examples of it; in fact there was a well sunk in Mullengudgeric, 16 miles from Nyngan, on the railway line, in which no water to speak of as tapped until at a depth of 64 feet they struck the old river drift, and immediately the water rose 40 feet. Then, with regard to the capability of rivers to do such work as laying down these plains, I think that whatever private opinion may be on the subject, very few geologists will dispute the fact. As a matter of fact, when a flood does come down it will always leave a deposit of from 2 to 3 inches over the plains, particularly over the banks of the river, and I have seen fences which were erected within the memory of people now living covered to the second rail by the deposit left by flood-waters. A resident of Narramine, Mr. O'Neill, informed me of a fact which is in keeping with my statement. He said that when it rains about Dubbo the water rises in his well before the floods come down the Macquarie, his well of course being sunk on one of these old river-beds. Now, with regard to the Cobar-Girilambone country, all through that district, as far as I have seen, the rock is never very far from the surface.

Artesian supply.

Cobar-Girilambone country.

Formation.

7872. What is the rock? All silurian and Devonian slates, schists, and limestones; and, from a geological point of view, we have every reason to think that water ought to be got in many places in this area in wells, particularly in the Devonian country. I have noticed that in very dry times in some of the Cobar-Girilambone country the creeks hold a great deal of water, which I cannot say is water flowing underground, but the sand holds a great deal of water at many points. I want to draw the attention of the Commission to an easy means of getting water in country of that description from the sand-beds. The information may be found in an article on Abyssinian tube wells published in the transactions of the Royal Society

Rev. J. M. Curran.

28 May, 1885.

Society of Victoria, vol. 22. With regard to the Warrego or cretaceous country, I cannot speak from personal knowledge, but we know enough of the geology of the cretaceous rocks to expect to find artesian water in that district.

Artesian wells.

7873. Do you know if any artesian wells have been found south of the Darling in the country you first described? Yes, many, for instance at Mullengudgeric.

Rise.

7874. Do you know of any case where the water has flowed over the surface? No, and in accordance with the diagram it would be hardly likely that it should occur, particularly when we consider the nature of the strata the water has to rise through. The further down you get along the rivers, the more probable it is that artesian water will rise above the surface. I think that over all areas the one great principle which was recommended to the digger in searching for gold should apply, viz., that you should secure all on the surface before you venture to look underground. With regard to the country between the Lower Lachlan and the Lower Darling, it resembles in all respects the country described as tertiary; and all that I have said with regard to the tertiary country applies to that, with this difference: that we should expect the deposits to be much deeper—that is, the deposits over the old river channels. In mesozoic times the South Australian country was raised more than 600 feet, and it is from that period that I date the origin of these plains, and it all depends upon what we do not know at present, viz., the exact extent and lie of the upheaval, what depth of alluvial deposits we should expect to find in this lower tertiary country. Of course all the facts and observations upon which I have come to the conclusions I have stated to you, I have not given, nor have I given any account of the wells that I know. I should be glad, however, if the Commission thought the information valuable, to throw it into proper form and submit it.

Country between Lower Lachlan and Lower Darling.

7875. In travelling about the district, did you find as a rule that the people you met took any interest in the question of water supply? None whatever; in the conservation of water of course they did, but in the underground supply I found that they took no interest whatever.

Fertility of soil.

7876. And do you find as a rule that the soil in the district is very rich and prolific? Yes, I think that the country is capable of growing anything, as far as the soil is concerned.

Population.

7877. Do you think that if there was a supply of water the country would carry a comparatively large population? Yes; water supply is the only question.

Water-rate.

7878. Do you think that there would be any objection to pay a reasonable rate for water if it could be obtained? On the contrary, I think they would be quite willing; I have heard more than one say that if they could get a stream of water flowing through a small paddock they would be independent.

Irrigation.

7879. Do you know of any gardens where irrigation has been carried on to a small extent? None, except the Chinese gardens.

Soil.

7880. Do you find their gardens here as prolific as in other parts? More so; I find that the soil is more prolific as you go from Bathurst to Nyngan, and requiring fewer artificial helps in the way of manure.

Local Trusts.

7881. Do you think that in the conservation of water on a large scale it would be wise to provide for the formation of districts to conduct their own works? I think that that is the only way by which practical results will ever be obtained—simply local government with regard to water conservation and supply.

Old river channels.

7882. *Mr. M'Mordie.*] At what stage of the geological process which you have described do you suppose that the old river channels were formed? The river at present is in its old age; the first channel was formed in the heyday of its youth. AB represents the river in the heyday of its youth; AE represents the present surface. The river channels to which I referred have been continuously in formation from the time the river occupied a level at B until it now occupies a level at C.

7883. Why in those particular drifts which you call the old river beds is the deposit different from the deposits above and below and on either side? Precisely for the same reason that we find the deposit in the channel of the present river different from the deposit on its banks.

7884. Is there any condition in process now between Bourke and Brewarrina which would at any future period constitute an old river channel? I cannot say that there is in the locality to which you refer, for this reason—that the time for those conditions is past in that part of the country.

7885. Do you suppose that those old river channels, where they exist, discharge water to the sea to any considerable extent? I cannot say; I know nothing about where the discharge goes to. That question has reference to a part of the country of which I have no practical knowledge.

Subterranean water.

7886. *President.*] Do you think that any of that subterranean water you speak of is found in the springs on either side of the Darling? I should think it probable, but I cannot speak from experience.

7887. You do not know of any instance where it reappears on the surface after disappearing? No, but I know of several instances where we have tapped it.

7888. And your supposition would be that it meanders away to some outlet, probably the sea? It is not necessary to suppose that it goes to the sea.

Subterranean lakes.

7889. There would be subterranean lakes now? A subterranean lake could hardly exist; there would be immense areas of pervious strata charged with water.

Subterranean current.

7890. Have you ever heard of an instance between the Murray and the sea in Victoria where water is found rushing rapidly from the direction of the Murray towards the sea? I have heard of instances occurring on the southern portions of the continent.

7891. Would you presume that that water made its way and discharged into the sea? I could hardly deduce anything more than the fact that it comes to the surface there.

7892. Do you know of any instance in this district where you have been able to detect the flow of the underground water? I think so; there is a well which was sunk by Mr. M'Lachlan, at Nevertire, in which I was told that there was a very decided flow to the north-west, which would be somewhat in keeping with the present drainage lines. One of the most remarkable facts in the history of continents is the permanence of drainage lines during long periods.

Wells.

7893. Was the water in that well found in drift? Yes; there is no exception. There is an apparent exception in the case of a well put down by Mr. John Kelly, at Myalmundy; but in that instance the well was in an old river drift, but consolidated so as to appear hard grit or conglomerate.

7894. Do you know how they tested the flow in the Nevertire well? A workman whom I questioned simply told me that the water all came in from one side. In keeping with the theory I have put before you as to what becomes of the waters which never come down the rivers, I have often noticed on the plains water flowing away from the creeks into great depressions, instead of flowing to the creeks, and then rushing

Rev. J. M. Curran. 28 May, 1885.

into holes and disappearing; that is evidently connected with the underground channels. I should like to make a suggestion with regard to the conservation of flood-waters. Noticing as we do that the ground on the banks of the rivers is higher, and noticing how far back the waters go from the Macquarie, I think it would be judicious to run lines of levels from the banks of the Macquarie into the back country, at various places between Dubbo and Warren.

Levels.

7895. That is, for the purpose of ascertaining how far water could be sent by gravitation? And also ascertaining where, by a small expenditure, great bodies of water could be prevented from returning to the river.

7896. Have you travelled much over the country between this and the south of Cobar? I go to Mount Hope and Nymagee.

Conservatio of surface water.

7897. Can you offer any suggestions which might be of service to the Commission in trying to supply that country with permanent water? I think, as I said before, that the first care ought to be to conserve the surface water in that country. I do not think that much could be done by bringing water either from the head of the Bogan or the Lachlan. I have taken levels by the aneroid, and I think that all the country about Nymagee, Cobar, and the south is considerably above the level of the plains where we are at present, and down to Coonamble and the Mara Creek.

7898. But it is much below the level of the country about Wellington? Yes.

7899. And you know of no means which are likely to be successful, except by storing surface water and trying to ascertain if there is any subterranean water? And, as I suggested, in the sandy creeks which are so very common, I think that the use of Abyssinian tube wells would be of great benefit; they are so

Abyssinian wells.

inexpensive and so easily managed. I have known instances of wells put down on what are called gilgais, and water has been struck in every instance. The wells were put down on Hermitage Plains, Mr. Mahony's run.

7900. Is there any other information you can give the Commission? Not that I am aware of at present; but in case I might be misunderstood in speaking of the underground waters, I want to call attention to one class of wells in this district to which my observations do not in any way apply; that is to what I call surface wells, which are sunk in lenticular masses of sand, which rest on clay, and the water is simply

Surface wells.

rain-water which the sand has absorbed. They give good water for a time only. We have some of them about 2 miles from here.

Mr. William Allison called in and examined:—

Mr. W. Allison. 28 May, 1885.

7901. *President.*] You live in the neighbourhood of Nyngan, do you not? Yes, I have lived here for five years.

7902. You have had considerable experience in squatting pursuits? Yes.

Dams.

7903. And in making tanks and dams and sinking wells over a large area of country? Yes.

7904. Do you find any difficulty in conserving water either in the Bogan River or in the dry creeks, or other creeks running into the Bogan, by means of earthen dams? No difficulty; the only thing necessary is to find a suitable place for making the dam; you cannot put a dam anywhere—you have to find a

By-wash.

suitable place, with a natural get-away or by-wash above the dam.

7905. And that is the most important feature to be noticed in selecting a site for a dam? It is the all-important feature to be noticed.

7906. Do you find the clay of such a nature as to stand the water well? Yes, in dams that I have. But the principal thing is to have a get-away sloping from the place where it starts to where it goes into the river again. It does not matter what the consistency of the clay is; if it has a steep fall into the river it is bound to go away.

Holding ground.

7907. And do you find all the clays and soils along the banks of the river good holding ground? Very good; of course when a new dam is put down the water invariably soaks at the surface.

Soakage.

7908. Does that lessen as the dam becomes older? Yes; still it is always a good deal, because the earth is left when the water soaks away, and when the dam is filled again it necessarily soaks away again.

7909. If the dam were kept fairly full that soakage would be still less? Yes.

7910. Do you know the Macquarie River very well? Not particularly.

Canals.

7911. Do you think any system could be adopted by which water could be carried in canals from the Macquarie or any other river in the neighbourhood, through the centre of the dry country lying between the Bogan and the Macquarie, by which these dams could be replenished in time of need? I doubt if there is any. There are some natural creeks where the Macquarie breaks out which might be used in that way, but it is doubtful if a channel could be made to carry the water across to the Bogan so as to be of any service. I think the natural run of water in the Bogan is sufficient for the dams, using it for stock only.

Storage.

7912. But do you not think the natural run in the Bogan and the loss of water in flood-time would allow you to store enough for irrigation purposes? Certainly not.

Irrigation.

7913. Do you think that if irrigation were attempted on any scale, water would have to be conserved at the head of the river for the purpose? I do not know the head of the Macquarie; at the head of the Bogan it could not.

Storage.

7914. If water were conserved at the head of the Macquarie, where natural facilities offer themselves, do you think that water could be diverted into the Bogan, if necessary? It would be impossible for me to say. I do not think any dam could be made at the head of the Macquarie to irrigate this country for any time.

7915. In speaking of "this country," do you mean the whole country? The country about the Bogan.

7916. Just in the vicinity of the river? Yes. I doubt if there would be enough for that, but not knowing the head of the Macquarie I could not say, though I should doubt it very much.

Diversion.

7917. Do you think that if the water could be diverted by means of a canal between the Macquarie and the Bogan it would be of service in replenishing dams, or be used for irrigation purposes on any scale at all? It is possible, if there was a sufficient flood of water. Speaking of the dams on the Bogan, I should like to

Nyngan dam

mention that the dam at Nyngan has been made in exact opposition to what I have pointed out as necessary. The surface of the earth has been cut away—a thing no practical man would do—and the dam has a steep fall into the river at the back, so nothing is more certain than that the dam must go at the first flood.

Mr. W. Allison. 28 May, 1885.

7918. By whom was it constructed? It was constructed by the Government. It is in a very bad place. It should have been about a mile below where there is a good natural get-away, and where I am certain that a dam which would stand fourteen or fifteen years could be made.

7919. But the dam having been made where it is, do you know of any means which could be adopted to preserve it? The only way I can possibly think of is that the channel should be stopped down there altogether, and be diverted and brought through culverts about half-way between the township and the river. That is the only possible chance of saving it, in my opinion. But by far the best plan would be to make a dam about a mile further down, where the natural get-away is.

7920. What height is this dam? I have no idea; it backs the water a distance of 5 or 6 miles. Back-water.

7921. Is there a good depth of water? 15 or 16 feet. Depth.

7922. Do you water the stock on your station principally from dams, tanks, or wells? Dams and tanks.

7923. Have you attempted to sink many wells? I have sunk one on the West Bogan about 240 feet deep, and I got brackish water suitable for stock, but entirely unsuitable for drinking. Wells. Quality of water.

7924. Did you try to sink lower? No; the water came in too fast. It rose 100 feet in the well in about a quarter of an hour. Rises.

7925. What is the size of the well? 6 feet by 4 feet. Size.

7926. Have you tried any other wells? I have tried on the East Bogan, and have invariably found salt water. Salt water.

7927. Have you tried on the East Bogan to go lower and get fresh water? Never.

7928. What strata do you sink through? Clay; occasionally coming upon small pebbles and gravel. Strata.

7929. What would you take the pebbles and gravel to be? Water-worn.

7930. Then, for practical purposes, sinking wells in this country has been a failure? Quite a failure, as far as my experience goes. I have got wells in sand drift within about 25 feet of the surface, but they invariably go dry after a little while. Supply.

7931. Have you any tanks back from the river on any creeks? I have tanks all over the creeks, usually in catchments; I have dams on the creek back from the Bogan. Tanks.

7932. Have you no difficulty in storing water there? No, there is plenty of water for stock.

7933. Have the seasons during the last year or two been very severe here? For the past four years they have been excessively severe. Seasons.

7934. Have you any idea of the proportion of stock which has been lost? It is very difficult to say; there have been losses every year. Loss of stock.

7935. Do you think the loss has been 50 per cent.? Quite that, I should think; for the past two years there has been no lambing here at all.

7936. Has that loss been wholly attributable to the want of feed? Entirely; I was never short of water. Want of feed.

7937. Could the loss have been prevented, to a certain extent, if water had been distributed more plentifully over the properties? I do not think it would have made the least difference—I had it well distributed.

7938. Do you think that if during these seasons you had had water for irrigation you could have grown any large quantity of fodder? I do not think so. Irrigation.

7939. Have you attempted irrigation at all? No, except in my garden by means of a windmill.

7940. With what result? The result was that the windmill could not keep the garden going. The wind was sufficient to keep the windmill going. Result.

7941. Then you had not the means of raising sufficient water for supplying the garden? No. The windmill was an ordinary Californian windmill. Windmill.

7942. What was the area of the garden? About half an acre. The ground used to crack, and through the cracks the water would run for three-quarters of an hour in a good stream. Area of garden

7943. Were you unable to grow vegetables? Yes, I had to give it up.

7944. Do you know of any instance where irrigation on a small scale has been attempted? No, I do not.

7945. With good seasons, does the soil appear to be rich and prolific? Yes. Soil.

7946. Have you attempted in any way to store hay from natural grasses? Not this year; this is the only year there has been a chance of doing it. Storage of hay.

7947. Do you think it could be done to any extent? It might be done, if it could be done to a sufficient extent to keep a number of stock.

7948. Have you ever had any experience as to what quantity of hay would keep sheep? No, I have not had any personal experience.

7949. Have you any idea? No; it would be too much like a guess.

7950. Do you know what the cost of collecting bush hay is? I have heard, but I do not know from personal experience.

7951. Do you know what is the cost of growing artificial hay? No, I have never grown hay.

7952. Have you had any experience of evaporation? No, not scientifically in any way. Evaporation.

7953. But practically? Practically I have, but I cannot give you any figures.

7954. What observations have you made? I am afraid I cannot give you any actual instances in which I have noticed it for any length of time.

7955. Have you not noticed the apparent evaporation from tanks and wells? Yes, but I have not noticed it for any length of time. I did keep a record once on a station near Cobar of the way the water in the tanks went down every week, and we reckoned that the evaporation in the middle of the summer during the hot winds was about 4 inches a week.

7956. That would be 8 feet during the summer months? Yes; of course in the winter-time there was no evaporation to speak of.

7957. Do you think the country is of such a nature that if it were well supplied with water it would be capable of carrying a considerable population? The soil is good. Population.

7958. It would be entirely a question of water supply? Yes; there are some places where the soil is very barren and rotten, but on the other side of the Bogan it is good enough for anything. Water supply.

7959. Which do you consider the best soil in the district for cultivation? The red loamy soil. Soil.

7960. Is most of the East Bogan soil black soil? Yes; I do not think it is capable of growing good crops.

7961. Will you describe the difference in the timber on the East and West Bogan? The timber is not very different; there is not so much myall on the West Bogan; there is myall 20 miles up from here. Taking it upon the whole, there is not a very great deal of difference, but the timber is very much thicker on the West Bogan. Timber.

Mr. W. Allison. 28 May, 1885.

7962. Is there a marked division in the country made by the river? Yes, very marked, 5 or 10 miles from Nyngan.

7963. *Mr. Gipps.*] Do cray-fish or vermin of any kind affect the dams at all? I have not found them to affect mine.

Cray-fish.

7964. Have you heard of any instances in which they have? I have heard of instances of their making holes through the dams, but I have never seen any.

Mr. Alfred Chapman called in and examined :—

Mr. A. Chapman. 28 May, 1885.

7965. *President.*] Do you live in this district? I am living here just now, near Nyngan.

7966. Do you know the district pretty well? Not very well.

7967. Which part of the country do you know best? The country about the Macquarie.

7968. How far from here? 75 miles; about 15 miles above Warren.

Creeks.

7969. At or near the point where you live are there any watercourses breaking out from the Macquarie which carry water in flood-times? Yes; there are the Ging Ging, the Bauban, the Beleringa, and the Gunningba Creeks.

Direction.

7970. In which direction do those creeks run from the Macquarie? When they leave the Macquarie they are running towards the Bogan.

Flood.

7971. At what stage of the height of the river does the water flow into these creeks? It breaks over the banks.

7972. Would that be at an ordinary or at a high flood? At a high flood.

Waterholes.

7973. Do the creeks become dry? There are waterholes in them.

7974. Natural or artificial? Natural.

7975. Do they never become dry? Not that I have seen.

Weir.

7976. Do you think that by placing a weir across the Macquarie below the off-take of these creeks a supply of water could be diverted in ordinary floods? I think so.

7977. Without injury to the property-holders below? I think so.

7978. Would that give permanent water at all times in those creeks? Of course it would not keep them running.

7979. But would it make the numerous waterholes permanent? I think so.

Nature of country.

7980. What is the nature of the country about there? Plains—myall and salt-bush.

Soil.

7981. What is the soil like—is it soft? It is rather soft.

7982. Is it not a hard red clay? No; it is all made soil—made by the overflow of the rivers.

Irrigation.

7983. Have you ever had any experience of irrigation on a small scale? I have never seen it tried but once; that was in the Riverina, on M'Caughey's station.

7984. Was it carried out there on a fairly large scale? No, it was done simply to irrigate a horse-paddock.

7985. Was it successful? No.

7986. How long ago is it since you were there? Seven years.

7987. Are you not aware that Mr. M'Caughey has improved his irrigation since then? I have been there since. He is now bringing the water from the creek on the opposite side, to irrigate the gardens and grounds about the house.

7988. Do you know whether he irrigated any agricultural land last year? I do not know.

7989. You do not know that he irrigated a paddock of hay, and got 2 tons of hay to the acre, when his neighbours did not get any? I can quite understand that.

Macquarie flood-waters.

7990. Where does the water flow to when it breaks out of the Macquarie as you have described? It goes down the Beleringa and Gunningba Creeks, and runs in a direction north-west towards the Darling.

Country.

7991. Is the country sufficiently flat between the Macquarie, the Bogan, and the Darling to conduct water over it, if there were a sufficient supply? Yes.

Wells.

7992. Have you had any experience of well-sinking? Yes, we have put down eight different shafts on the Macquarie at Mullah, and we got water in two of them, at a depth in one of 140 feet, and in the other at 85 feet.

Quality. Supply.

7993. Was the water good? Yes; there was not a very great supply in either. The water in the 140 feet well was not sufficient to water stock, and we went on with the shaft to a depth of 350 feet without getting any water, and then we put a bore in for about 120 feet, sinking the total distance 470 feet, and still we got no water.

7994. Did you never sink it further? No.

Strata.

7995. What did you come to? A kind of hard cement.

Drift.

7996. Did you go through any drift? Yes, but there was no water in it. We found that kind of cement at the place where we tapped the water in the first instance. The water fizzed out something like water fizzing out of a bottle of soda-water.

Cost.

7997. *Mr. Gipps.*] What did the sinking of the well cost? I think for 220 feet we paid £1 a foot.

7998. And for the boring? I could hardly tell you—we had men employed by the week. We used an ordinary Tiffin auger.

7999. *President.*] Can you not give any idea of the cost of the boring? No, I can hardly tell.

Work per day.

8000. What distance a day did the men go? During the first part of the work 5 or 6 feet a day, afterwards less. We had great difficulty in boring, because the auger kept continually breaking.

8001. Did the boring cost more than the sinking? No, not so much.

8002. Even though it was at such a great depth? Yes.

Other wells.

8003. What other wells have you? We have put down five other wells, averaging from 80 to 120 feet. In one we got water, but it was very salt; in the others we got no water at all.

Supply.

8004. Did you not get a successful well? Yes, one at 85 feet. It watered 2,000 or 3,000 sheep. It was not very good water. We found it in drift; it rose in the shaft about 20 feet. The well was about 18 miles out from the river.

Source.

8005. Have you any idea as to where the source of the water is? I think it is in the bed of an old river.

Strata.

8006. What did you pass through? Clay and a kind of cement.

8007. Do you think you would be likely to succeed in getting an underground supply of water in that country if you sank deep enough? I do not think so. Mr. A. Chapman.
8008. For what reason did you abandon the shaft at 120 and 130 feet? We did not think we could get any water, after going on with the others to so great a depth. 28 May, 1885.
8009. Were they near the others? A few miles away.
8010. Do you know anything of the Macquarie Marshes? Not very much.
8011. Do you think all the creeks and rivers in this part of the country could be easily dammed across? I doubt if the Macquarie could be easily dammed, because the soil of the banks is of such a nature that it would be difficult to put up a dam which would hold; it is an alluvial black soil, which seems to melt with the water. Damming of rivers.
8012. Do you think that masonry overshot dams would be successful? I do not fancy so. Overshot dams.
8013. Have you any idea as to the best mode of storing water in any of these creeks? No, I have had no experience except of ordinary earthen dams.
8014. And these you think would not answer on the Macquarie? No, I do not think they would.
8015. Are there any natural bars across the Macquarie which would form foundations for dams? Yes, two or three. Bars.
8016. Is not the Macquarie dammed at any place? Not that I know of; there is a place near Narromine where the soil is a sort of conglomerate of clay. Dam at Narromine.
8017. Would that prevent the water from soaking through? Yes.
8018. Does that dam back a good deal of water? Yes.
8019. Does it rise near the surface on the banks, or does it simply crop out on the bottom of the river? It is about half-way up the banks.
8020. Then if an overshot dam were placed across the river, even going as high as this bar goes, would it raise the water in the river considerably? It would raise it some 6 feet. In connection with the putting of the water into the back country between the Macquarie and the Bogan, my idea all through has been that the best place is at Narromine—I think the river should be locked there. There is a cowal running through there into the back country, and it may be possible to put the water down that. It would water a large extent of country lying between the Bogan and the Macquarie. Cowal.
8021. Or it could be brought by a canal if a canal were constructed? Yes.
8022. And if water were taken from the river at that point, would it water a large area of what is at present dry country? Yes, it would.
8023. And good country? Yes.

Mr. Augustus Lyne called in and examined:—

8024. *President.*] You have resided at Nyngan for some years? About four years. Mr. A. Lyne.
8025. Have you seen the Bogan River in flood? No.
8026. Have you taken any notice of the dam across the Bogan at Nyngan? I have. 28 May, 1885.
8027. What is your opinion of it? I have never seen a flood here, but I believe that the dam will go the first flood we have. I have seen a little fresh that has passed over the by-wash and carried a great deal of it away. Dam at Nyngan.
8028. In the event of that dam going, would it leave the township of Nyngan without water? It would.
8029. Do you think there is an urgent necessity to put another dam below it or to repair it so that it will stand? No.
8030. Do you not think it is possible to repair it so that it will stand? I do not think so.
8031. Does it back any quantity of water at the present time? Yes, a great deal.
8032. And that water is permanent? Yes.
8033. Have you had any experience of irrigation here on a small scale? Yes; in a garden, by pumping water from the river by means of a windmill. The patch of ground was very small. Irrigation.
8034. And has the result been beneficial? Yes.
8035. And at times when the rest of the country is bare you are able to grow all kinds of vegetables? Yes, anything.
8036. Do you find grapes grow well here? Very well.
8037. Do you think irrigating the soil would produce vineyards to any extent? Yes. Vineyards.
8038. Do you think from your knowledge of this district that there is a sufficiently large extent of soil here to carry a considerable population if there were water to irrigate it? With water anything could be grown. Population.
8039. Do you think it would be desirable to create Water Trusts to conserve water all along the creeks, or should the matter be left to the Government to deal with? I think it would be better to leave the matter in the hands of the Government. Water Trusts.
8040. Why? Local Boards are very good, but they generally disagree, and on the whole I think it would be better to leave it to the Government.
8041. Would the people availing themselves of the water pay a rate to the Government? I fancy they would. Water rate.
8042. *Mr. Gipps.*] Do you not think a water supply for the town might be obtained from wells? I am sure it could not. Several wells have been sunk in the town, but the water obtained has always been salt. 250 feet is the depth of the lowest bore that has been put down close to Nyngan. Town supply. Wells.
8043. Have they bottomed on rock? No.
8044. What is the character of the strata? First, clay for 20 feet, then drift sand and layers of clay and drift sand. Strata.
8045. At what depth did they obtain the salt water? First at 75 feet. Depth.
8046. And it was not in sufficient quantities to prevent them from sinking further? No.
8047. Did they ever try boring? Yes, they bored the whole distance. Boring.
8048. And the sand was the cause of their not getting on faster with the work, and it eventually stopped them without their bottoming on any rock? Yes, without bottoming on any rock.
8049. Have they tried any wells near the river? One well was sunk in another part of the town, and a large supply of salt water was obtained. I sank a well close to the old bed of the river, and at 65 feet got fresh water, but not a large supply. Salt and fresh water.

FRIDAY,

FRIDAY, 29 MAY, 1885.

At Dubbo.

Present:—

MR. GIPPS, C.E., | MR. MURRAY, M.P.,
MR. LYNE, M.P., | MR. M'MORDIE, M.I.C.E.,
MR. TARGETT, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. William O'Neill called in and examined :—

Mr. W. O'Neill. 29 May, 1885.

8050. *President.*] Where do you reside? At Narramine.

8051. Have you resided there any length of time? About seven years, and on the Macquarie River over twenty-two years.

Floods. 8052. During that time have you seen any large floods in the Macquarie? Yes. In 1879 the water rose to within 4 feet of the top of the bank of the river. I have seen three floods—one in '66, one in '70, and one in '79.

8053. Did any of those floods overflow the banks of the river? Yes, to a considerable extent from Narramine down.

8054. Not above Narramine? Only just a short distance back.

Silt. 8055. Was the water at the time of flood very muddy? Yes, very muddy; in fact, the last flood left 4 inches of silt on the ground which it covered.

8056. Was that in the current or the back-water? In the back-water.

Dams. 8057. There are no dams across the Macquarie, are there? No.

Overflow. 8058. Have you ever seen the river overflow its banks anywhere near Narramine and the water run off in the direction of the Bogan? Yes; at Narramine, just about where I live. In 1866 I happened to be in Dubbo, and I was blocked by the flood until the river went down. When I went down the river I saw traces where the water had gone into Backwater Cowl and flowed away westward towards Dandaloo, on the Bogan; it also ran down towards Trangie, Timberabungie, and Buddah Lake.

Cowl. 8059. Was there any stream of water apparently flowing down the Cowl to Dandaloo? Yes, I believe the Cowl was full.

Size. 8060. About what size is the Cowl? I think about 100 feet across below Backwater; it is about 6 feet deep—in some places 12 feet.

8061. Would this Cowl afford great facilities for the storage of water in time of flood? Not below Backwater—it is too shallow.

Diversion from Macquarie. 8062. Do you think any means could be adopted to divert any portion of the Macquarie water by means of dams anywhere about Narramine? Yes. I may state that some time ago Mr. Cass asked me to supply him with information about the district as to its suitability for water conservation, and I wrote him a letter, which I believe he did me the honor to hand to the Commission. Subsequently, Mr. M'Kinney visited me at Narramine, and I took him to Rocky Point, on the Macquarie River, and also up the river

Old river bed. to Narramine, to what I call the Narramine Lake—a considerable depression which I think is the old bed of the Macquarie River. I produce a sketch of the Macquarie River from where Brummagem Creek goes

Rocky shelf. into it from the south side. Just below the junction of the river there is a rocky shelf, as shown on the sketch, consisting of hard granite.

8063. Does that extend across the river? No; it appears to me that the water has at one time run over that and made a cataract of it, but it has continually washed on to the north bank until it made a depression like that shown on the sketch produced, and marked A. There is about 10 feet of water in that, and the rock appears to shelve in right across the river. I measured the level of the top of the bar from the water and found it to be 18 feet. It is 3 chains across that rocky shelf to the south bank. What I would

Dam. suggest to the Commission is the erection of a dam on that rocky shelf.

Height. 8064. To what height? It will require to be 12 feet above the rock; that will give 30 feet above the present water-level.

Depth of water. 8065. If it were at that height, what would be the effect on the water above the dam? There would be 30 feet of water above.

Banks. 8066. Would that go out beyond the banks of the river? It would not flow out of the river; the banks are 53 feet high.

8067. Are the banks higher than the country a little way away from them? No, they are 3 or 4 feet lower than the country about where the water has never been known to flow. In 1879 the flood-water was 2 or 3 feet over the bank of the river at the place where I propose that the dam should be put.

Back water. 8068. If this dam which you suggest were made, would it back water up to such an extent that by a cutting it could be led out of the river above? Yes.

Diversion. 8069. And if that dam were made, at what point above could the water be diverted out of the river bed,

Cutting. and by what means? By means of a cutting (as shown on the sketch) from Brummogem Creek to Euromadan Lagoon; that would be a distance of about 250 yards.

8070. If water were conveyed into this lagoon, would it find its way back into the river unless stopped? What I propose is that the cuttings should be continued through the lagoon into Narramine Lake, a distance of about 3 miles.

Depth. 8071. What depth of cutting would there be in that 3 miles? It would average 9 or 10 feet.

8072. Is it country that could be easily excavated? Yes, it is all clay.

Narramine Lake. 8073. When the water got into Narramine Lake would you propose to dam that lake? I should propose to put a dam about 3½ miles from the top where the water comes in to the lake. The estimated capacity would be 4,500,000,000 gallons of water. If this suggestion of mine were carried out I estimate that the

Capacity. capacity of Narramine Lake would be about 4,500,000,000 gallons, while the quantity of water stored in the river above the dam would be 2⅓ billions above the weir; in Backwater Cowl ⅓ of a million between the upper and lower dams in the Cowl, and in what I call the crescent depression there would be 1,600,000,000 gallons more stored, making a total of 8,909,000,000 gallons of water.

Elevation. 8074. If this water were stored, would it be at a sufficient elevation to command the country lower down? Yes, it would flow by gravitation on to adjacent Crown Lands. I would also suggest the erection of a lower

dam

dam in Backwater Cowl, a mile from the first one, so as to drain water out of the crescent depression, and also that a cutting should be made above the first dam to let the water into the crescent depression, and a cutting made out of the crescent depression into the Backwater Cowl above the second dam, which would make an outlet to preserve the first dam and give a means of filling the Cowl between the two dams.

8075. Could not a succession of dams be made down the Cowl? Yes, a succession of dams could be made down the Cowl 3 or 4 miles further, securing at least 10 or 12 feet more water for 3 or 4 miles further down the Cowl. Succession of dams.

8076. And the whole of that water would be at such an elevation that it would command the plains country lower down? It would command the whole of the country lower down. Elevation.

8077. You have made an estimate of the cost of the whole of this work as described, providing for a concrete dam across the river, and the estimate you make is based on the prices now paid by squatters for similar work? Yes. For the price of the concrete per yard I am indebted to Mr. Moffatt of this town. Cost.

8078. And you make the total cost of the work suggested to be £24,350? Yes; a wooden weir on top of river dam 10 or 12 feet high would cost for 200 feet wide about £2,000 more.

8079. *Mr. M'Mordie.*] What is the concrete estimated at? £2 10s. per cubic yard; there are 4,003 yards. In addition to the concrete dam, I would suggest that there should be a wooden weir on top of the dam, with the piles set in the concrete. Wooden weir.

8080. Would it be permanent or movable? I have not attempted to give any opinion as to how it ought to be done, but it is necessary that there should be a movable weir on top of the concrete dam to regulate the flow of water down stream. The quantity of water estimated is not the quantity which would be dammed up by the concrete dam, but the other dam or weir on top of it. The water which would give the supply to the Narramine Lake and the other depressions would all be stored above the level of the concrete about 10 feet; that would contain an area of water 400 feet wide 10 feet deep and 15 miles long; the body of water below the top of concrete level is not calculated in my estimate of capacity.

8081. Do you think that if such a work as you propose were carried out, it would silt much from the stuff which comes down in flood-time? That is a matter upon which I would not like to offer an opinion, because we have no evidence anywhere to show that dams will silt up. Silting.

8082. But you have said that in one flood you noticed silt 4 inches thick on the land which had been covered by water? Yes, that was the sediment in the back-water or still water.

8083. *Mr. Gipps.*] Was that the result of one flood? Yes.

8084. How long did that flood last? I suppose not more than about five days.

8085. *President.*] Was that the back-water? Yes.

8086. *Mr. Targett.*] What was the nature of the silt? Fine sand; you may say mud.

8087. Would it damage pastoral or agricultural land? I should rather think it would improve it.

8088. *President.*] Do you think that the same thing as you suggest could be carried out at various points along the Macquarie? The Macquarie River dammed at intervals of 10 miles above and below Narramine on the rocky bars would hold enough water to irrigate some hundreds of thousands of acres, the greater portion of which could flow on to Crown Lands on either side of the western railway line from Narramine to Nyngan. Damming of the Macquarie.

8089. And by weiring the river down there, throwing a dam across, the same result as you have shown in your sketch would take place? Yes.

8090. Have you noticed any loss of water from the Macquarie channel at Narramine? No; it all goes back again; the ground seems to be very firm in that neighbourhood; there is, however, about 8,000,000 gallons loss daily below Rocky Point, which seems to be checked by the rock bars and sent towards Coonamble in the vicinity of the Monkey Scrub. Loss of water.

8091. And you think there is no loss from soakage? I do not think there is any soakage, except in respect to what I have stated.

8092. Have you a well at Narramine, a little way from the river? Yes. Well at Narramine.

8093. What depth is it? It is about 80 feet deep, and about 4 or 5 chains from the river. Depth.

8094. What did you sink through in getting water? The first 35 feet seemed to consist of layers of silt and mud, which had hardened into a red stiff clay, and after that layers of sand and gravel for about 35 or 40 feet more until the water was reached. I think it is nearly 40 feet below the river water at summer level. Strata.

8095. Do you think that what you passed through was deposit from the overflow of the river at various times? It looked like it.

8096. And is the water in the well river water? No, it has no local connection with it. Source of water.

8097. And where do you imagine is the source of the supply? I think it is about Dubbo. I think it must come from near Dubbo, from the river strata or tertiary drift.

8098. Have you ever noticed that when the Macquarie comes down in a flood the water in your well is affected? No, it is not affected; but during the rains they had in Dubbo last summer and recently it was affected.

8099. But not by the rise and fall of the river? No.

8100. Then from that you would deduce that the watershed is somewhere about Dubbo, but is not the river? It is not the river down there, certainly.

8101. Did the water rise much in the well after the rain? Yes, it rose 2 feet during the wet season in Dubbo last year. Rise.

8102. You have another well? Yes, half a mile away from the last—further out from the river. Other well.

8103. What did you sink through there? Drift somewhat similar to the material in the well near the river; it appears to be the same layer of water. Strata.

8104. And at what depth? About 90 feet. Depth.

8105. Did you get a good supply of water? No, I only went about 3 feet in; it still keeps at the same. Supply.

8106. Is that well affected in the same manner as the other well by rains at Dubbo? I do not think so; I hardly know where the water comes from in that drift; it may come from further south or from the direction of Harvey's Range. Source.

8107. But do you think it has any connection with the river? Not down there.

8108. Have you a good supply of water in the well first described? Yes, and the water is good in both wells. Quality.

8109. Have you tried cultivation at all? Yes. Cultivation.

Mr. W. O'Neill. 29 May, 1885.

8110. To what extent? I have about 60 or 70 acres under cultivation.
8111. Do you usually get a good crop? Pretty fair.
8112. Have you suffered from the dry seasons? Well, I could always grow a ton of hay to the acre at Narramine.
8113. Did you ever try the effect of irrigation? No.

Soil.

8114. Is the soil good in your neighbourhood? Very good—good enough to grow anything.

Population.

8115. If there was sufficient water for irrigation purposes, do you think the soil is capable of carrying a considerable population? Yes, I do.
8116. Have you ever tried to raise water by means of a windmill? No, the water is too low in my wells.

Sheep feeding.

8117. Have you ever fed sheep on hay? I have fed them on straw, not on hay.
8118. And you have no idea what quantity of hay it takes to support a sheep? Last year I bought a considerable amount of straw and gave it to the sheep. I allowanced them to 6 ounces a day on the average; some ate more and some less.
8119. Was that all the food they had? That is all except what little leaves and scrub they could pick up. With 6 ounces of straw and 2 ounces of green feed, sheep would live through our droughts if not too heavily stocked.
8120. Did that keep them in fair condition? No, the feed was too dry; I find that dry feed does not do for sheep.

Trusts.

8121. Do you think that such a scheme as you have suggested or sketched would be better carried out by Water Trusts, the people doing the work themselves and borrowing the money from the Government, or that the Government should undertake the work. I think that the Government would carry out the work better themselves; they have a better command of professional men; the sale of the land would pay more than the cost twice over.

Repayment of loan.

8122. How would you suggest that the Government should be repaid? The quantity of water proposed to be conserved I estimate would irrigate about 20,000 acres, giving the water at the rate of 3 inches seven times in the year. The whole of the land included in this area of 20,000 acres is good, and may or may not be open to selection when the runs are divided. I would suggest to the Commission that they should lose no time in getting it reserved from sale.
8123. But the question I asked is, how should the Government be repaid—by the sale of the land, and supply the water for nothing? No; the Government could complete the works, and the sale of the land would more than repay the cost of them twice over.

Water rate.

8124. And after that not charge any rate? Yes, charge a rate commensurate with a fair interest on the outlay.
8125. Do you think that the people who would use the water would be prepared to pay a fair sum for such water as they used? I am certain of it.
8126. How much do you think they would pay per acre? I would be glad to pay £1 an acre if I could get 3 inches of water three or four times a year on my land with our present rainfall.
8127. The land which would be irrigated adjoins the railway between Dubbo and Nevertire? Yes.

Settlement.

8128. Do you think that if the scheme which you propose were carried out it would induce settlement? Yes, I imagine it would very rapidly.

Evaporation.

8129. Have you had any experience of the evaporation from the surface of water? I have noticed that the evaporation in the locality I referred to is very little. Last summer in the midst of the drought I had a 2,000-yard tank in the cowl named. There were 1,500 sheep drinking water out of it all the time, and the loss by evaporation, drinking, and everything only amounted to 15 inches all last summer. There was no rain for about four months.
8130. What surface of water was there in the tank? 9 feet deep; I forget the width across. There was very little surface area; I think it was about 50 feet across—may be 100 feet.

Objections to works.

8131. If water were stored in the way you suggest, do you think the people further down the river would object to such a work being undertaken? The weir I propose on top of the concrete dam would regulate the flow of water so that it would make no difference to them as far as flood-waters were concerned or otherwise.
8132. Would any of the floods you have mentioned fill that depression? Yes; we have several freshes in winter-time, any one of which would fill it in thirty-six hours.

Soil.

8133. What kind of land is it which would be irrigated? It is alluvial soil—principally red chocolate soil.

Granite.

8134. Is there any other granite country near except this? There are granite rocks projecting out of the river side. The bar I have mentioned is the best site I know of.
8135. But the granite does not come to the surface of the soil? It rises above the surface to a considerable distance, but shelves off again.
8136. But away from the river? Below Narramine it is, as you may say, at the foot of the hills. Below Narramine there is very little rock of any kind.

Rainfall.

8137. What is the annual rainfall at Narramine? Last year I think it was 12 inches; I believe the average is 15 or 16 inches; it is only within the last three or four years that we have been taking any observations of rainfall at all.

Silt.

8138. *Mr. Murray.*] Do you think that much silting would take place in the Narramine Lake or in any other excavations made? I do not think so.

Building material.

8139. Is there good stone in the vicinity of the works proposed? It is all hard granite, and there is any quantity of river shingle for concrete purposes close by.
8140. Is there any stone but granite in the vicinity? I think there is; there is a kind of slate half a mile from there.

Loss of stock.

8141. Has the loss of stock been very great during the last four or five years? Yes.
8142. Do you think that a system of water conservation would have saved a great deal of that stock? Yes, because it would have enabled the stockowners to obtain some green feed; it is the constant dry pasture which kills most of the sheep, such as leaves, scrub, and dry stubble grass.
8143. Do you think that the pastoral tenants would avail themselves of the water supply for grass purposes? I do not think so; it would pay better to cultivate.

Artificial feed.

8144. And supply the stock with artificial feed? Yes.

Water rate.

8145. In cases where the land is alienated from the Crown, do you think that the owners would be satisfied to pay a fair water rate? Yes, I think so.

8146.

8146. And your impression, judging from what we have heard from you, is that water conservation would increase the prosperity of this district very much? Yes; I consider that if those works were completed you could establish 500 families on the locality I refer to, on from 10 to 40 acres of land each. Mr. W. O'Neill. 29 May, 1885.

8147. How much would the 20,000 acres you speak of be enhanced in value if made available for cultivation by a supply of water? If it was cut up into 10, 20, 30, and 40-acre blocks it would realize £5 and £6 per acre readily. Value of land.

8148. Then you think that 40 acres irrigated would support a family, and be worth as much as 2,000 acres are now? Yes, much more so.

8149. And you think it would be better for the Government to reserve the land and get the enhanced value after the water was laid on, than to sell it first and put on a water rate afterwards? They would have to provide water first before people would buy, but if there was water the Government could readily sell the land.

8150. What are the prevailing winds here in summer? Westerly. Winds.

8151. Are they continuous? Yes.

8152. Sufficient to allow the application of windmills to pumping? Yes, I think so, from shallow depths. Windmills.

Mr. Robert George Dalhunty called in and examined :—

8153. *President.*] Are you Inspector of Stock at Dubbo? Yes. Mr. R. G. Dalhunty. 29 May, 1885.

8154. Have you lived any time in this district? Yes, forty years.

8155. And you have had experience over the whole district? Yes.

8156. From the Castlereagh southward? Yes, I have been living at Dubbo the greater part of my life, but I have been all over the district, and all over the country pretty near.

8157. What is the nature of the country lying between the Castlereagh and the Bogan? Nearly all flat, black, porous plains. Parts of it between the Macquarie and the Bogan higher up are ridgy and consist of granite, but anywhere below Narromine the soil consists of black, porous plains, with belts of timber. Country.

8158. Is it level? Very level.

8159. And intersected by depressions and watercourses? Yes, cowls or gilgais as they call them. As you get lower down towards Warren there is almost a network of creeks overflowing from the Macquarie in times of flood. Cowls. Creeks.

8160. Is the Castlereagh a permanent river? No; but there is always a permanent supply of water in the sand a short distance down. The Castlereagh.

8161. But you have to sink in the sand for it? Yes.

8162. Are the floods heavy? Yes, I have seen very heavy floods. Floods.

8163. Do they cover any very large extent of country? Not very; they go out of the Castlereagh, but they do not go very far except in one or two places, where they fill the head of the Merri Merri Creek, and run for many miles through the back country. Merri Merri Creek.

8164. Do you know anything about the underground water westward from the Castlereagh? Yes, in what they call the Monkey, a bed of sand thickly timbered with pine scrub which extends for 50 or 60 miles, with an average width of half a mile. The Monkey.

8165. You can get water by sinking anywhere through it? Yes, at from 10 to 12 feet, and a good supply.

8166. But you do not know that it comes out of any river bed? No; I have an idea that it comes out of the Castlereagh near Coonambarabran, but you can see no signs of it there. Source.

8167. Your idea is that it goes underground and re-appears at the point named? Yes.

8168. *Mr. Targett.*] Is there any noticeable depression? Yes, in some places very marked. There are hard plains on each side, and it drops into white sand. In the middle of the sand bed there are large ridges in many places along the course of the sand. Depression.

8169. *President.*] But sinking anywhere you get water? Yes, according to the undulations of the surface.

8170. *Mr. Targett.*] Is there any noticeable current in the well? I think not; the water seems to come in all round the well. Current.

8171. *President.*] Is the water good? Yes; it is whitish, but it is very good. Quality of water.

8172. Does it rise in the wells at all? When first struck it rises 6 or 8 inches, but as you sink down it gets to a uniform level. Rise.

8173. Do you know of any other similar places in that country? I know of many places where the same water is got, in what they call Little Monkeys, which have no connection with the Big Monkey. There is a place called Back Tenandra, about 15 or 20 miles from Collie, a township on the Marthaguy Creek. Little Monkeys. Back Tenandra.

8174. Of what extent is that Monkey? About 4 or 5 miles long, and a quarter of a mile wide. There are innumerable wells there. In one drought there were fifty wells there, and half the stock of the country were camped round it. It is a totally dry country otherwise, but they got these wells, and there was plenty of grass. Wells.

8175. Has this Monkey any apparent connection with the large Monkey you have described? No, there does not appear to be any connection, but it is not far from it. Connection.

8176. Does it run in the same direction? Yes. Direction.

8177. Do you know of any others? The only other that I know of is the place between the Bogan and the Macquarie, and not very far from Nyngan. There were some wells sunk on a Monkey there, but they were much deeper, and the water was totally different, but it is the same sort of Monkey. Monkey near Nyngan.

8178. Do you know of any others? Down on Mr. Egan's run, below Mount Harris, on the east side of the Macquarie, there are some wells sunk in a Monkey. Near Mount Harris.

8179. Of a similar nature? Yes, and the same sort of water, and at about the same depth.

8180. Do you know of any others? No.

8181. Do you know of any places throughout your district where irrigation has been attempted at all? Yes; I saw it tried at Mr. Flood's, at Quambone, on the Merri Merri Creek. I saw about 40 acres of hay sown in the month of June, 1884, on poor soil, irrigated twice with a centrifugal pump; it yielded pretty nearly 5 tons to the acre. Irrigation. Yield.

8182. Whilst that was growing was there a bad season in the surrounding districts? Yes, and stock dying in all directions.

8183. How was the water distributed? The water was run first into galvanized iron troughs, then into drains about 3 feet wide and 8 inches deep. The drains ran all round the paddock, and there were cross-drains, and the water soaked from one drain into another. Distribution.

Mr. R. G. Dalhunty. 29 May, 1885.

Loss of stock. 8184. Do you know of any other instance? No, I never saw any other.
8185. During the time of the last few years of drought have you had serious losses of stock in your district? Yes, very heavy losses indeed.
8186. About what proportion do you suppose? I should think it must have been nearly 60 per cent.
8187. What did Mr. Flood use the hay for which he grew? He was breeding race-horses, and he used it for them.

Artificial fodder. 8188. Do you think that if the lessees as a rule adopted a system of agriculture and of irrigation they could grow any quantity of fodder to keep sheep alive during dry seasons? I think they could, but I do not think they would—it would not pay.
8189. But would they buy it if it were shown that it would prevent the losses that occur? No doubt they would use it largely for stud sheep or cattle. It would be a very poor thing to grow hay to feed some squatters' sheep, as some of them keep up to 180,000 sheep.

Cost. 8190. What do you estimate would be the cost of growing hay? The cost of growing it by ordinary means is about £1 per ton.
8191. And to that would have to be added the cost of water? Yes.

Natural depression. 8192. Do you know of any places in your district where large quantities of water could be conserved in natural depressions? No, I do not, except this back-water and the Buddah Lake, the place described by the previous witness (Mr. O'Neill), though he mentioned one place which I do not think much of—the Narramine Lake. Narramine Lake. I have seen it full of water one week, and only about 8 inches in it the next. The soil does not appear to hold—it is nearly always dry.

Damming of the Macquarie. 8193. Do you think it is possible to dam the Macquarie River at various points so as to conserve large quantities of water in the river bed? I think it would be a very expensive and very difficult undertaking, though I suppose it could be done.

Trusts. 8194. Do you think that works for the conservation of water should be carried out locally by Trusts created for the purpose, or by the Government? I think the Government would have to do it.
8195. And then charge a rate for the supply of water? My opinion is that it would be much better if it could be done by Trusts, but I am sure it never would be done.
8196. But if the Government were to carry out two or three schemes, to show that it could be done, do you think that then Trusts would be likely to take the matter up? They might; the people have been taught many things by Victorian enterprise, and I have no doubt that there would be plenty of money and enterprise if it were seen that it could be done.

Underground supply. 8197. Do you think that generally there is a plentiful supply of underground water over the lower parts of your district? I do not think so. I speak from experience of the wells which have been dug. People have gone enormous depths for water without obtaining it, and at other places have got a good supply at a comparatively shallow depth.

Narrow drifts. 8198. That would lead you to suppose that the water was running in narrow drifts? Yes, something of that sort I suppose.

Population. 8199. Do you think the country about here would carry a fair population if they could get water? I think so.

Creeks about Warren. 8200. *Mr. Targett.*] Do any of the creeks about Warren hold permanent water? Yes, nearly all the creeks below Warren hold very fairly, but the holes are not large enough; there is only one that is really permanent—that is the Bird's-nest hole.
8201. Are tube wells used in many parts of this district? No; there has been some boring done.

Loss of stock. 8202. *Mr. Murray.*] Do the stock die principally from want of water or want of grass? From want of grass; with water they might have lived a little longer. The grass is nearly always gone long before the water, except in some back places.

Artificial food. 8203. Do you not think that if they had had a partial supply of artificial food it would have saved them? It would have saved them.

Cost. 8204. You said you considered £1 a ton was the cost of producing hay? Yes, in ordinary seasons.
8205. And do you know how much hay a sheep eats per day? I do not.

Profit per sheep. 8206. Do you know the profits usually obtained from sheep in fair seasons? Yes; but I think the profits would be very small if the sheep were fed on hay. When they are fed on natural grasses the profit is from 3s. to 4s. a head. I think that in time of drought it would be quite sufficient if the sheep were saved without looking for any profit. If you have to feed a sheep on twice his value of hay it will not pay to keep him.
8207. The 3s. or 4s. profit you speak of is exclusive of the increase of the flocks? Yes.

Lucerne. 8208. *Mr. Targett.*] Good lucerne could be cultivated if the land were irrigated? On the river flats the benefit would be almost incalculable.

Price of sheep. 8209. *Mr. Murray.*] The average price of sheep is from 10s. to 15s., is it not? The average price is 10s.
8210. At what is considered sufficient to keep a sheep alive, you could keep about six sheep a year with a ton of hay: do you not think that would pay if you could produce hay at £1 per ton? I do not think you could produce it at £1 per ton, if you had to pay for water.
8211. *President.*] But would not the extra yield pay for the water? It might.
8212. *Mr. Gipps.*] What is the least quantity of hay you think a sheep could be kept on? I have not the least idea; I never saw a sheep fed on hay.

The Monkeys. 8213. Speaking of the Monkeys—do you sink through sandstone in them? In sand all the way.

Bottom. 8214. And do you bottom on rock? No, a sort of pipeclay. The water comes in from the sides, and wells up; and it maintains the same level, no matter how deep you sink.

Supply. 8215. Is the water sufficiently heavy to prevent your sinking? No; though there is plenty of water, thousands of sheep and cattle are watered there in times of drought.
8216. Does the quantity drawn from any well lower the surface? Yes, but only for a few minutes; it fills again almost immediately.
8217. *Mr. Targett.*] But you do not know that you would not get a larger supply if you went further? I do not think you would—I think you would lose it.

Mr. Craven Hyde Fitzhardinge called in and examined :—

Mr. C. H. Fitzhardinge.

29 May, 1885.

8218. *President.*] You are a solicitor? Yes.

8219. How long have you been here? Fourteen years—since 1872.

Floods.

8220. Have you seen many floods in the Macquarie? Yes. It is hard to define what a flood is in the Macquarie. I have seen many rises. We have had what we call floods—large floods—during that time.

8221. The rest have been rises? Yes; the water just coming over the banks. I had a photograph of one flood taken in 1879 (*Appendix* AA); it is the highest flood I have known, but I believe there was a flood 4 feet higher than that; it came up in Macquarie-street 18 inches higher.

Highest point.

8222. The photograph represents the flood at its highest point, and shows a view of the wooden bridge now across the river? Yes.

Current.

8223. *Mr. Targett.*] Is there a great current in the river at that height? No; the current leaves the river and goes nearer the town, over the flats which form the banks of the river. I have measured with a line from where the water has touched the top of the pier of the bridge in the flood photographed down to the present level, and I find it from 45 to 46 feet; the width would be from half a mile to three-quarters. The water rose one day and remained just over the banks, and was receding, when the Mudgee water came down, and the water rose again to height as shown in photograph. It remained up two days, when it fell to the level of banks, and rose again the following day just over the banks. This flood lasted four days.

Conservation.

The Talbragar.

8224. *President.*] Have you any knowledge of any point at which the Macquarie waters could be conserved on a large scale? I know several creeks. The Talbragar River would be a good place; it runs into the Macquarie about 4 miles above Dubbo. If it were dammed at the entrance it would throw the water back a long way. The banks are very steep, and the water would be conserved within the banks. The country is good holding ground. Then again, the Hyandra Creek, about 9 miles above Dubbo, on the Cainboogle Run, is a creek with very high banks in which water could be easily conserved and would be thrown back a long distance; but the land on either side is private land. Again, the Little River, about 14 miles by road, above Dubbo.

Hyandra Creek.

Little River.

Land.

8225. I suppose the land generally on the banks of the Macquarie from Dubbo upwards is private land? Mostly; some of it is reserved.

Dargindale.

8226. Are there any other places off the river wherein to conserve water? In the vicinity of Dubbo there are few; but about 50 miles down the river there is a place called Dargindale, on the Burraway Run; its extent is about 4 miles by 2. With a little expenditure I should say it could be made to conserve a large quantity of water. The depth is over my head, and the water could be artificially increased by means of a dam.

Lagoon.

8227. *Mr. Targett.*] What is the get-away—a creek? The water goes out over the country, and evaporates or is absorbed—it is a lagoon.

Euloon Cowl.

8228. *President.*] Are there any other places? Further down, about 15 miles, there is a place called the Euloon Cowl, which is supplied by the Macquarie River in very high floods. I have been on it in a canoe. It was fully 5 miles long, by 2 wide.

8229. And about what depth? I could not tell you. I should say that it was at least 14 or 15 feet deep.

Diversion.

8230. Could the water be diverted into that by any cutting from the river at a lower level? I do not think so—not where it comes in at present; but you might by striking the river higher up. The cutting would be very expensive and very long. The Cowl is about 4 miles from the river. What I should propose would be to dam the entrance to the Cowl so as to prevent the flood from running out after it had run in.

Macquarie banks.

8231. Do you think it would be dangerous to touch the banks of the Macquarie without using great care? Yes, for fear of its scouring. There are two places I may mention. In one the Municipality some years ago ran an ordinary 4 feet dam, and it is now an immense chasm. Again, the railway drain, which was originally 6 feet by 4 feet, has scoured to about 40 feet square.

Dams.

The Rocks.

8232. Do you know any parts on the Macquarie at which dams might be constructed with advantage? It is beyond my knowledge. There are places, but I do not know whether the dams would stand. There is a place at Burraway called the Rocks, 30 miles below Dubbo.

8233. Would a dam back the water a considerable distance? Yes; the banks are very high, and there is no great fall.

Dam at Browning's H

8234. Do you know of any points up the river? There is a place just about Dundulamil Station, and near Mr. E. H. Barton's farm; I think a dam could be made there with great advantage, near the foot of what is called Browning's Hill.

8235. Would a dam there cause the water to spread over a large part of the flats? Yes; it would spread until it reached the old original banks of the river on the opposite side.

At Old Dubbo.

Town supply.

8236. Do you know any other points? Up at Old Dubbo there is a place where you could get a rocky formation—a place where Mr. James, the engineer, has picked a site for the proposed water supply for Dubbo.

8237. Would that dam conserve a large quantity of water? Yes, a considerable quantity.

8238. Is it above or below the town? Above.

8239. Would it have a sufficient elevation to supply the town? Yes.

8240. *Mr. Gipps.*] By gravitation? Yes.

8241. *Mr. Targett.*] How far is it from Dubbo? Over 5 miles.

Quality of water.

Site for reservoir

8242. *President.*] That is as the crow flies? Yes. I do not think the water would be good enough for the town all the year round without filtration. I think there is a better site, and one handier to the town than that selected by Mr. James; it is on a hill overlooking the town. The formation there is sandstone, of which reservoirs could be made, and the cost of piping would be much less. It would be only a mile, or a mile and a half away, but on opposite side of the river from the town.

Percolation.

8243. Do you think there is much loss of water by percolation through the banks of the river? I know there is some, but I cannot say how much. I have noticed many times a strip of bank above the water line very wet and boggy, leading one to suppose that the water was percolating into the bed away from the river.

8244. If you see the banks soft and wet it would be an indication that the water was percolating? No; I should say it was soaking up by capillary attraction.

8245. You do not know from actual observation whether there is any great loss of water from one point to another on the river? No; I have noticed with astonishment the way the water goes, but I put it down to evaporation.

8246.

Mr. C. H. Fitzhardinge. 29 May, 1885.

8246. But it may be percolation? Yes; I have known the river to fall 4 inches in a day.

8247. That is from a low level? From a very low level indeed; in February, when the heat of the sun is very severe.

Irrigation.

8248. Have you had any experience of irrigation in a small way? Yes; I started irrigation about eighteen months ago, and raised certain crops with great success, although they were put in in a rough way and were left to take care of themselves. I raise the water by means of a Tangye pump. A wool-scouring establishment, in which I am interested, raises the water for wool-scouring, and after it had been used for that purpose I used it upon my ground and irrigated about 10 acres.

Crops. Barley yield.

8249. And what crops do you usually grow? First of all I grew Cape barley, of which I got an immense crop—so thick that the machines would not cut it. Then oats, then lucerne, and latterly, corn.

8250. How many tons of barley and oats to the acre were there? I had 2 acres of oats, and there were 14 tons of hay, estimated by farmers.

8251. That is 7 tons to the acre? Yes.

8252. And what was the weight of the barley? I could not give a fair estimate, because it could not be cut. It lay down, owing to the extreme growth. What I cut went, I should say, about 4 or 5 tons to the acre. The cornstalks grew about 16 feet.

8253. Have you any idea of the number of bushels to the acre? No; it has not been threshed yet.

Lucerne.

8254. How many crops of lucerne did you get from the irrigated land? I only got one, and that I fed down. It was an immense crop.

Windmills.

8255. Would it be possible to raise water by means of windmills for irrigation? Not unless you erected a reservoir and had a windmill to pump the water into it before you used it; you could not pump directly on to the land, to keep up a sufficient supply.

Reservoirs.

8256. Would it be possible to excavate banks so as to form reservoirs? Yes, if you raised them up so as to run the water off. A great many windmills are used for private gardens in Dubbo, and they answer very well. Flowers are produced very luxuriantly.

Extension of irrigation.

8257. Do you think that irrigation, if water were properly conserved, could be carried on on an extensive scale? I have no doubt it could.

Population.

8258. And if the country were irrigated would it carry a large population? There is no doubt about it.

Stock-feeding.

8259. You have had no experience in feeding stock with hay? No; but from inquiries I have made I have heard it would not pay to buy hay.

8260. Could you give any results of your observations as to evaporation? Not reliable information.

Water per acre.

8261. *Mr. Murray.*] Have you any idea of the quantity of water used per acre? No, I have not, because it is only waste water. While the machine is going the water is running. The pump throws 16,000 gallons an hour if required.

8262. How long is it working? It has been working for about six months, at eight hours a day.

Distribution.

8263. *President.*] How do you distribute the water? Through channels—one long one and several small ones.

8264. Is the large one at a slight elevation above the others? Yes.

8265. So that the water is raised above the ground adjoining? Yes.

8266. *Mr. Targett.*] At what intervals are your minor channels? About 10 feet, and about 6 inches wide.

Legislation.

8267. *Mr. Gipps.*] Do you think it advisable that future legislation on water conservation should provide that all the waters of the rivers, streams, and lakes, should be the amalgamated property of the State? Yes, decidedly. You were asking the last witness about the wind. I take the records for Mr. Russell. I find

Wind.

that the prevailing wind here in summer is south-west—that is the day wind. At night we generally get the wind from the north-east. That is a peculiarity noticed by Mr. Russell, for in Wellington and down the river they do not get the north-east winds.

8268. Are the winds regular and continuous? In summer the south-west wind is very continuous—it is a dry wind; as soon as it veers to the north-west we get rain.

8269. *President.*] Have you any instrument for testing the evaporation? No.

8270. There is an instrument in the town? Yes, kept by Mr. Jas. Heane, in charge of the Government machines for observing the weather.

Mr. John S. Brown called in and examined:—

Mr. J. S. Brown. 29 May, 1885.

8271. *President.*] You are a stock and station agent at Dubbo, and have resided in the district a great number of years? Yes, since 1863.

8272. And you have been here during some very high floods? Yes.

Floods.

8273. Is any large extent of country covered with floods back from the Macquarie? Yes, after it gets below Narromine.

8274. Do you know the nature of the Macquarie Valley, as to natural basins? Yes, I have travelled on each side of it for miles out.

Storage.

8275. Are there any natural basins up the course of the Macquarie above Dubbo where large quantities of water could be stored? Yes, I believe there are places where you could store large quantities of water.

8276. The country on each side of the river is high? Yes.

Flats.

8277. Are there large river flats? Not very large.

River-bed.

8278. Is the bed of the river large? Yes, it is wide, taking into consideration the size of the stream.

Places for dams.

8279. Are there any places where the hills come together at points opposite to each other, where dams could be thrown across? Above Wellington there are some fine places for storing enormous lakes of water.

Bars.

8280. Are there any bars of rock running across on which dams could be constructed? Yes, at numbers of places.

8281. Can you indicate any particular place? There is a place near the junction of the river with the Mucrawa, and above that for many miles there are numbers of places.

8282. Above that point are the natural places large enough to store large quantities of water? Yes, hundreds of feet in depth.

Loss of water.

8283. I suppose there is an immense loss of water in times of flood down this and other rivers that you know? Yes, enormous quantities.

8284. Do you think that if a large quantity of that water were impounded up the valley of the river it could be utilized for purposes of irrigation? Yes, for watering purposes, and perhaps to a certain extent irrigation might be carried out, but I think that the works for the storage of water above Wellington would be of a very gigantic description, because the mountains are very high; and if it were possible to throw enormous dams across from one mountain to another you would have enormous lakes with immense quantities of water, not only in the valley of the river itself, but also in the tributaries that come in on each side.

The Talbragar.

8285. Do you think any quantity of water could be stored along the valley of the Talbragar? I do not think so.

8286. Why? The ground is all of a sandstone formation, and I think the water would gradually percolate through.

Banks of Macquarie.

8287. But that is not the case on the banks of the Macquarie? No, because there is no sandstone in the Macquarie above Wellington.

8288. Is there sandstone below Wellington? Yes, a few miles below, commencing about Guerie.

8289. And all along the course of the river till you come to the plains you find these sandstone bars at various places? Yes.

Soil.

8290. I suppose the nature of the soil is such that it will grow anything as long as it is well watered? The soil will grow anything; all it wants is moisture.

8291. Do you know the country between Dubbo and the Macquarie Marshes? Yes, very well.

Creeks.

8292. Do you know a number of creeks that break off towards the Bogan? Yes.

Damming of the Macquarie.

8293. Do you think it will be practicable to dam the Macquarie down that part of the country and throw water along those creeks during the time of a fresh in the river? I do not think there would be any difficulty.

Off-takes.

8294. Would you suggest that that should be done in the natural bed of the creek as it is now, or would you deepen the off-takes from the river into those creeks? It would be better to deepen the off-takes from the river.

Scour.

8295. If the off-takes were deepened, would there be much scour? There would be scour.

8296. Do you think it could be prevented? I believe it could.

Protection of dams.

8297. In what way would you suggest? It might be done by means of timber—a floor of timber; but those are matters which are perhaps more in the province of an engineer. I know that on stations we protect dams with logs.

Wells.

8298. Do you know anything of the wells that have been sunk in this district? I know that a great many wells have been sunk.

Quality.

8299. And have they been successful in many instances? The wells about Dubbo all contain good water.

8300. Have you a well of your own? Yes, about 50 feet deep, with an excellent supply of good water, but it is affected by the river.

8301. Then it is river water? Yes, I think it is, because we sank into the old drift, the same that we now get in the river.

Windmill.

8302. Do you use a windmill pump to raise the water for irrigating your garden? Yes.

Wind-power.

8303. Do you find you have wind-power enough to raise all the water you require? Yes, with the size of pump that is used; but I could use three times the quantity of water if I had greater power to lift it. I question then, however, if my well would stand without being deepened.

8304. Is this a windy part of the country as a rule? Yes, very windy.

Direction of winds.

8305. There is always wind enough to drive a windmill? Almost always. I do not think it ever stood still for five days. We have wind in the evening if we have none in the day-time. In droughty weather the wind comes from the eastward, apparently; in the evening and during the day it blows a lot from the north-west.

8306. Do you know anything of the wells in the salt-bush country? Yes, I have seen a great many of them.

Good wells.

8307. Can you particularize any part of the country where good wells are to be found? I believe there is a very good well at Nevertire, which has been sunk by the Railway Department, but there are some that are very bad. Mr. Ryrie sank some wells, one about 380 feet deep, fifteen or sixteen years ago. The water was bad, and although the sheep drank it for some time, it was not suitable, and Mr. Ryrie discontinued the use of it. It was brackish to a certain extent, and very bitter. Then there were two or three wells that Mr. Brown sank at Cannonbar. The water in them was brackish. The Duck Creek water-holes are generally very large and deep, one 15 or 16 feet deep at Cannonbar, and nearly a mile long. It is well protected by trees, so that there is not much evaporation. Mr. Brown constructed a windmill, and sank a well in the bank of the creek some 10 or 12 feet from the water-hole. When he reached a point level with the water in the creek, and where he expected to find water, he found a clay formation in which there was no leakage from the creek at all, and he continued sinking until he got 2 feet below the level of the water in the creek, where he came upon white sand; a few inches further down he reached the water, which was as clear as possible, but as salt as the sea. The depth was about 12 feet from the surface. You could dip the briny water out of the well on the one hand, and you could dip the fresh water out of the Duck Creek on the other.

8308. Then that would indicate that there was a stratum between the well and the creek that prevented any leakage or any contact between the salt and the fresh water? Yes. Speaking of wells, I may also mention that on Beleringa there were two wells which Mr. Beard sank, and in which he found beautiful fresh water. The wells were sunk in Monkeys, that is, enormous cups filled with sand and having gum-trees growing on them. You sink into those cups and you find fresh water. They have clay bottoms, and you go through the sand to the clay. It is no use to go through the clay, because if you did you would very likely come upon salt water, but it is possible in some instances to pump those wells dry.

Wells in Monkeys.

Supply.

8309. You are speaking of local Monkeys? The station-holders have told me that the same thing occurs in the Big Monkey between the Castlereagh and the Macquarie—the wells there have also gone dry.

8310. What would you conclude from that—that there is a limited supply of water in that country? Yes, depending on the depth of the cups.

8311. You consider that there is a succession of cups in that sandy country? Yes, or bars may run across the Monkey in places.

8312. Do you know any instances of artesian water being found in the country this side of the Darling? No,

Mr. J. S. Brown. 29 May, 1885.

No, I do not know of any. I know of some very strong saline springs that when tapped come with a great rush, nearly rising to the surface. There was one on a barren plain at Brown's run out from Mudall. The rush of water was so great that the men could not get their tools out.

Boring. 8313. What was the best means you had for tapping the subterranean water—did you do it by an ordinary well or by means of tubing? By boring.

8314. Have you had any experience in boring for water? I have not.

8315. Do you think it better than sinking an open well? I think it is, because it seems to me that by boring you can test the country quicker; it is cheaper to bore than to sink I should fancy.

8316. And when water is found I suppose no person objects then to sink for it? No, I should think not.

Expense. 8317. The great expense in obtaining water arises from having to sink so many wells before water is found? Yes, you may sink a dozen wells before you find water.

Irrigation. 8318. Do you think that, if a large amount of water were conserved in the neighbourhood of the runs, the squatters would avail themselves of it to irrigate and grow produce to store for dry seasons? I think they would.

Water-rate. 8319. Do you think that the people, both squatters and selectors, would be willing to pay a reasonable sum for a good supply of water for both stock and irrigation purposes? I should think so. If I were one of them I should be inclined to do so.

8320. Do you think if that were done it would prevent the mortality that has occurred among stock during the last few years? I think, to a great extent, it would.

8321. Have you had any experience as to the quantity of hay necessary to keep sheep alive? No, I have not. I do not think it would take very much.

Water Trusts. 8322. Do you think it would be better in carrying out any works for water conservation that they should be done wholly and solely by the Government, or that there should be legislation to enable local Water Trusts to carry them out? That is a matter that requires some consideration. As to local Trusts, I am doubtful about them. I think it would be necessary for the Government to take the thing in hand, at the same time looking well ahead to the returns to come in from the outlay.

8323. Do you think that if the Government undertook some of the most favourable and most gigantic works to prove what the result would be, it would induce others, both private individuals and Trusts, supposing the latter were created, to follow the same course? I think it would have a very good effect.

8324. *Mr. Gipps.*] Why do you think that this work would be better carried out under Government direction than under the direction of local Trusts, seeing that in every country in the world such works are carried out by local Trusts, and that local people are more likely to look after them? I think it is a matter that is open to argument.

8325. Do you not think that the local people would know far better how to apply the water than a man hurrying up from Sydney and knowing nothing about the country? I think he should have a fair amount of time to make his examination and consult with the residents and practical men. Among local Trusts there is always so much difference of opinion.

Conservation above Dandaloo. 8326. *President.*] Do you know of any position above Dandaloo, on the Bogan, suitable for a dam and capable of storing large quantities of water for purposes of irrigation? I do not know of any; the country is too level.

Abyssinian wells. 8327. Do you not think Abyssinian tube wells would be applicable to the Monkey country? I think they would be worth trying. The water is not found at a great depth—not more than 14 to 25 feet. The Monkeys are different from the salt-bush plains. In a Monkey you can nearly always get water. We have no engineers in the bush, and the pumps would soon get out of order, so that where a well does not require to be deep, I think the simplest and cheapest plan is to sink a well in the ordinary way and draw the water up with buckets or some simple appliance. I think that in regard to the matter of conserving large quantities of water, the Commission would act wisely if they gave their attention to the country above Wellington.

THURSDAY, 18 *JUNE*, 1885.

At Sydney.

Present:—

MR. BARTON, M.P.,
MR. DONKIN, J.P.,
MR. FRANKLIN, C.E.,
MR. GIPPS, C.E.,
MR. LYNE, M.P.,
MR. M'MORDIE, M.I.C.E.,
MR. TARGETT, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. J. B. Meldrum, junr., called in and examined:—

Mr. J. B. Meldrum. 18 June, 1885.

8328. *President.*] Where do you reside? Tumbarumba.

8329. Have you been there any length of time? Now nearly five years.

8330. In what position? Road Superintendent.

8331. Under the Commissioner for Roads? Yes.

8332. Does your work take you all over the district? Yes, in the course of my duties I visit all parts of the district.

8333. You have had an opportunity during the time you have been there of becoming well acquainted with the natural features of the district? I have.

Road levels. 8334. In your official work have you taken the road levels? I have completed a series of levels from Tumbarumba, radiating all over the district—branch lines, which have all been reduced to one datum. I may say that since I have been there I have levelled the whole of the district, so far as the roads are concerned—at all events all the principal thoroughfares.

8335. Have you these levels with you? I have a condensed form, showing the difference in elevation of the main points in the district—the Murray River Valley and Tumbarumba.

8336. Will you submit those levels? The sketch I submit *(Appendix BB)* represents the various heights from Tumbarumba as the centre.

8337.

Mr. J. B. Meldrum. 18 June, 1885.

8337. You give the height of Tumbarumba as 2,950 feet? Yes.
8338. Burra 3,050 feet, and Boggy Creek, 3,005·95 feet? Yes.
8339. They are on the road from Tumbarumba to Tooma? Yes. Tooma at Woodhouse Bridge is 1,600·55 feet. Waleragang is 1,506·75 feet—it is a surveyed village reserve; Jinjellic Bridge, 20 miles from Waleragang, is 1,373·69 feet; and Maracket, 8 miles further down, is 1,328·90 feet. These are all levels along the road from Tumbarumba to Tooma, and from there along the Murray to Maracket. Levels from Tumbarumba to Maracket.
8340. You also give the height of a place called Lob's Hole? It is at a place called the Neurameramang Gap, Mr. Ricketson's station.
8341. You give the height there as 4,850 feet? Yes.
8342. *Mr. Gipps.*] Is that on the right or on the left-hand bank of the river? I cannot say that that is exactly the height above sea-level. I adopted the level as nearly as I could at Tumbarumba; the other is merely a barometric section. I suppose you would call it the west bank of the Tumut River.
8343. On the Kiandra side? No, on the Tumbarumba side—on the left bank of the river.
8344. *Mr. M'Mordie.*] If there are barometric readings and spirit level readings, ought they not to be distinguished? From Tumbarumba to the Tumut River they are barometric readings; on other side they are reduced spirit levels from Tumbarumba. Barometric readings.
8345. *Mr. Gipps.*] At what point did you take the height of the Tumut River? On the left bank, at the Wire Bridge. Height of Tumut River.
8346. *President.*] The height there is 2,400 feet? Yes.
8347. *Mr. M'Mordie.*] What is the datum of these levels? 2,950 feet at Tumbarumba.
8348. Is that height above the sea-level, the same as the railway datum? It is not to any definite datum; it is only adopted to show the difference of level between Tumbarumba and Maracket. Sea-level.
8349. *President.*] How far is it out from the sea-level? I cannot say; I have not tested it.
8350. Is it likely to be much out? I cannot say.
8351. Is there any bench-mark left from which these levels could be connected? I have a series of bench-marks from ¼ to ½ a mile apart; I left bench-marks all through. Bench marks.
8352. Where would the bench-mark nearest to the railway line be? At Maracket, I should think. There has been a preliminary survey of a line from Wagga to Tumbarumba. There is a bench-mark left at Tumbarumba.
8353. What is the level there? I have not connected the two, but I can do so when I return. My own bench-mark is in Parade-street, Tumbarumba. That would connect the whole of the levels.
8354. *Mr. Franklin.*] Is there a reference to the bench-mark at Maracket—where can it be found? It is on a tree—I cannot tell you exactly what tree; I think it is a white gum or an apple-tree. The last level taken by me is the last peg of the cutting at Maracket; it is at the upper end of the cutting.
8355. I suppose it could be pointed out without any difficulty? Without any.
8356. The whole of the pegs you refer to can be pointed out? Yes. At Tooma the connection is on the deck of the bridge.
8357. *President.*] In travelling about, have you noticed any place where you considered that any large quantity of water can be stored—take the Upper Murray first? I think that a large conservation of water could be made in the Tooma River, above its junction with the Tumbarumba Creek. The Welumba Creek, the Maracket Creek, and the Tooma River become one stream just before reaching that point. I think it is one of the best spots I have noticed. Storage.
8358. Is there any large basin above that point where water could be stored? It is all a natural basin there. The watershed is on three sides—from Tumbarumba, Neurameramang, and the right bank of the Tooma River. Natural basin.
8359. What would be the length of the dam at the point you mention? I may state that the point to which I refer is just above the point at which you were inspecting. There is another large rocky promontory immediately on the opposite side. I should say that the distance would be about 400 or 500 yards. The whole of the stream passes through that neck. Length of dam.
8360. Is there any large extent of banks there? You could throw the water back for miles. Back water.
8361. The fall is not too rapid? The Tooma is rather rapid, but the rest are only small streams. Fall.
8362. The fall of the country is not great? Not immediately; but when you get away about 2½ miles it becomes abrupt and broken country.
8363. How high would the dam have to be in order to store much water? I could not speak positively as to that point. I should say that it would require a very high dam. Height of dam.
8364. Do you know of any point further up the Murray where any large quantity of water could be stored? I have never been beyond Bringabronge.
8365. What sort of a valley is the Upper Murray—is it a rich valley? A very rich country. Upper Murray Valley.
8366. Rich agricultural soil? Yes; it could be used for agriculture, but it is now used entirely for grazing purposes.
8367. It is not heavily timbered? It is not timbered at all; the timber is dying.
8368. *Mr. Gipps.*] Is it not swampy in winter-time? It is very swampy; as you approach the river there is a succession of lagoons—that is, as far as I have been up. Lagoons.
8369. Do you know much of the head of the Tumut River? I have only been across once—about three years ago. I went up during the summer-time, and I examined the river carefully as I went up to report as to the possibility of a road being made across there. Tumut River.
8370. Where is that? From Tumberumba to Kiandra, at the bottom of Lob's Hole. It is rough, broken country. The fall is considerable, and the river runs rapidly.
8371. That is the Tumut? Yes.
8372. In that direction, do you know of large basins in which, by the erection of a dam, a large quantity of water could be stored? There is a point about 2 miles below the crossing-place from the Main Divide to the Talbingo Dam—to the foot of the Talbingo slope. There is a natural basin; the whole of Lob's Hole is a natural basin. Basins.
8373. Its outlet is into the Tumut River? Yes.
8374. What width is it across at the outlet? I really could not say. Width.
8375. Give an idea? It must be quite a mile or more; it is very wide.
8376. You have been up the Jingellic Creek to the Gap? I have sectioned the whole of the road from Jingellic to Tumbarumba over the Gap at Gad's Hill. The highest point between Tumbarumba and Jingellic is 800 feet above Tumbarumba. Jingellic Creek.

8377.

Mr. J. B. Meldrum. 18 June, 1885.

8377. *Mr. M'Mordie.*] Is that taken by spirit level? Spirit level—continuous sections from my central bench-mark at Tumbarumba.

Mannus Gap.

8378. *President.*] What do you pass over on the way? You pass over two ranges—one at the Mannus Gap. That is not more than 150 feet above the road to Tumbarumba, which is in a hollow. I should say that the Mannus Gap would be 300 feet above my bench-mark in Tumbarumba. The other gap is on Mundaroo Range; it is quite a low gap, about the same height as the Mannus.

8379. Have you any idea of the conformation between the gap at the head of Coppabella Creek and the gap at Gad's Hill? I cannot say; I have never been at Coppabella Creek.

Pass on Mannus Creek.

8380. Does not the road between the gaps pass over table-land? It does. I may mention that what they call the pass on the Mannus Creek, about 6 or 7 miles below where my road crosses, I fancy two large creeks unite—the Mannus Creek proper and Bell's Creek. They are both fairly-sized streams. The Mannus has a large natural bed, with hills all round. I think a large body of water could be conserved there.

Gorge.

8381. And the gorge is not very broad? Not very broad; it is comparatively narrow, I think.

Basaltic table land.

8382. *Mr. Gipps.*] Do you know the level of the divide as the road comes on the top—the basaltic table-land, where they are sinking a shaft to get coal? I did not think of it, or I could have put it on the section. It is 983·35 above Tooma.

Paddy's River.

8383. What is the level of the road as it crosses Paddy's River? I can give you that also. It is 1,298·96 above Tooma.

8384. That is close to the Burra? About 4 miles and 25 chains from the Burra. I think it is higher than Boggy Creek; I can give you the exact level of any point on that road. I will send you a sketch section showing all these points as connected with Tumberumba when I can find time to do so.

Checks.

8385. *Mr. M'Mordie.*] What checks have you had on the levels with which you have supplied the Commission? I have checked them as I progressed. I checked them by a series of falling levels.

Error.

8386. What is the greatest error you found in enclosing any circle? I used to take about every quarter of a mile—a little more if the country were open; in rough country, less. It would vary from fifty to seventy-five points—sometimes an inch. I have been as much as an inch out occasionally, owing to unforeseen circumstances arising in connection with the instrument or a mere accidental slip.

8387. You did not enclose any very large circle? No, I did not. For my own convenience and security I checked them at very short intervals—not more than a quarter of a mile at any time. I have corrected repeatedly on my bench-marks.

Work for Commission.

8388. Could you undertake any work for the Commission, or is your time fully occupied by official duties? At the present time I have rather more work than I can contend with; but in a month or more, when I get my camp off my hands, I may be able, with the approval of the Commission, to do something for them. My work will not be so heavy then.

Area of Lob's Hole.

8389. *Mr. Franklin.*] You mentioned Lob's Hole—is that a large area? Lob's Hole, from the crossing at the Wire Bridge to what they call the Walls, where the passage is, would be I think about 8 miles in length, and I suppose in width it would be about 5. It is a regular valley, with precipitous mountains on every side.

Outlet.

8390. Is there a depression lower than the outlet? The only outlet is the Tumut River.

8391. Is there a constant deposit of water in the Lob's Hole? No; the drainage is all towards the Tumut River.

8392. What is the approximate catchment area of the Lob's Hole? I have no data; I only made a flying visit.

Fall.

8393. I suppose there is a general fall from the centre towards the outlet? Yes. I may mention that the Yangobillie is a stream about the same size as Paddy's River—about the same volume.

The Yangobillie Dam.

8394. Any large volume conserved there would be due to the height of the dam? Entirely. The dam would be about a mile in extent—probably more; but I think a large body of water could be conserved there, and I think the elevation is sufficient. The only thing is to get a leading range by which the water could be conveyed to lower ground. I cannot speak positively as to that.

Formation.

8395. What is the nature of the formation at the site of the dam? It is all rock.

Rock.

8396. What rock? Granite, I think, principally.

Artesian water.

8397. *Mr. Donkin.*] Has any artesian water been discovered in your district? The only boring I know of is in connection with the gold-mining claim on the Bald Hill, on the basaltic range overlooking Tooma. I cannot state the depth. I know the boring is there, but I do not know the result. They were boring to find bottom if they could—to find a wash. They are tunnelling now. The whole of that district is one mass of springs in every direction—in any spur or gully there are springs—water is running continuously.

Springs.

8398. Do you know of any large supply coming out of one place? No, I do not.

Old tunnel.

8399. *President.*] Do you know of an old tunnel above Tumbarumba? On the left-hand side as you ascend the creek I believe there is such a tunnel, but I have never seen it.

8400. Could you obtain for the Commission some of the deposit taken out of that tunnel, and which is now lying near the mouth of it? Yes, I could.

8401. They are tunnelling, you say, on the Bald Hill—is that through granite? I think they are tunnelling through the granite.

8402. Right into the heart of the hill, at a point where the granite and basalt meet? Precisely; the wash which contains the gold is on the top of the granite, between the granite and basalt.

8403. What is the height of the hill above where they are tunnelling? 500 or 600 feet at the least.

8404. A short time ago did you receive a telegram from me asking you to meet Mr. Gipps? I did.

8405. And did you reply that you would do so if you could? I said I would use my best endeavours to be there.

Meeting with Mr. Gipps.

8406. You did not meet Mr. Gipps? I did not do so, and I will explain why. I was away on a tour of inspection; I was down at Dora Dora; I did not return, I think, till the Monday evening or Tuesday morning. I received your telegram on the following morning; I wired to you that I would meet Mr. Gipps if I could; I sent another telegram to the Commissioner, containing your request and asking for his instructions.

8407. Did you get any reply? I got a reply to await instructions.

8408. You have not received any further instructions? No.

8409. Why did you not let me know that you were not going to meet Mr. Gipps? I expected to hear on the Tuesday or Monday. My reason for not further telegraphing to you was that I thought Mr. Gipps had probably

probably been there and returned, as the day upon which I was to meet him had passed. Not receiving any further communication from the Commissioner, I did not proceed. It is one of the departmental regulations that I should receive all instructions through my chief. Mr. J. B. Meldrum. 18 June, 1885.

8410. Had you met Mr. Gipps you could have given him the information you have given us as to the levels. Yes.

8411. Waleragang is in the centre of your work? There is only a small contract going on there now.

8412. Had you so much work on hand that you could not have met Mr. Gipps, supposing you had not received a telegram from the Commissioner? I was very busy at the time, as I always have been.

8413. But you could have met Mr. Gipps? Yes, if I had received instructions.

8414. That was the only reason you had for not meeting him? Yes; I should have been only too happy to give any information of the kind.

8415. You and I had a conversation on the tram some time before about this matter, had we not: Did I not explain to you that Mr. Gipps was going to the Upper Murray, and that I would like you to let him have the levels? I do not quite remember it; I have no doubt that that is the case.

8416. *Mr. M'Mordie.*] You say it is a rule of the Department that you should not leave your work without instructions from the Head of the Department? That is one of the departmental regulations. Departmental regulations.

8417. Do you think it is a good and useful regulation? I cannot speak as to that.

8418. Do you think it would cause inconvenience to public work if you were liable to be called off by any one except your superior officer? Undoubtedly, because during my absence the men would be waiting for measurements. Works have to be set out, and they would have to be held over until my return. Without a special authority from the head of my Department I could not leave my work or the district; I could not take up any matter foreign to my Department.

8419. Is that a good rule in the management of a large Department? I think so, as far as I can see. In the present case, when I received the paper requesting my presence here to-day, I referred it to the Commissioner, and received instructions from him to proceed to Sydney.

8420. *President.*] The telegram I sent you did not necessitate your coming out of your district? No.

8421. How far from the place was the centre of your operations? In a straight line about 25 miles.

8422. *Mr. Franklin.*] Your projected work in the district is reported to the Commissioner? Yes.

8423. And he approves and instructs you to proceed, or otherwise? Yes.

8424. *Mr. M'Mordie.*] Did you receive your summons to attend here to-day through the Commissioner? No; directly through the Board. It did not come from my office in any way.

8425. *Mr. Gipps.*] Were you not down at Jinjellic the day before I arrived? That is where I came from. I received Mr. Lyne's telegram on my arrival on Monday evening. I returned home too late to wire that night.

8426. Do you receive actual definite instructions as to inspecting the roads? No.

8427. Since that time have you not been inspecting the Upper Murray Road? Yes; I came along that way last Saturday. I passed Waleragang.

Mr. Harry A. Gilliat called in and further examined:—

8428. *President.*] You have given evidence to the Commission before? I have. Mr. H. A. Gilliat. 18 June, 1885.

8429. After examining that evidence, you desire to give additional information? I do.

8430. And you have prepared certain statements on two papers? Yes.

8431. Will you kindly read them? Certainly.

Witness read the following papers:—

MINUTE PAPER.

Subject:—Notes on the mud-springs and some of the shafts and borings for underground supply on the road between Ford's Bridge (on the Warrego River) and Hungerford (on the Paroo River).

Department of Mines, Stock Branch, Bourke, 25 May, 1885.

HAVING recently completed an inspection of the mud-springs on the Bourke to Hungerford Road, with the view of their being utilized in permanently watering this important feeder to the Railway at Bourke, I have the honor to submit, for the consideration of the President and Members of the Royal Commission, Conservation of Water, the following memoranda:—

The distance between the Warrego and the Paroo by this road is about 100 miles, and the general direction north-west.

The first of this series of springs is the Coonbilly, about 22 miles from the Warrego; but as it is some miles off the traverse of the new road, and has, I understand, been dealt with by another witness, I pass it without notice.

The Yungarrina spring (1A on tracing—*Appendix* CC 1) is about 27 miles from the Warrego, and one of the largest, with an area of about 4 square chains. The highest part of the mound—which in most places is sufficiently firm to bear the weight of a man—is about 3 feet above the level of the plain; in the centre a roughly-timbered shaft has been sunk some 6 feet in depth, and the water stands in it about 2 feet 6 inches above the surrounding level, and overflows both from the shaft and other portions of the mound into trenches, some 2 and 3 feet deep, that have been cut around two sides. The overflow from these finds its fall for about half a mile on to the plain, where it disappears, from evaporation, absorption, and consumption by the stock in the neighbourhood. I saw a 400-gallon tank filled by baling from the shaft, and found the water lowered 9 inches. In its present unimproved state, and allowing for the waste over the plain, I do not think the supply can be estimated at more than 1,500 to 1,800 gallons per diem. The quality of the water is excellent.

There is an outcrop of quartzite 25 feet above the level of the plain about 500 yards east of the spring, and indications of the same ledge to the north.

The Boongunyarra Spring is about 6 miles beyond. All indications of the old mud-spring, if there was one, have disappeared. The present basin has at some time been dug out, and apparently has been so poached by the trampling of cattle that the overflow I noticed four years ago has ceased, and the water stands about 6 inches below the edge of the basin, an occasional bubble indicating the pressure of water from below. At present the supply must be very limited.

Half a mile beyond is the Black or Back Spring. No attempt appears to have been made to open this. It is overgrown with weeds, and for an area of about a chain square covered with black vegetable ooze and water. I noticed the skeletons of several bullocks that have been smothered in it. I anticipate a strong supply will be obtained here. On the north and west outcrops of the same quartzite ledges previously noticed occur.

Mr. Langloh Parker's manager (Mr. M'Crae), at his camp, half a mile beyond, has put down a shaft about 50 yards south of an old spring not flowing or boggy on the surface, but quaking under foot. Mr. M'Crae was unfortunately absent, but from what I could learn in the camp the shaft is about 27 feet deep, and 8 or 10 feet in the rock.* At that depth the water was struck, and rose 19 or 20 feet in the shaft, in such strong supply that 10,000 sheep were watered at it during the late drought. A selector has put down another shaft a few hundred yards away and struck the same water. The quality is good for stock, but too brackish for domestic purposes. *Quartzite. Since confirmed by Mr. M'Crae.

12 miles from here is the Yantabulla group, the most numerous on the road; the first and largest is the Whip Spring, quite unimproved, but from which there is a considerable outflow, there being quite half an acre of water around it. There are large outcrops of the quartzite to the north and east of the springs, and between the Whip Spring and the principal

Mr. H. A. Gilliat. 18 June, 1885.

group there is a ridge evidently of the same formation. Mr. Buckley, the landlord of the inn, informs me that he has put down nine or ten shafts, most of which proved salt, and all unfit for domestic purposes, except the one he has now in use. This is sunk 40 feet in an old spring, and bottomed on sandy drift, the water rising to within 10 feet of the surface; the shaft is circular, and walled with stone. He adds that, when the well is baled out, a person standing in it can hear the mud working and moving on all sides. The water is fairly good and used for all domestic purposes, but appears impregnated with soda. Buckley states the daily yield at about 150 gallons, but I have reason to think this is very much under-estimated.

(say 2,000 gals.)

A few hundred yards from this well is another spring, where an old Chinaman has formed a garden; he dug out some 400 cubic yards from the spring, and told me that the blue mud forced up from below had driven him out several times, until he carted in a number of loads of stone. It yields him, he says, from 600 to 700 buckets per diem; but as he spoke very imperfect English I cannot depend on his figures.

From here to the Warroo Springs is 32 miles. At 2 chains from it, the manager of Brindingabba, Mr. Rudder, informs me, he sank a shaft 20 feet; the water rose in it 18 feet, very salt (No. 3 tracing). 5 chains east of the spring he sank a shaft 60 feet, and bottomed on blue mud, which broke into the shaft with such force and in such quantity as to compel its abandonment. Apparently a great supply below the mud. The Warroo Spring is 17 miles south-easterly from Hungerford, and 15 miles south from it is the Tyngynic group. A mile to the east of these Mr. Rudder put down a shaft for 60 feet through black clay, and obtained a supply of from 7,000 to 8,000 gallons of salt water. A 5-inch bore was then put down for 230 feet, through white clay and black drift, and abandoned in the latter (No. 7 tracing).

*The portion of tooth I exhibit from this spring is that of diprotodon.

At the Tynganic Spring, a shaft 20 feet deep struck salt water in white drift and water-worn boulders. No supply in this shaft. 15 feet below the surface were found fossil remains of a mammoth kangaroo.*

The Tynganic Spring itself yields excellent water, in sufficient supply for a boundary-rider's hut.

Quarter of a mile south-west, on the Willera Run, the owner has sunk a shaft 40 feet and obtained a supply of excellent water, estimated at 10,000 gallons per diem; the shaft is near another group of springs, and between them and the Tynganic.

* M'Comas offered to make the Paroo run by using his lifts at these springs.

I am not acquainted with springs south of these, with the exception of the Goonery, Wee Watta, Mullyeo, and those at the Peri Lake, on the Lower Paroo, where the supply, although almost unimproved, is sufficient to water 20,000 sheep.*

To the north they are of frequent occurrence, both up the Warrego and up Cooper's Creek and the Mitchell; and down the Cloncurry and Flinders, the most northerly, I am personally aware of being a group just under Fort Bowen, between the Flinders and the Saxby Rivers. I have also heard the Rev. J. E. Tenison-Wood speak of having seen them in Western and South Australia.

I may add that where I have noticed the outcrop of ledges the springs are apparently more numerous or the supply more plentiful. The ledges, I have remarked, are north of the springs. If there is a subterranean flow, this may indicate that it has a northerly direction.

My inquiries as to the effects of the weather on the springs have met with the same reply—that they rise before wet.

Mr. Rudder (Messrs. Christian's manager) has kindly furnished me with the following particulars in connection with the search for underground supply on Brindingabba:—

Shaft No. 1 (see tracing).—Depth, 66 feet; 94 feet of 3 × 3 feet drives at bottom; red sand at surface; reddish clay with gravel to clay-slate, in which water was found. Supply: watered 12,000 sheep through the recent drought. Quality excellent, and used for domestic purposes.

Shaft No. 2 (tracing).—120 feet deep; strata, red clay, 18 feet; then blasting through 14 feet of rock, then through soft white sandstone, till the water was struck. Water rose 90 feet in shaft, the same level from surface as at No. 1; 40 feet of 3 × 3 drives at bottom. About 4,000 gallons per diem. Same quality as at No. 1.

Shaft No. 6 (tracing).—150 feet deep; 5-inch bore, 83 feet. Supply, 100 gallons per diem. Good water.

Shaft No. 9 (tracing).—38 feet 5 inches; bore, 197 feet; stiff blue clay in shaft; bore through various clays, with lumps of pyrites near the bottom. Water salt; supply, 4,000 gallons per diem.

Shaft No. 10 (tracing).—35 feet. Salt water, very bitter; no supply.

Shaft No. 11 (tracing).—Over 100 feet deep. Supply small. Water analyzed in Sydney, and said to contain a powerful mineral poison; Mr. Rudder thinks, but is not sure, that it is arsenic.

Caiwarra artesian-well, on Togwarrah Run, across the Queensland border from Brindingabba, 135 feet deep, of which 50 feet is said to be through granite. While drilling the bottom broke through and the water spouted up; it rose in the shaft till it flowed over the surface; quality of water, first-class.

Boring with a 5-inch Tiffin machine, Mr. Rudder gives his average progress per diem at 16 feet through clays, 18 inches through rock.

HARRY GILLIAT,
Chief Inspector Public Watering-places.

MINUTE PAPER.

Subject:—Notes on some localities for conserving water west of the Darling River.

Department of Mines, Stock Branch, Bourke, 28 May, 1885.

I BEG to submit, for the consideration of the President and members of the Royal Commission on the Conservation of Water, the following memoranda:—

1. That the Darling and its tributaries may be regarded not only as collecting the flood-water of the rainfall in New South Wales, but in a large measure as channels that bring in from Queensland great bodies of water falling in that colony during the more or less regular tropical rains over their watershed, and that it is of frequent occurrence that these streams come down in flood without any or with a small rainfall in this Colony.

2. With the limited rainfall of the west, this supply must, I think, be regarded as an important factor in any measures dealing with water conservation in this region.

3. It may perhaps be of some service, commencing in the extreme north-west, to notice some of the streams and water-courses, pending survey, that appear to offer some of the necessary conditions for service in collecting flood-water into natural or artificial reservoirs.

4. Commencing with the Evelyn Creek, which rises in two heads among the low ranges around Mount Poole, in the bed of which are Depôt Glen water-hole—Sturt's Water-hole, and lower down, the Milparinka—and others of more or less value for stock and local supply. The creek, after a course of some 70 miles, empties into Lake Cobham; its catchment ground, consisting of low rolling downs and plains, with a firm pebbly soil, collects water so rapidly that an inch of rain will send it down for 50 miles. It is at present the principal, if not the only, feeder of Lake Cobham, 8 miles in length by 2 miles in width, filled by the last January rains, and now 27 feet deep. This water will last, according to the local estimate, nearly three years.

5. Some 50 miles to the east of the Evelyn Creek, the Bulloo River, rising and fed in Queensland, crosses the Border and at once runs out into an overflow which, when the tropical rains send the Bulloo down in flood, wastes into a large shallow bed known as the Carypundy Swamp, some 70 miles in length by varying breadths, where it soon disappears from absorption and evaporation.

6. Between the Evelyn Creek and the Bulloo, and also heading in Queensland, a creek comes down in which is the large Wampah Waterhole; this runs into the Whittnabreenah, which, flowing to the south-east, is perhaps the main feeder, but at all events runs very close to the Taltachara and Terrawinda Creeks, emptying into Lake Yantara, about 14 miles in length by 6 miles in width. About 12 miles south-west of Yantara lies the Salt Lake, of still larger dimensions, and a mile beyond Lake Cobham previously described.

7. A preliminary survey and computation of the flood-water of the Bulloo will of course be required. This being satisfactory, I think very inexpensive works, chiefly levees, will be sufficient to divert the Bulow overflow, or a portion of it, before it wastes into the Carypundy Swamp, into one of the channels of the Whittabreenah, the Taltacharra, or the Terrawinda Creeks, by that into the storage of the Yantara Lake. This filled, the overflow, if sufficient, to be led by improving the present channel into the Salt Lake, and thence to supplement the supply given by the Evelyn Creek and to Lake Cobham; conserving, if the scheme proves practicable, in these three large natural reservoirs, water collected at periods when there has been but a limited or perhaps no local rainfall. Actual survey will be required to indicate how far these lakes and the channel fillings them may be tapped for the supply of artificial reservoirs.

8. The Paroo River affords an opening for a plan of far more importance, and at an outlay so small in proportion to the bodies of water that may be conserved, that it will, I think, be found unequalled on any river in the Colony. (*Appendix* CC 2). After careful examination, I am strongly of opinion that the substitution of weirs for dams on the Paroo, and the construction

construction of low levées where required, to confine the flood-water and prevent its wasting over the great cane-grass swamps and clay-pans that for many miles of its course form the only apparent bed of this river, will cause to fill, with a minimum flood, the great chain of water-holes and lakes along its course, ranging from half a mile to 12 miles in length—such as the Warramurtie, Tongo, Yantabangee, Opeloko, Lakes Peri, Dick Copago, and others, where the water now rarely reaches unless in exceptionally heavy floods—affording storage for immense bodies of water, extending certainly to within 20 miles of Wilcannia, and probably further. How far these great natural reservoirs may be utilized for distribution must be determined by survey, but from the character of the country I think it probable very simple works will be found sufficient. Mr. H. A. Gilliat. 18 June, 1885.

9. The Cuttaburrra overflow.—The Cuttaburra is an effluent from the Warrego, and flows (as shown in tracing B) as a creek to the Mukajooro Waterhole, below which it wastes over the plains between the Warrego and the Paroo, and in a few miles spreads to a width from 1½ to 10 and 20 miles, and during a flood appears like an inland sea, contracting and expanding according to the features of the surrounding country, and in heavy floods extending as far south as Gorimpo. This overflow, if confined by levees, might be tapped on either side of its course as required, to fill tanks conveying the surplus, as found, after survey, most suitable to swell the supply of the Darling or Paroo.

HARRY GILLIAT.

Caiwarra spring.

8432. *Mr. Donkin.*] Is the Caiwarra spring still flowing? I understand it is.

8433. You do not know the supply? No; but it must be considerable, from its filling the shaft.

8434. Is the shaft slabbed? Yes.

8435. You spoke of Mr. M'Comas being on the Paroo;—where did he intend to bring the supply from? From Peery Springs. They are directly in the bed of the Paroo.

Peery Springs supply.

8436. Is the supply at Peery Springs larger than the supply from Yantabulla? Yes.

The Paroo.

8437. That is about where the Paroo runs out? The Paroo runs, in flood, for 40 miles below the Perry Springs.

Run of springs.

8438. *President.*] Have you come to any conclusion as to the run of these springs—can you define it as being in any direction? I am convinced that Mr. Wilkinson's view is right—that they are subterranean waters forced up along a great fault in the cretaceous bed running across from south-east to north-west.

Subterranean waters.

8439. From that would you suppose that the whole country underneath contained these subterranean waters? I am convinced, from the results of our boring, that the whole of this cretaceous area is water-bearing at a certain depth.

Artesian water.

8440. Artesian water-bearing? Yes.

Suggestions.

8441. Is there any particular point outside of the papers you have read as to which you think your evidence would be of value to the Commission? In reading this first paper upon some of the localities for conserving water, I merely read it as a series of suggestions that are not only applicable to the one stream but to all the streams upon the Darling watershed; for instance, the Warrego, the Culgoa, the Biree, and the Narran could be dealt with in the same way.

The Willandra.

8442. Do you know the features of the Willandra Billabong? I know the Willandra Billabong breaks away from the Lachlan, near Hillston, and wanders for a number of miles across the plains to the south-east of Lake Terrawynna.

8443. In the flood of 1870 do you know how near the waters of the Lachlan and Darling approached each other? I think in my former evidence I gave the distance as within 15 or 20 miles.

Mud springs country.

8444. *Mr. Targett.*] What is the length of the country upon which these mud springs continue? In the particular line to which I have referred the distance would be about 75 miles; but they extend for 180 miles up the Warrego, 200 miles up Cooper's Creek; on the Mitchell, 300; and down the Cloncurry and Flinders, 350.

Course.

8445. Is the course well defined in most cases? They appear in lines following the course of the Warrego fairly direct. They are running at an entirely different angle up the Warrego—north-east and south-west—and in the other cases I have illustrated on the map (*Appendix* CC 1) the direction is north-west, apparently leading to a junction.

Wampah waterhole.

8446. *Mr. Donkin.*] Is the Wampah waterhole permanent? I have never heard of it being dry. We have not a long knowledge of it. It is about 2 miles in length, and is about 27 feet in depth.

Tongowoko Creek.

8447. Do you know the Tongowoko Creek? Yes; the whole of that country has small water-courses running through it.

Yancannia hole.

8448. You did not mention the Yancanntia Waterhole; that is permanent? Not more than any other. It is on the map; but I did not mention it because it does not come within the scheme I mentioned to the Commission.

Bulloo River.

8449. You spoke of the Bulloo River running into the Carypundy Swamp; in that swamp are there any springs similar to those on the Paroo? I have not seen any in the part of the country I have been over, but I have not been over the whole of it.

Artesian well.

8450. You mentioned an artesian well on the Caiwarra Run? Yes.

8451. Do you know of any other instances of artesian supply in that neighbourhood? There are artesian wells at Wee Wattah and Mulyeo.

Supply.

8452. Is the supply constant there? The supply from Wee Wattah when the bore was first put down was the largest supply of artesian water struck in this Colony. At one time it was equal to 50 gallons a minute, but they lost it in sinking, and they have not since obtained so large a supply. When I was last there, to the best of my recollection, they were getting about 8 or 9 gallons per minute.

8453. You do not know of any larger artesian supply in the Colony? No. It all depends whether we adopt as artesian any water that rises above the surface or that rises only to a particular distance in the shaft. In one or two cases on Dunlop the water has risen from a depth of from 400 to 600 feet to within 20 feet of the surface. Probably if the shafts had been piped the water would have come over the surface.

Sinks.

8454. *Mr. Gipps.*] Are there any sinks in the neighbourhood of the mud-springs? I do not know of any sink in the Colony, except at Lake Narran. I have seen plenty of sinks on the west coast of the Pacific. At Lake Narran there is undoubtedly a sink.

Coolaman holes.

8455. Are there none on the other side of the Darling? I have seen small coolaman holes where local flood-waters will run away, but not where any large body of water disappears.

8456. Are there any of these coolamans in the neighbourhood of the mud-springs? I have seen none.

8457. Are there no sink-holes at Goonery close alongside the mud-springs? Not to my knowledge; I have not noticed any. I know that the old bore is down in the swamp where the old spring was.

Line of rock.

8458. *President.*] In one of your papers you said that north of the springs, as a rule you find a line of rock? I said that the ledges I had noticed were all to the north of the springs.

8459. Would you infer then that the drainage into this cretaceous formation is all from the south? I am not prepared from evidence to make any actual inference. I take it as a possible indication that if there be an underground current, which there may not be, the flow is northerly.

8460.

Mr. H. A. Gilliat. 18 June, 1885.

8460. Can you give no definite information on that point? Nothing more than that some geologists consider that there can be no break away for an underground supply beneath the old Barrier Range and the range which comes up by Cobar and Dunlop; they think that if there be a subterranean flow the escape must be to the north.

8461. If it comes from the south or east it does not come from the Queensland watershed? The statement that the ledges are north of the springs need not interfere with the supposition that the waters might come from Queensland or eastern watersheds.

THURSDAY, 25 *JUNE*, 1885.

Present:—

MR. DONKIN, J.P.,
MR. LYNE, M.P.,
MR. MURRAY, M.P.,
MR. TARGETT, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. George Frederick Ritso called in and examined:—

Mr. G. F. Ritso. 25 June, 1885. Malvern Waterworks.

8462. *President.*] What is your profession? I am a civil engineer.

8463. You have practised in New Zealand, I believe? Yes; I was Engineer of the Malvern Waterworks, Canterbury, N.Z.

8464. And you wrote the paper which you now hand in respecting those works?* Yes. The object of the paper was to illustrate the method of distribution and the method of construction of the falls carrying the water down to the plains.

Supply.

8465. Are these extensive works? They supply 90,000 or 100,000 acres of land with water.

Head works.

8466. Is that done by diverting a stream or conserving the water at the head of a river? By means of head works, which divert the water from the river Kowai on to the Canterbury plains. First of all there is a tunnel, and then open channels. The tunnel is a little over half a mile in length, and that conducts the water into an open channel, and thence down the Canterbury plains.

Cost.

8467. Have you any idea of the actual cost of the work? About £35,000 has been expended altogether in making surveys and constructing the works.

8468. What were the ruling rates for labour when the works were constructed? The concrete falls cost from £2 to £2 5s. per cubic yard; the falls at the upper portion of the work cost £5 each; that is with Portland cement at from 16s. to 18s. per cask; of course the shingle was on the ground. The timber falls cost about 18s. each, the Council supplying the timber and cement; the total cost of the timber falls was about 30s. each. The earthwork in the main channel, where spades were used to any extent, cost from 7d. to 1s. per cubic yard; but when we got lower down we divided channel into smaller channels, and then the work was done at per chain. When we came to make the channels from 7 to 8 feet wide the cost was about 5s. per chain, or about £20 per mile. Lower down, when we came to make channels about 3 feet wide, the cost was about £4 per mile. I may state that on works in the Ashburton district a specially designed plough for excavating was used; this plough would take out in a single ploughing 2 feet 6 inches of earth; it was drawn by 7 or 8 horses, and it threw the earth on each side in a kind of bank. The man who used the plough was the contractor for the work in the Malvern district; but in forming the channels there he preferred to do the work with an ordinary scoop, as the plough was hardly wide enough for the channels that we wanted.

Distances.

8469. What distance was the water conveyed? From the head works to the seaboard the distance is about 40 miles, and the width of the country from the head works to the railway line is about 25 miles. The water is taken from the Kowai River into a tunnel 46 chains in length, and thence into an open channel 12 feet wide, with 250 falls. The channel is then divided into two channels, each 8 feet wide, with timber falls, of which there are 2,300 in the channels. Further on these two channels are divided into smaller channels without falls. These small channels are about 3 feet wide, and it has been found that the water runs through these without scouring the ground. The great difficulty which had to be contended with in carrying out the works was the fall, which is about 80 feet to the mile at first, gradually diminishing to nothing at the seaboard. About half-way down the fall is about 20 feet to the mile. The fall is most regular, gradually diminishing all the way.

8470. What was your position in connection with the works? My work commenced when the provincial Government undertook the head works; I was then assistant engineer under the provincial engineer. When the provincial Governments were abolished the general Government took over this work and took me over with it as resident engineer. It was then handed over to the Selwyn County Council, and for a time I had nothing to do with it. Another engineer was placed in charge, and he put in about 2 miles of race about a third of the way down, which came to grief during a flood, owing to improper construction. I was again appointed engineer for the works, and I completed them.

Result.

8471. Has the work been a success, as far as the irrigated country is concerned? Yes, a great success.

Enhanced value of land.

8472. What do you consider has been the increase in the value of the land which has been irrigated over its value in its original state? It is difficult to estimate that exactly; but I should think about £2 per acre is the increase in value due to the fact of the district being supplied with water. Irrigation proper is not yet practised to any extent in the district. Land in the district would not be worth more than £4 per acre without water, and with water it is worth £6 per acre now.

8473. Not more than that? No; you must remember that the whole country is in a very depressed state. I think that my estimate as to the increase in value is a moderate one, because the value of land differs considerably, and the value of some classes of land has increased more than that of others from water supply.

Use of water

8474. *Mr. Donkin.*] Was the water used for pastorage or cereals? It is an agricultural country; there is about a foot of soil—good in the production of wheat—on top of an immense bed of shingle. Generally the land has been ploughed up and two or three crops taken off it when it has been laid out in grass for three years or so. The water has not been fairly used for irrigation up to the present—in fact it is regarded more as a supply for domestic purposes—but in one case a farmer irrigated about 300 acres; that was before the water was distributed below; he had the full use of the water, and he ploughed furrows all over his land

* *Vide* "Proceedings of the Institution of Civil Engineers," vol. lxxiv, Session 1882-3, part iv.

Mr. G. F. Ritso. 25 June, 1885.

so as to thoroughly irrigate it. The result was that he got such an immense growth of grass in the summer-time that he was able to let the land at a rental of £1 per acre for some years; the growth of grass was so astonishing that people went up there to look at it; it was principally rye-grass.

Purpose of works.

8475. *President.*] Then the scheme is for the distribution of water for general purposes rather than for irrigation? The idea is to educate the people up to the value of irrigation by giving them water to make use of in any way they may desire, on their various blocks of land.

8476. The races are not intended for irrigation purposes? They are distributing and not irrigating channels.

Irrigation.

8477. Then the increased value of one-third of which you place on the land is the increase arising from water distribution and not from irrigation? Yes; the fact of the matter is that the people have no idea of the value of irrigation, and I do not know whether in this case the supply of water is sufficient for the purpose; the supply is about 200 gallons per acre per diem, which is not very large.

8478. Was the work undertaken by the Government as a kind of specimen work? I do not think so. In 1873 the Government proposed a vote of £25,000 for the work.

Object of works.

8479. *Mr. Donkin.*] Was the object of the work to supply Canterbury with water? No; an influential land-owner in the centre of the plains had been an Indian officer and he knew a great deal about irrigation; he had no water and no possibility of getting any unless it was brought down from the river; he knew that that could be done, and being a member of the Legislative Council he never rested until the Government voted a sum of money to be expended in the work.

Regulation of supply.

8480. *President.*] It had no further significance than that? No; the whole district was destitute of water.

8481. *Mr. Donkin.*] Do the proprietors of the land pay for the water? Yes; the water supply is divided into seventy-two heads, and the country into seventy-two blocks of 1,500 acres each. Each of those blocks gets a head of water, the supply being regulated by iron gauges. The proprietors have to pay for the necessary works to distribute the water over their holdings.

Water rights.

8482. *President.*] How do they acknowledge water rights in New Zealand;—suppose a man at the head of the river wants water does he get priority over the man further down? No; each holder of a block of 1,500 acres gets 1-72nd part of the water flowing in the race.

8483. He only gets his proportion, no matter what his position from the head works may be? Yes.

Effect on river.

8484. How is the river affected? The river from which the water is taken is a tributary of the Waimakiriri, and the head works are not far distant from the junction of the two rivers. There is such an immense body of water in the Waimakiriri River that it is not affected to any appreciable degree by the water which is taken out of the Kowaï River. There are no frontage rights in New Zealand—in selling the land the Government reserve a water frontage to rivers, lakes, and the sea of a chain in width.

Water rights.

8485. But have not the owners of land the Common law right to the water in the rivers. Is one man allowed to divert water from its natural course to the detriment of his neighbours below;—have the Legislature passed any law on the subject? I am not aware whether there is any local law, but I know that a private individual has constructed head works on the Rakia River to take water over his property, and no complaint has been made by people below, but in this case there is always a large body of water running.

8486. *Mr. Murray.*] I suppose that in such a case permission would have to be got from the Government to take the water across the reserve? I do not know. Any man who wishes to take water across a road has to get a license from the Road Board; the license is according to the form which I now hand in. (*Appendix* DD 1.)

Climate.

8487. *President.*] What is the nature of the climate in the Canterbury Plains District? There is a rainfall of about 22 inches in the year; the country suffers very much from dry north-west winds in the summer.

8488. Is it at all like the climate in the interior of New South Wales? I should call it an exceedingly dry climate.

Rainfall.

8489. *Mr. Donkin.*] Is the rainfall distributed over the whole of the year? No; it comes in the winter; in the summer-time there is no rain for four or five months sometimes; there were droughts for three years in succession on these plains, and the oats and wheat would spring up to about 6 or 7 inches in height, and then come out into ear.

Change of climate.

8490. Do you think from your experience in New Zealand that a system of water distribution and irrigation could be carried out in the interior of this Colony? I have had no experience here—I can only explain New Zealand conditions—but I should think so; I see no reason why it should not be done. I may state that since the water has been running down the channels over the Canterbury Plains there has been a change in the climate to a certain extent; the evaporation of the water from the channels makes the atmosphere feel moister.

Trusts.

8491. Do you think that works of the kind should be carried out by local Trusts or otherwise? In this particular case the work was practically carried out by a local Trust; three members of the Selwyn County Council were appointed a Water Races Committee. These gentlemen were residents in the district, and I, as engineer, submitted my suggestions to them, and they submitted them to the Council. The local knowledge of these gentlemen was of immense advantage.

Loans.

8492. Do you think that local Trusts should be formed having power to borrow money from the Government to construct works of the kind, guaranteeing interest on the money so borrowed, or that the works should be carried out by a Central Governmental Department? It depends to a great extent on the districts. I can easily conceive that if a number of small local Trusts were created they might clash with each other, unless there was some central body to govern them; you want local knowledge, and at the same time a central head to produce unity.

Local Trusts.

8493. As a general principle, do you think that the whole matter ought to be kept in the hands of the Government, or that the works should be entrusted to local Trusts under the conditions which I have stated? I think that as a general rule the Government ought to have control over the whole matter, because local jealousies and considerations might upset things. With regard to the works to which I have referred, if the matter had been left in the hands of the people of the district, I doubt whether the works would ever have been carried out. There was great opposition to the scheme at first on the part of people lower down, who were afraid that the water would be monopolized by three or four persons at the head of the channels.

8494. Do you not think that that is a feeling which would disappear when people became acquainted with the advantages of irrigation? It did disappear in this instance; as soon as the people saw the water flowing on to their neighbours' blocks they began to clamour for it too.

8495. Then you think that the objection would only exist in the inception of the works? I think that a combination of local Trusts and Government supervision at the same time would be the best plan, that is to say,

Mr. G. F. Ritso. 25 June, 1885.

say, that a central Board should approve of the borrowing, and perhaps regulate the rating, but the local Boards should be consulted as to the method of carrying out the works in detail; local people must know best what the local requirements are.

8496. Have you any idea as to the cost of preparing land in ordinary cases for irrigation? I have had no experience to guide me on that point. On the Canterbury Plains very little preparation would be needed, as the ground has a gentle slope. I do not know of any instance in which experiments have been made.

Water-rate. 8497. What is the rate charged for the water there? £15 per head of water, each head supplying a block of 1,500 acres with 1-72nd part of the water in the race as near as the supply can be gauged; the water is delivered at any place in the block which the owner thinks most suitable for his purpose. In 1882 the revenue was about £1,000, but since then I have been told that the rate has been increased.

Supply. 8498. *Mr. Murray.*] What volume of water does each head give? 200 gallons per acre per diem, or about 30,000 gallons per block per day.

Licenses. 8499. Then the charge is about £1 per 100 acres? Yes; licenses are also issued at £1 per annum, which entitle people to cart water from the races for domestic purposes.

Supply in Ashburton District. 8500. *President.*] Do you know of any other similar works which have been carried out in New Zealand? In the Ashburton district about 300,000 acres of land have been supplied with water for domestic purposes; the supply is about 20 gallons per acre per diem. About £10,000 was spent on this scheme; there are no falls in connection with it; they run the risk of taking the water down in small channels 4 or 5 feet wide, and running to a certain extent to a gradient according to the contour of the country.

8501. Most of the information which you have given us, I presume, is contained in the pamphlet which you have handed in? No; I am giving you more information, because the pamphlet was written only for the purpose of illustrating the block system and the method of gauging the water. I produce two Acts of Parliament relating to the works. (*Appendices* DD 2 *and* DD 3).

Water districts. 8502. In creating water districts, what is the first step as to defining the boundaries? Maps showing the boundaries of the proposed districts are deposited at the Road Board offices, and the people are invited to inspect them and to state if they have any objection to being included in the districts. If within a certain time no objections are made I think it is assumed that the people consent to the creation of the district.

Poll on rating. 8503. Will the Government proclaim a water district if a certain proportion of the inhabitants in the locality petition for it? I do not know. A poll is taken with respect to the rating.

Frontage reserves. 8504. *Mr. Donkin.*] Is there any law controlling the right to impound water? I do not know.

8505. Are the frontage reserves to the rivers open to the general public? The reserve is a road.

8506. And the proprietors of the adjoining land cannot fence off the water frontage? No.

Supply of Kowai River. 8507. *President.*] Is it snow water which runs in the Kowai River? To a certain extent; there is a range of mountains at the back from which the rivers are fed, and consequently water from melted snow runs in them at times when there are droughts on the plains. I may add that the soil on the Canterbury plains is exceedingly favourable for irrigation, owing to its being well drained, with a substratum of shingle.

8508. *Mr. Donkin.*] But do you not think that if you put much water on to the soil it would wash it away? No, because the country is flat, and there is a foot of good stiff soil resting on a substratum composed of shingle and clay.

Mr. Thomas Willans Conolly called in and examined:—

Mr. T. W. Conolly. 25 June, 1885.

8509. *President.*] You are a licensed surveyor? I am a first-class staff surveyor of New South Wales.

8510. In which part of the Colony? I have been stationed on the Lower Darling. I have had charge of nine counties in the south-west part of the Colony for the last four years.

8511. During that time have the seasons been dry? Very dry all through.

State of Darling. 8512. And the Darling has been very low, has it not? Yes, particularly last year.

Flood. 8513. You have not seen a flood in the Darling? There was one the year that I went there, but it was not very high, and it did not last for a great length of time. I think that it lasted for about two months.

Irrigation. 8514. Do you know of any places in your district where irrigation has been carried on on a small scale? Only in gardens; I know of one or two places.

8515. Successfully? Yes, in growing lucerne.

Pumping. 8516. I suppose that in all the cases the water has been pumped from the rivers or the creeks? From the Darling and Murray in all cases.

Yield. 8517. What was the result as far as yield was concerned? I have no certain knowledge of that; I believe about three cuttings of lucerne per year.

Nature of country. 8518. What is the nature of the country generally? It is clay intermixed with sand; rather a light soil I should call it.

8519. Dry soil? Yes.

8520. And of very little use without water? Very little indeed, and it takes a great deal of water too, because it opens out to such a great extent.

Wells. 8521. Do you know of many wells in the district you have been in? Not very many; the only wells that I know much about are those in the bed of the Great Ana-branch of the Darling; they have had to fall back on them during the last two years.

Source. 8522. Have you any idea as to the source of the water in the bed of the ana-branch? It seems to be an underground current—soakage.

8523. Soakage from the river, the mountains in the distance, or the plains? I think that it is water which is working through, and also water finding a lower level probably from the country around; it is local water—there are no hills of any extent to cause soakage from them.

Depth 8524. At what depth is the water found? From 15 to 50 feet.

Quality. 8525. Is it good water? It is brackish—we have used it in camp occasionally; it is not nice water, but it is good for stock.

8526. You do not think that it is simply river water sinking down? I think it is. I think it is water which has soaked through the clay into the sand when the water has been stored in the ana-branch or running through it; there are several dams in the ana-branch which hold water back for a long time. I fancy that a good deal of the water in the wells is that which has soaked down.

8527. What is the nature of the wells away from the river? They are very salty; all those that I have seen are utterly useless.

8528. Is not the water good for stock? No, they have not been able to use it. I am speaking of the south-western part on the west side of the Darling; on the east side there are wells which are used for stock. Mr. T. W. Conolly.

8529. Does the Darling River channel seem to form a boundary between good and bad water? As far as I have been able to see I think so. 25 June, 1885.

8530. Do you know of any large storage basins in the river, the ana-branch, or the neighbouring country? I have prepared a short report on the ana-branch, which I will read:— Storage basins.

WATER CONSERVATION.—Western District of New South Wales.—A few remarks on the natural water system of the great ana-branch of the Darling River, and the means at present adopted for conservation of flood-waters. Great Ana-Branch.

Sir, Sydney, 24 June, 1885.

I have the honor to submit a few remarks on the natural water system of the great ana-branch of the Darling River and the means at present adopted for conservation of flood-waters.

2. The great ana-branch under ordinary conditions is subject to heavy floods about every seven years, and lesser floods every four years; these floods will cause a strong stream from the Darling River through to the Murray River a distance of 250 miles by the course of creek.

3. At a point on the Darling River about 34 miles below Menindie (that is by road), a cutting has been made which increases the flow from the river; for some distance, in fact almost to its junction with Redbank Creek, the watercourse is very shallow; from Urntah Waterhole, near Popio Creek, the channel is well defined, running into deep permanent water near the Murray River, 12 miles below Wentworth.

4. Rather more than 1,000,000 acres of fair pastoral country is watered by present system of conservation carried out by run lessees. By more efficient means the ana-branch could be rendered more permanent, and with its flood-escape channels, which terminate in large depressions, would water twice that area.

5. The following are the chief flood channels and depressions:—

Popio Creek and Lake.

Popilta Creek and Lake.—Popilta Lake discharges into Twin Lake, and thence by a system of watercourses and lakes to Ricketson Lake, about 25 miles back from the ana-branch.

Stony Creek and Nearie Lake.

Nitchie and Milkengay Creek and Lake.

Warrawenia Lake.

There are numerous other watercourses and depressions which by artificial improvements might be utilized.

The deepest lake is Milkengay, in which 12 feet of water has been impounded in deepest part; its extent is about 4 square miles.

Lake Popilta is more extensive (about 28 square miles) but shallower.

Few of these depressions, though valuable for receiving, are retentive; evaporation and percolation into the sub-stratum of sand are great wasters, but the greatest waste is caused by wind washing the water over the margin into large fissures which open in the clay as the water recedes.

6. The greatest distance of the ana-branch from the river Darling is 40 miles; its course is tortuous and fall very slight, so much so that upwards of six weeks ordinarily elapses before the water runs through.

7. There are four dams of chief importance forming reservoirs in the channel and throwing back water into the principal lakes, viz., "New House" (10 miles below Redbank Creek); the "183," near Milkengay Creek; "Bingoo," near Wilpatera (which dams water back nearly 40 miles by course of creek); and the "Ana-branch Station" dam near the Murray River. These dams are from 8 to 12 feet in height.

8. The cutting alluded to in paragraph 3 is made at right angles to the Darling River, and a rise of over 18 feet is required to cause a flow of water into the ana-branch.

It is worth consideration whether by slightly deepening and widening this cutting by rounding off the upper side to draw the current in, the flow of water may be increased without affecting injuriously any other interest.

9. The importance of this water-supply to a large tract of country west of the Lower Darling cannot be over-estimated, and I would respectfully submit the desirability of detail examination by survey and levelling to find to what extent it may be rendered serviceable in watering country where the rainfall is insufficient to rely upon tanks.

I have, &c.,

T. WILLANS CONOLLY,

Government Surveyor, 1st Class.

8531. I suppose that the dams which you refer to are simply earthen dams? Yes. Dams.

8532. Do they stand well? I do not think that any of them have received more than one flood; but there has been a good deal of trouble in the control of the dams—there has been great jealousy on the part of the people lower down. Control of dams.

8533. But the dams have not given way? Not without good cause for it; in one case a dam was blown up, and that resulted in the other dams being carried away; when the dam was replaced it stood the water very well.

8534. Is it good holding ground generally? The channel is. Holding ground.

8535. Is not the surface country good holding ground? Not in all these large depressions—not in the dry lakes; it seems to be so in the Milkengay Lake.

8536. You say that the principal loss of water is through fissures which have been produced by the heat, and on to which the water is flapped? That is what I mean when I say that the ground is not retentive; the cracks or fissures run right up to the water's edge. Loss of water.

8537. If the soil is kept moist it is retentive enough? Fairly so.

8538. Do you think that the ana-branch of the Darling is capable of storing a large quantity of water? Yes, and also, perhaps, some of the billabongs. Storage capacity of Ana-branch.

8539. Why not in the bed of the Darling? I should not like to say that you could store water there, because there is a strong current in the river at times; it all depends upon whether dams could be made strong enough.

8540. But the ground is retentive? While it is wet.

8541. Do you know of any rocky bars across the river? There are one or two that I know of; there is one at Tarangara, between Pooncarie and Wentworth, and another—I do not know that it has a local name—about half-way between that and Wentworth. Rocky bars.

8542. Do you think that if a proper survey were made, other places could be found where water could be diverted out of the river in flood-time and carried over a large extent of country by cutting away the banks or damming the river so as to raise the water? I think so; the country back from the river being very much depressed, there are large areas of it which are much lower than the river banks; quite close to the banks the country is lower; there is scarcely a creek which runs into the river. Depression.

8543. *Mr. Donkin.*] Do you know Lake Victoria? Yes. Lake Victoria.

8544. Is there a large body of water there now? It is never dry.

8545. It is the most permanent lake in your district? Yes.

8546. What depth of water is there in it when it is full? They say 16 feet. Depth.

8547. Is it filled yearly by the overflow of the Murray? Yes; except on one side it is inclosed by high sand-hills.

8548. Can any large body of water be stored there? Yes, every time that the Murray rises it discharges a vast body of water into it. Storage capacity.

8549.

Mr. T. W. Conolly. 25 June, 1885.

8549. Are any means adopted at present to hold it there? There is a little dam around the mouth of the Rufus River which prevents a certain quantity of water from running out of the lake.

8550. Would it be any advantage to the surrounding country to store a large quantity of water there? I do not think that it would be any advantage to spend any further money there; it is an excellent water supply as it is now; the water cannot be got out, on account of the height of the hills; when the lake is full it is about 10 miles long and 6 miles wide in the widest part.

Irrigation.

8551. Do they irrigate at Moorna, and how do they raise the water? Yes, by engines.

8552. That is at the junction of the ana-branch and the Darling? It is about 8 miles below the junction of the ana-branch and the Murray.

8553. Do they find it successful? They have grown lucerne for some years for cows and horses.

8554. To what extent? About an acre—perhaps half an acre.

8555. Why is it so small;—don't they find it remunerative? I cannot say; I think that they only grow sufficient lucerne for their horses and milch cows; there is plenty of water, but I do not think that they have tried to irrigate to any greater extent; they seem to think that it would not pay to irrigate for sheep farming; at any rate it has not been tried.

Supply in Murray and Darling.

8556. I suppose that there is no limit to the quantity of water which they could use? Practically there is no limit; there is an enormous quantity of water both in the Murray and the Darling which could be used; it is not very high to lift as a rule.

Rainfall.

8557. What has been the average rainfall since you have been there? During the last four years about 9 inches; it was a little over 8½ inches last year, and 9·22 the year before; the average during the last sixteen years has been a little over 11¼ inches.

8558. Do they consider 11 inches sufficient for pastoral purposes? They look on it as a good season if the fall is pretty heavy at a time.

Acres per sheep.

8559. *President.*] How many acres are generally allowed to a sheep there? There is a difference of opinion; I think from what they say that the average is about 7 acres; I cannot speak positively on the subject.

8560. Are the lessees generally opposed to outside interference regarding the water question? I do not think so; I have heard those interested in the ana-branch say that it would be a good thing if it were put under more efficient control.

Filling of lower dams.

8561. I suppose that along the line of the ana-branch they, as a rule, object to the water being utilized and stored above? The arrangement now is that the water is allowed to run through before any of the dams are filled; they usually cut through the top dams to allow the water to pass, and when the lower dams are filled, the cuttings in the upper dams are filled in with sandbags and otherwise, and then they are filled.

Water-rights.

8562. Do you find the people expressing the opinion that there is necessity for legislation regarding water rights? I cannot say that I have heard any such opinion expressed, but I think that the feeling is that they wish the rights to be regulated.

8563. From your own observation do you think that it is necessary? I think it is.

8564. Do you think that much silting would take place if the river were dammed? I should not like to express an opinion on that point; certainly the water is very dirty.

Silt.

8565. Do you notice much silting in the dams in the ana-branch? Not much.

Wells.

8566. *Mr. Donkin.*] You do not know of any wells which have been put down from 1,000 to 2,000 feet in the back country? Nothing beyond 120 feet. I think there was one of this depth on Scotia Blocks, in which salt water was struck. I may say that I have traced the Willandra from where it crosses the Lachlan and the Darling district pastoral boundary, so as to know that it is the same watercourse through to Arumpo. I cannot recollect what the distance is. At Arumpo there is a high sand ridge right across the watercourse, and some people hold that it runs down to Gol Gol Lake, but I was never able to trace it with certainty. Then there is Box Creek, which has a very long course, and which runs into Lake Taila or Benanee.

The Willandra.

Box Creek.

8567. Is the Willandra as large a watercourse as the ana-branch of the Darling for storage purposes? I do not think so; besides, it is very flat. It runs through swamps to a very large extent. Box Creek, I think, would make a good place for storing purposes; it gathers a great deal of the local rains.

8568. *Mr. Murray.*] Have you made any observations as to evaporation? I have not.

WEDNESDAY, 8 *JULY*, 1885.

Present:—

MR. DONKIN, J.P., | MR. GIPPS, C.E.,
MR. FRANKLIN, C.E., | MR. LYNE, M.P.,
MR. M'MORDIE, M.I.C.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Edmund Bignell called in and examined:—

Mr. E. Bignell. 8 July, 1885.

8569. *President.*] Where do you reside? On the Widgeegowara Creek, in Southern Queensland.

8570. Have you resided any length of time in Southern Queensland? From 1864 to 1869.

8571. In what part? On Delalah, about 40 miles from Charleville.

8572. Did you own any station there? Yes, Delalah.

8573. Any other? Not at that time. Since that I have had a station near Cunnamulla.

8574. How long have you lived at Widgeegowara? About ten years.

8575. You have experienced all kinds of seasons? All sorts.

Warrego Floods.

8576. Could you give us any description of the Warrego during flood, as to its width? No; I have never been above Burenda.

8577. In flood-time what extent of water is there in the Warrego? The largest flood I ever saw was at Cunnamulla. The width at Cunnamulla would be about 100 to 120 yards. The channel at Cunnamulla is about 100 yards wide now.

Width.

8578. Does not the water spread out much? No, not there.

Mr. E. Bignell. 8 July, 1885.

8579. What width is it at Delalah Station? About the same. The Warrego from Charleville to Cunnamulla has high banks, from Cunnamulla to Baringun the banks get smaller, below Baringun the channel gets gradually smaller, and in times of flood the water spreads over the country until it reaches the Darling River; in February and March generally, but of late years rains have been more uncertain than formerly. During '65, '66, and '67 we had very little rain; the drought then was more severe than the late one, but the country was then lightly stocked.

Rain.

8580. What is the longest time you have known without the usual rains falling? I saw it in 1867, I think. We had no rain for two years to speak of; it was a much worse drought than this.

8581. You have not known a longer term than two years without fair rains? No, I think that will be about the average of the worst seasons. Two years' drought is the worst I have seen.

Country.

8582. What kind of country is it? What part?

8583. At Delalah? All the frontage is salt-bush like the Murrumbidgee, then above that the mulga.

Soil.

8584. What kind of soil is it at Delalah? Some is red chocolate soil and some black soil.

8585. How does the country run towards your present station? I think it is very similar all the way; you get good and bad patches.

Ana-branches.

8586. Are there many ana-branches? No, very few. The creek which I live on has been supplied once by an overflow from the river, but only once to my knowledge.

8587. In what year? Between eight and nine years ago.

8588. What is the source of that creek in ordinary times? Local rains.

8589. Is the country ridgy at all then? No; at the head it is ridgy.

Dams.

8590. I suppose you have dams? Yes, there are dams on the creek.

8591. Are there any dams on the Warrego? I do not think there are any left—they have all been swept away. You may build them, but they are liable to be washed away, even by moderate floods. There is one at Belalie; the water went round the end of the dam in a by-wash, and cut a fresh channel; a succeeding flood cut this new channel bigger than the river itself; when that was stopped the next flood made a further channel outside. The dam is much higher than the channel.

Width of channel.

8592. *Mr. Franklin.*] What is the width of the channel at Delalah? I should say 100 yards.

Depth.

8593. What is the depth to the bed of the river from the bank level? Between Charleville and Cunnamulla, I should think between 25 and 30 feet.

Embankments.

8594. Have you not put earthwork embankments on that creek? I have never done so; others have.

8595. What was the nature of it? Material taken out and built in.

8596. There was no attempt at making a core? No, but I have seen timber dams put in.

Height of dams.

8597. Were those dams carried to a greater height than the bank of the river? Yes, 4 or 5 feet. The water never went over; the water usually goes over the dams, but not over the wings.

Wings.

8598. Were wings carried out from them? Yes, a long way; I know one nearly half a mile in length at Belalie.

8599. Have you seen these dams full and water running round them? Yes, the one I was speaking of.

8600. And they were safe? Yes, and this dam is safe still.

Failures of dams.

8601. You have known these dams to fail—to be carried away by the water? Yes; I have known these dams to become dry from use and evaporation—also carried away by the water.

Banks of river.

8602. What was the cause of the failure? The nature of the soil in the natural bank of the river—the spread and force of the water. The channel is not wide enough when we have a heavy fall of rain to carry the water off; it spreads and cuts out other creeks and channels.

Damming of the Warrego.

8603. Then, in your opinion, if a proper overshot dam could be constructed it would be of great service? If you could make it stand, but my own experience tells me that you could not make it stand. I do not think you could build a dam on the Warrego that would stand. The channel is not big enough to carry away the water—it undermines the wings, and the earth is soft like sugar.

Back-water.

8604. Suppose the overshot dam could be so designed as to prevent erosion, what back-water would that give you if the dam were 12 feet high? I think it would throw the water back 2 or 3 miles; it depends where you put it.

Fall.

8605. Then you think the country falls in that direction about 4 feet in a mile? I think so.

Overshot dams.

8606. Do you know whether any overshot dams have been constructed north of our boundary? No, they are all in New South Wales, on the Belalie station and lower down.

8607. You are acquainted with overshot dams that have been successful? Yes, I have seen them.

Construction.

8608. Can you give a description of their construction? They are piles in the first instance driven in, then fastened with 2-inch sawn slabs.

8609. *Mr. Gipps.*] Are the slabs perpendicular? No, they are horizontal slabs on perpendicular piles.

8610. Is it a single or a double row of piles? It has been constructed with one line of piles, and there is an apron on which the water falls behind the dam. Some have been constructed with double rows of piles and puddled walls between. Then logs are put for the water to fall on.

8611. How are they fixed? I think they are tumbled in any how. An apron runs down from the top of the dam shooting the water off.

8612. You are not aware that they are fixed to any piles that are driven in? I think not.

8613. Then there is a degree of safety in that simple mode of construction? Yes, I think so.

8614. Do you think them preferable to the earth-work dams? Yes, in a stream like the Warrego.

Silt.

8615. *Mr. Franklin.*] Is there much silt? Yes, in all that country.

8616. *President.*] Would that river be affected much if overshot dams were constructed towards the Darling? I think the people down the river would be short of water very often. It would impound the small floods, and prevent the water from going lower down. Of course when a big flood came it would not matter how many dams there were. Sometimes we only get a little fresh, and if there are no dams we get a few months' supply in the river.

Condamine and Maranora.

8617. Which of the Queensland rivers do you consider is the greatest feeder of the Darling? I think most of the water comes from Toowoomba, the main range, the Condamine and the Maranora.

Heads.

8618. I suppose the heads of these rivers in Queensland is ridgy country? Mountainous country.

Formation.

8619. Do you know what kind of rock they contain? Some of them are granite.

8620. Is there much volanic soil at the heads of the rivers? Yes, a good deal.

8621. You have no idea of the proportion? I have not.

Mr. E. Bignell. 8 July, 1885.

8622. I suppose the country is much like our own hilly country? Yes, much like it. The main range is much like your main range, and the timber on it is similar to the timber there.

8623. The Blue Mountain range is a different rock—a sandstone: Do you know whether there is much sandstone at the head of the rivers? I do not think so; I have never been there; I go by what I have heard; I have been only at one or two places on the range.

8624. Could you point out any dividing line between the mountain country and the flat country? No, I am not so well acquainted with the range as to do that. When you get to Dalby, going to Toowoomba, you begin to meet the Darling Downs.

Darling Downs.

8625. But what is it west of Dalby? Flat country.

8626. Then there is not much range country up there? Not till you get to the main ranges.

8627. But the rain falls principally the other way? Yes, but the Toowoomba water comes this way.

8628. And all beyond that the other way? About 2 miles from the top all the water on the western side comes to the Darling, and the rest goes to Brisbane.

Table-land.

8629. But that is more of a table-land than a range? Yes, between Toowoomba and the top of the range.

8630. From Dalby it is a table-land, and there is not much difference between Dalby and Toowoomba? I do not know.

Head of Warrego.

8631. Do you know anything of the ranges at the head of the Warrego? I have never been very high up any of these creeks.

8632. Do you know whether there is any sandstone country? I do not know.

Percolation.

8633. Has it every struck you that there has been any leakage or percolation of the water coming down the Warrego? I think more than half of it disappears.

8634. Could you point out any spots where this takes place? If you go along the river bed it is dry for months, but you can always find water below.

8635. Have you ever noticed any apparent loss of water when it comes down after a flood? No, I have not.

Wells.

8636. Have you had any experience in sinking for underground water? In well-sinking, yes.

Depth.

8637. What depth do you sink? 216 feet is the farthest I have been.

Quality.

8638. Do you get salt water? Yes. The water I am now using is not thoroughly fresh; you can drink it, however. I have a well 25 feet deep, the water from which I have been using for eight or nine years; it is splendid water.

Supply.

8639. What supply is there? Sufficient for the house and the garden. I should think from 1,500 to 2,000 gallons a day; I do not think that it would give more, but we have not tested it.

Source.

8640. Do you suppose that that comes from a local source? Sometimes I think it is drainage, sometimes I think it is a spring. If we have a flood the water does not rise any higher. I have no doubt that if a very large pump was used it could soon be emptied.

8641. *Mr. Gipps.*] Does it ever rise a little before the rains? No; neither water nor the atmosphere seems to have anything to do with it. We get it in a white drift.

8642. *President.*] If it is not affected by the rains would that not show that the water does not come from a local source? I do not know where it comes from.

Salt water.

8643. In sinking wells do you first strike salt water? Yes, as a rule.

8644. And below you find better water? Yes.

Strata.

8645. Do you get it in a drift? Yes, always; that is the good water.

8646. What kind of rock is it? Ironstone.

8647. Have you any sandstone? Sometimes in draining a core we get something resembling sandstone; Mr. Henderson, hydraulic engineer, says it is not real sandstone.

8648. What thickness of rock do you generally go through? In boring that 216 feet we went through 69 feet of alluvial.

8649. On the surface? Yes, and then it was rock.

8650. You got through the rock into water? Yes, through rock into a drift.

8651. What was the direction of the drift? I could not tell.

Rise.

8652. Does the water rise at all? The first day the water was struck it rose 6 feet over the surface. At sundown it had lowered down to the top of the pipe, and the next day to 40 feet from the surface. It has remained there ever since.*

8653. *Mr. Gipps.*] You never tried boring it again? No.

8654. Does not the fact of the water rising up and going down again indicate that something may have rushed in and stopped it? I do not think so. We have got the stand-pipe in the shaft. We send a man down and he feels about till he finds a pipe and he puts a plug in, then we pump the shaft dry.

Quality of water.

8655. *President.*] Is that good water? Very good. I had 22,000 sheep, fifty cattle, and twenty-six horses there.

Supply.

8656. I suppose that did not exhaust it? It never lowered it.

8657. You have wells at certain distances? If I put up a paddock I estimate where I ought to have wells to suit the sheep; wherever I decide upon I put the well down, and chance whether I shall get the water—there are no indications.

8658. In this particular well you went through 60 feet of alluvial? I bored down with a diamond drill, then tube it.

Tubing.

8659. Do you ever try to tube to the surface after the water has come into the well? Yes; it will never rise in the shaft.

8660. The effect is the same in all these wells? Yes.

8661. In the first instance the water comes over your heads? No; in none of the others did it ever rise to the surface.

8662. They do not rise? Yes; in every well I have the water is about 40 feet.

Source.

8663. What is your impression as to the cause of the water sinking in the manner you have described after having come up with so much force? I do not think the level of the source is high enough to make it rise to the surface.

8664. But it did when you first struck it? I think that was through its being suddenly let loose. My impression is that the water comes from the Rockhampton Range. 8665.

* Note (*on revision*):—Before commencing to bore we sink a shaft through the alluvial to the rock, then bore from the middle of the shaft, and the stand-pipe remains there. We send a man down the shaft occasionally; when he reaches the pipe he puts a plug in it, which remains till all the water is pumped out of the shaft; when the plug is removed we know the flow of water.—E.B

Mr. E. Bignell. 8 July, 1885.

8665. You think that the water in the five wells is from other sources? Yes.
8666. Have you sunk deeper to try to get artesian water? No; but I believe there is any quantity of water.
8667. All these wells are on the lower run? Yes; on Widgeegowara.
8668. Have you any on the Delalah Run? No; Delalah has not been mine for several years past.
8669. Have you ever tried to get water on that run? No.
8670. Do you know of any outcrop of sandstone? No.
8671. The natural theory would be that, so far as the rock you have spoken of continues, you will get the water underneath? Yes. As soon as I saw the core I was sure that I should find water, because it was so similar to the core in the first well.
8672. Do you find that the water extends any distance across the country? No; the wells are in different positions.
8673. About what breadth of country do these wells cover, east and west? A strip about 5 miles across.
8674. And you have such confidence in finding water that you simply select the most suitable spot and sink? Yes.
8675. Have you failed in any case? I have got water in all cases—in some not so good as in others.
8676. I suppose you have no theory as to the water leaking from the Warrego? No, none at all.

Mud-springs.

8677. Are there any mud-springs? Not in my country.
8678. Do you know of any? Yes; there is the Tago, south-east of the Widgeegowara Creek, and near the border of New South Wales; there is another called Towery, 4 or 5 miles from Tago.
8679. Do you know from hearsay whether there are any number of springs anywhere east or west of the Warrego? On the Paroo there are plenty; you get a number in one patch; then you go a long way before you get another. The Tago is 9 or 10 acres of springs. At Towery they put down an auger right through the centre of the springs, and tube, and they have an artesian supply; it rises about 15 feet above the surface.
8680. What supply is there? I think about 3,000 gallons a day; there may be more, but I do not think there is.
8681. There is a supply of about 120 gallons an hour? I should think that is about it.

The Paroo.

8682. Do you know much about the Paroo country near the ranges? I have been on the top of the ranges.
8683. What is the nature of the country? Rocky and ridgy, with mulga timber.
8684. What kind of rock is it? Rotten ironstone.
8685. Have you had any experience of water-sinking there? I never tried it; in some places people have wells there.
8686. Have they any artesian supply? No.

The Warrego natural basins.

8687. *Mr. Franklin.*] Do you know if any line of action could be taken for the conservation of water on the lower part of the Warrego, are there any natural basins or billabongs? No, Nature has given you nothing.

Depressions.

8688. No depressions? There are some, but not sufficient to do any good.

Overshot dams.

8689. Do you think it would influence the stream lower down if some overshot dams were constructed by which we might regulate from behind the supply for the lower part of the country; if overshot dams were constructed with sluices fixed in them, might we not fill them in times of flood? Immediately after a flood there is plenty of water, but if you kept the water there it would disappear to a certain level.
8690. By evaporation? By passing underneath. If you had 20 feet of water at the head of your dam it would soon fall to the same level that it is at now; I think it has some way of escape.
8691. If we were to make substantial dams the water would subside by evaporation and soakage? I think so.
8692. As a matter of fact, you cannot keep permanent water now? Only in the natural bed of the stream. If you raised the water 1 foot above its present level I believe it would go away; I think there are leakages in the soil.
8693. There are no natural lakes there that might be enlarged? No, none.

Diversion.

8694. *President.*] Do you know of any place where the water could be diverted by means of a canal or an embankment into a depression away from the river? It was my intention before I commenced boring to carry the water into our own creek, and we had the levels taken by a practical man, but found that we could not do it.
8695. Does the country rise? Yes.

Evaporation.

8696. Have you had any experience as to the evaporation in that part of the country? Only in a casual way.
8697. You can give no reliable information on the subject? No.
8698. I think from what you said just now you may be able to give some information as to water being diverted from the various channels into depressions? On the Warrego?
8699. Yes? Yes, but I do not thoroughly know the lower part of the Warrego.

Current.

8700. *Mr. Donkin.*] Is the current very strong in the Warrego in times of flood? No, not very rapid; it is a sluggish stream. The biggest flood I ever remember I think took three weeks to come from Charleville to Cunnamulla.
8701. *President.*] What distance is that? It will be 120 miles.
8702. In coming that distance I suppose there would be very great loss? It had to fill up all the holes and billabongs.
8703. *Mr. Donkin.*] You said it did not spread much? It did not.
8704. But it spread at Cunnamulla Creek? Yes.

Cost of wells.

8705. Speaking of diamond drills, what do you calculate the wells have cost you;—the deepest you said was 216 feet? It depends upon what point you commence with your estimate.
8706. What do you consider to be the cost per foot, taking the average? I can tell you to a shilling what the cost will be after the machinery is erected. There is the cost of one engineer boring for fifteen days, at £5 5s. a week and his rations—say altogether £6 a week. A man to drive the engine, £2 a week and his rations. Two men are kept to draw the rods and lower them; their wages would be 30s. a week each and rations; say £4 altogether. Then a cook at 25s. a week and rations, and a man to draw water and feed the engine—sometimes two are employed—it depends upon the distance you have to draw the water. We had excavations made to catch water. I put down 25s. a week for draught horses, making £2 with rations, and you may put down £4 for firewood for the whole work.

8707.

Mr. E. Bignell. 8 July, 1885.

8707. I want to ascertain what it would cost to contract for the sinking of a well? You have to allow for two horses, and you could not get them under £1 a day, but you would not have to pay for the driver. £1 a day for the horses is the best way to get at it.

8708. There is the tubing and the carriage? Well, it depends upon what sized bore you use; ours is 5-inch bore, Glasgow tubing.

8709. What is the width of your well? 5 feet by 2 feet 6 inches.

8710. What is the bore? 5 inches. It is more, but it is done with a 5-inch tube. That will cost 4s. a foot. I paid 3s. 6d. for it.

8711. That is £27 a week for labour, £43 for tubing, £4 for wood, and then there is your own superintendence? Yes.

8712. That will be about £35 a week as the cost of the work? Yes, but there is 60 feet to come off for alluvial.

8713. *President.*] That is about £113 for 156 feet of sinking with the diamond drill?

8714. *Mr. Franklin.*] Could you not submit an appendix giving all particulars? If you are not in a hurry you could obtain all the particulars from Mr. Henderson—he will give you the whole thing.

8715. What would you do it for per foot if you were employed to sink a well? You would have to take into consideration the wear and tear of plant.

8716. *Mr. Donkin.*] Would you do it for £1 a foot? I think that was the offer, but it was to bore on my own land.

8717. *President.*] If a person goes in for sinking wells he will have his plant there, and the interest on the cost of the plant has to be considered; to charge every well with the cost of bringing the plant from Brisbane or Sydney would not be fair;—would not £1 a foot be a fair average? In a country like ours he would have to shift his plant very often.

8718. Do you think that if a contractor undertook to sink for artesian water, he could do it cheaper than sinking for the shallow? Yes, you can sink 2,000 feet much cheaper than you can sink 500 feet, because you do not require to remove your machinery. The moving of the machinery involves a large expense. There is no difficulty in boring through rock; 5 feet of drift is worse than 50 feet of rock.

8719. *President.*] The Government charge £10 a week for wear and tear, and this amount with payment, or three men and the other expenses, would make £26 a week.

Rainfall. 8720. *Mr. Gipps.*] What is the general character of the rainfall? It comes in heavy storms—thunder-storms as a rule; it comes from the west.

Floods. 8721. Does it produce floods instantly? Next morning.

8722. High floods? It would depend entirely upon the state of the ground and the character of the rain. No fall of less than 3 inches in our district will cause a flood, and it must come all at once; if it takes a week or a fortnight to fall it will be of little good for supplying water.

Dews. 8723. Have you any dews? Very seldom; we may have occasionally just after a rain.

Winds. 8724. What are the prevalent winds? They come chiefly from the westward.

8725. Summer and winter? Yes, but we get very little wind there at all. I purchased a windmill and I have seen it stand for months without revolving.

Tanks. 8726. Have you any tanks? I have twelve or fifteen large ones.

8727. Of what dimensions? 8,000 to 15,000 yards. I have one about 16,000 yards.

Depth. 8728. What depth? 14 feet 8 inches is about our deepest.

8729. For what purposes do you use them? For sheep and cattle.

Supply. 8730. How many sheep and cattle do you water in the largest one? I think 6,000 sheep is plenty. It is according to the paddock. It does not matter how large the tank is, the grass will not last as long as the water if you put more than that number of sheep on it.

8731. Do the tanks ever get empty? Yes, very often.

8732. The largest one? Yes.

8733. In how many months? I should not like to be compelled to put more than 6,500 or 7,000 sheep on a tank. The last 2 feet off the bottom is lost after the first season or two.

Silt. 8734. Then you have no silt tank? Yes, but a certain amount of silt will always come in off the batter.

Holding ground. 8735. Is it good holding ground? Very good.

Evaporation. 8736. Do you lose much by evaporation? Very much, I think.

8737. You have never measured it? No.

Height of flood 8738. What was the height of the highest flood in the Warrego? I know that at a station just past Cunnamulla the water has been right up to the verandah. It must have been 50 feet high.

Current. 8739. Is the current very rapid? No.

Witness: I can get you from the station a full account of the cost of plant, and the cost of boring and everything.

President: Your evidence will be sent to you, and those particulars can be added.

Witness: Through the use of the drill I have saved my sheep during the late drought and have had a good lambing, whilst other stations have lost heavily. We have from nine to ten months without a drop of surface water on the land at all.

THURSDAY, 9 JULY, 1885.

Present:—

MR. DONKIN, J.P., | MR. FRANKLIN, C.E.,
MR. GIPPS, C.E., | MR. M'MORDIE, M.I.C.E.,
MR. MURRAY, M.P.

F. A. FRANKLIN, ESQ., C.E., IN THE CHAIR.

Mr. W. J. Hanna called in and examined:—

Mr. W. J. Hanna. 9 July, 1885.

8740. *Chairman.*] You are the Road Superintendent of the North-western District? Of the Western District.

8741. Your district is bisected by the 144th meridian of longitude, is it not? Yes.

8742. That goes nearly through Wilcannia? About half a degree to the east of Wilcannia.

Mr. W. J. Hanna. 9 July, 1885.

8743. In seeking information from you how far may we safely go to the eastward of Wilcannia up the Darling River? I have not been much to the eastward of Wilcannia. Information so far has been obtained when travelling over the roads in my charge.
8744. To what distance up the river above Wilcannia? I have not been far up the river—about 20 miles I suppose.
8745. Below that I suppose you are intimately acquainted with the features of the country, both on the river and in the back of the country? No, not in the back country.
8746. In which direction have you roads under your supervision to the westward of Wilcannia? From Wilcannia to Thakaringa.
8747. How long have you been resident in that part of the country as road superintendent? Two years.
8748. What have the seasons been during those two years—have they been ordinary seasons, or seasons of great drought? The summer of '83–'84 was one of the worst that has occurred within the memory of the oldest inhabitant, causing enormous losses of stock throughout the district. From June, '84, till January, '85, the rainfall, although light, was sufficient to prevent further loss. Heavy rain on the latter date filled all tanks and natural waterholes, producing abundance of feed from the Queensland border to about 20 miles below Menindie. Seasons.
8749. What was the state of the roads during that time? During the summer before last they were almost impassable, owing to want of feed and water. Roads.
8750. The great traffic to the Silverton mines had not commenced then? Not at that time; it is only during the last twelve or eighteen months that the traffic has increased so much. Traffic.
8751. And it has increased to a very great extent I suppose? Yes.
8752. What are the natural sources of water-supply on the road between Wilcannia and Silverton? There are no natural supplies worth mentioning except at Stephens and Yancowinna Creeks. The former, which is soakage-water, might be considered permanent for wheel traffic, and for the same purpose the waterhole in Yancowinna Creek would last from eight to nine months in a good season. Water supply.
8753. How far is that from Wilcannia? About 150 miles.
8754. What means have been adopted by the Government to provide water along the road for the purpose of meeting the requirements of the increased traffic? The Mines Department is boring at Netallie, Lewis's Tank, and other places. Borings.
8755. At what intervals along the road are they proposing to provide a permanent supply of water? I do not know.
8756. In the meantime what means are resorted to for providing water for stock and travellers? None beyond what I have mentioned. Besides Stephens and Yancowinna Creeks referred to there is permanent water at Lewis's Tanks, 8 miles west of Calker's Well, but that is private property. Lewis's Tanks.
8757. How is the water obtained;—is there a dam in the Yancowinna Creek? No; there is a natural waterhole in the bed of the creek. The Mines Department is boring at Nettalie, Salt-bush Flat, and Lewis's Tank. Waterhole.
8758. Do you know whether any successful results have been met with in the bores? Salt water was struck in the first bore, near Netallie, but they have gone through it and are now in hope of getting good water. The depth I think is over 300 feet. Salt water.
8759. None of the works are complete yet? None.
8760. *Mr. Gipps.*] Are they boring through rock or through the ordinary drift? Through drift in the Netallie bore. They have got stock water at Salt-bush Flat, about 20 miles from Wilcannia. Strata.
8761. *Chairman.*] Is the road between Wilcannia and Silverton bisected by any well-defined course at all? Yancowinna and Stephens Creeks are the principal ones, but there are numerous watercourses of more or less importance.
8762. Are you aware whether any works have been constructed on those creeks to retain the storm-water? There are none. Storm-water.
8763. Has it ever occurred to you whether it would be possible to make dams for the storage of water in those creeks? Stephens Creek I consider is too shallow, and the bed too sandy. In Yancowinna Creek, close to the road, there is a site for a dam, but the risk from floods would be too great. Storage in creeks.
8764. The risk to an earthwork dam? Yes.
8765. What is the width and what the depth of the creek? Approximate measurements at the place I allude to are: south bank, 12 feet; north bank, 8 feet; top width, 50 feet; bottom width, 13 feet. Yancowinna Creek.
8766. Supposing that there is a slight fall in the creek, to what distance would a 10-feet over-shot dam back the water? About 120 chains. Fall.
8767. You do not know whether any steps have been taken, or suggestions made, for damming those creeks you have mentioned? I am not aware that anything has been done. In a report furnished to the Engineer-in-Chief for Roads with reference to water supply between Wilcannia and Thackaringa, I recommended a well at Yancowinna Creek in preference to a dam, as there is a very fair prospect of obtaining good stock water by sinking. Damming of creeks.
8768. The well you proposed would be an ordinary well I suppose? Yes, with tank and troughing. Well
8769. Do you know whether your report has been favourably received? No; the watering of the road was taken over shortly afterwards by the Mines Department, and sites now adopted were chosen, I presume, by their officers.
8770. Can you give us any information about other parts of that road, where it has occurred to you that works might be carried out to conserve water for keeping open the communication with the Silverton mines? The country, on the whole, is well adapted for the conservation of surface water. There are good and extensive catchment areas, most of which will shed a large proportion of rainfall. At Yancowinna Creek and Salt-bush Flat tank sites could also be found, but there being a good prospect of obtaining stock water by sinking, and as the country at these places is rather flat, wells were recommended. For other stages I would be in favour of tanks; that is, up to Mount Gipps, which was as far as I was able to report. It was during the very dry summer, and I was not able to get right through. Conservation of surface water.
8771. From your general knowledge of the lower part of the Darling can you say in which way the drainage lines tend to the northward and westward of the river? I cannot.
8772. Have you ever observed that the bank of the river is higher than the country away to the northward and westward? Yes, I have noticed that in several places, and also that one bank is nearly always higher than the other. Darling banks.

Mr. W. J. Hanna. 9 July, 1885.

8773. But have you any particular reason for knowing that there is a fall away of drainage water from floods into the country west of the Darling? Yes, and also on the east side; the ana-branches and lakes into which water flows from the river, when in flood, clearly prove this.

Natural depressions.

8774. And do you know of any large natural depressions, such as lakes, or dry beds of lakes, on the banks of the river? Yes, a large number.

Lakes.

8775. How frequently do they occur below Wilcannia, and at what distance? The following are the approximate distances in miles, from Wilcannia, of some of the principal lakes that are filled by the river when in flood:—Woytchugga, 5; Matta, 70; Teryaweynya, 66; Byyi, 79; Pamamaroo, 82; Lakes Cawndilla and Tandou, about 8 and 18 miles respectively from Menindie. As the river falls the flood-waters recede, leaving behind a comparatively small body of water, which, in some cases, the evaporation of a summer and absorption will completely dry up.

Diversion from lakes.

8776. What would be the advantage if the flood-waters could be retained in those lakes as reservoirs—could the water be utilized? It could be conducted to other parts of the country by means of drains or canals.

8777. Would the natural fall of the country permit of the distribution of the water by gravitation? I do not think the flood-water could be profitably used for irrigation purposes, but it could be drawn from the lakes into natural depressions, creeks, and billabongs.

8778. But taking the natural fall of the river, if you stored the water to the highest point possible in the lakes, could it not be discharged on the line of the river? Yes, that would be quite practicable, and productive of much good, if the supply from the river could be kept up; but a high flood seldom occurs, and does not remain more than two or three days stationary, so that the inland current would soon be cut off.

8779. By decreasing the fall we have in the river bed, we could discharge that water into the lower country towards the counties of Windeyer and Tara, towards Wentworth? Yes, but to maintain a continuous supply it would be necessary, I think, to put in a lock or weir, or tap the river at a much higher level.

Area of lakes.

8780. I believe those lakes are of very large area? Very large, but generally speaking they are not very deep; some of them contain no water except while the river is in flood.

8781. And you have not had your attention specially directed to the subject of watering except on the line of route? In March last I received a letter from the Commissioner and Engineer-in-Chief for Roads, asking me to collect as much information as possible with reference to the flow and storage of flood-waters throughout the district, and, if my ordinary duties permitted, to inspect some of the lakes and other places where important information could be obtained. This report I have not yet been able to furnish, owing to pressure of work.

Country from Wilcannia to Wentworth.

8782. Are you acquainted with the country on the southern side of the river Darling? Not personally, as my travels are confined to the roads. Along the course of the river from Wilcannia to Wentworth the country consists of what is known as the "red soil" and "black soil," with occasional sand-hills.

8783. But I suppose you know the Tallywalka? Yes.

The Tallywalka.

8784. The Tallywalka is rather large in area: what is its general condition? It is always dry except in flood-time.

8785. In flood-time I suppose it is fully charged with flood-water, which recedes with the receding flood-waters of the river? Yes; when the river is at a height of 28 feet at Wilcannia the water will flow in the Tallywalka Creek.

8786. And it eventually discharges into the Darling again? It would if the water remained at a high level for a sufficient length of time, but I believe there is a dam across the Tallywalka Creek which diverts the water from the main channel southward for the purpose of filling the Teryaweynya and other lakes. When these lakes are full, or the water rises to a fixed height, it is, by virtue of an agreement made by those interested in the work, allowed to flow past and discharge into the river about 5 miles below Menindie.

Terraweynya Lake.

8787. What is the natural drainage of that water at the overflow to the Terraweynya Lake—in which direction would it naturally flow from there? I cannot say; I have not been down there.

8788. Do you know whether, when that lake is filled, the water is considered permanent? It is not permanent, but would last for four or five years.

8789. Is it shallow? Yes, in its present state, but from what I have heard I am inclined to think that, by a comparatively small expenditure, the storage capacity here and in some other lakes can be largely increased. All the water that came down in the last flood, which was the highest that has been known there for some time, never went past the dam.

Works.

8790. As the fall of the Tallywalka appears to be in the same ratio as that of the country in which it is situated, do you think it is possible to construct works by means of which the water might be retained in time of flood and utilized for keeping the lakes permanently filled, advantage being taken of the natural course of the creek as a canal? Works could be easily constructed in the creek to retain the flood-water, but the quantity of water thus impounded would be of very little service in keeping the lakes permanently filled, owing to their immense surface area. If the fall at the head of Tallywalka Creek would admit of being lowered, a low weir could be put across the river, to take advantage of freshes that frequently occur, but from which no benefit is derived. In connection with this I think it is worth considering the advisability of constructing a lock at Wilcannia, where there is a rock foundation on one side, stretching nearly across the bed of the river. On this subject, however, I cannot at present enter, but shall forward further information, if required, after inspecting.

8791. But in any case there would have to be regulating headworks to admit and impound the water? Yes, especially when the lakes and river-bed at inlet are on the same level or nearly so.

8792. Then, of course, the Tallywalka would have to be treated by levels to ascertain in what way the water should be dammed at intervals, so as to keep it constantly in the creeks? Yes.

8793. You are not aware of anything that has ever been done to test the possibility of doing that? Nothing has been done that I am aware of.

8794. I suppose you are not aware of the fall of the Darling per mile? No, but I believe it is accurately known.

8795. There is some proposal at Wilcannia for putting low crest weirs in the Darling? Yes.

Weirs in the Darling.

8796. Have you ever formed an opinion as to what the result would be if overshot weirs were built at a low level in the Darling? The river of course would be unnavigable, but the water which now flows into the ocean would be diverted through other channels to fill the lakes already referred to with a permanent supply of water, and increase the value of a large area of country.

8797.

Mr. W. J. Hanna. 9 July, 1885.

8797. *Mr. Donkin.*] Do steamers run up to Wilcannia now? Yes; there were twenty-seven up on the last rise, but the river at the present time is not more than a foot or 18 inches deep, and therefore unnavigable throughout its whole course. Flood-water from the Murray backs up the Darling about 20 miles.

8798. *Chairman.*] It is proposed, I believe, to put locks in the river? Yes; a company was formed some time ago for that purpose.

Loss in locks.

8799. Do you know if any calculation has ever been made as to the waste of water in taking the steamers through the locks, and as to how the supply can be kept up? Not that I am aware of; I presume the loss would be made up by the water coming down.

8800. Assuming that there is always a sufficient quantity running? Yes.

8801. And do you think that a sufficient quantity of water comes down the Darling at Wilcannia to make good the loss that would occur if the navigation were kept open, taking into consideration the length of the steamers and barges and the distance between the lock gates? There might not be sufficient to make up the loss in a very dry season.

8802. Without provision being made higher up the river to keep up the supply? Yes. Taking traffic into account, the cost of impounding water for this purpose would be too expensive. With carefully constructed locks it could be safely calculated, I think, that the river would be navigable at least nine months in the year.

8803. But you know there would be a great slip of water at the lower lock if the river was constantly used for navigation purposes? Yes. The river being closed for two or three months in the year would cause very little inconvenience, but I think it is doubtful if such would be the case unless during a drought or exceptionally bad season.

Irrigation and navigation.

8804. By which means do you think the interests and progress of the Colony would be best advanced—by conserving the water for distribution over the country for irrigation and other purposes, or by carrying out works for keeping the river open for navigation? Most decidedly for irrigation, but I would add that locks would suit both purposes.

Railway.

8805. And a railway would answer all the purposes of communication with Wilcannia? Yes. That, however, is an opinion that very few will indorse in the Wilcannia district.

8806. But it would be most beneficial to the country at large? It would.

The Paroo.

8807. Do you know the Paroo River? I have travelled up and down it occasionally, but have not spent any time in examining it.

8808. You have not had time to study it throughout its course from the borders of Queensland? No.

8809. Do you know its terminal point where it ceases to be a defined creek or river? It is very hard to say where it ceases; except after heavy rains it is never running.

Dams.

8810. What means have been adopted by the lessees there to retain the water for stock purposes? They have made some dams above Wanaaring, but I have not seen them.

Water flowing up the Paroo. Site for dam.

8811. Then you do not know the nature of the country, so as to say whether it is possible to dam the lower part of the Paroo and convey the water some distance from the river? When the river at Wilcannia rises to 30 feet the flood-water will flow up the Paroo channel about 50 miles, filling Copago Lake, which is approximately $2\frac{1}{2}$ by $1\frac{1}{2}$ miles, and other natural depressions. About 9 miles from Wilcannia there seems to be a good site for a dam. The work would be comparatively inexpensive, and conserve a large body of water. This dam could be constructed with sluices to admit the flood-water from the river and prevent its return. It would also impound the flood-water coming down the Paroo, and thus suit a double purpose. From this and similar reservoirs I am inclined to think that the water can be drawn (by gravitation) for storage in other places.

Outlet of the Paroo.

8812. Then the Paroo, where it enters the Darling, is a well-defined creek: there is no evidence of that on the map, which shows that the Paroo ends in a large swamp? There is a creek which enters the river, and into which I think the flood-water from the Paroo would flow, but it never did so until the last flood, which was the highest that has ever been known. The creek which enters the Darling a few miles above Wilcannia may be set down as the outlet of the Paroo River.

Paroo flow.

8813. *Mr. Gipps.*] Does the Paroo ever flow into the Darling in a continuous stream? The Paroo was never known to flow into the Darling prior to the flood in January last.

8814. Did it do so then? Yes.

Kalyanka Creek.

8815. *Mr. Donkin.*] Is that the Kalyanka Creek? Yes.

8816. *Chairman.*] That creek you take to be the outlet of the Paroo to the river Darling? I believe it is. The water was never known to flow there before.

8817. The water simply recedes with the flood, and no attempt is made to check it or conserve it? None.

Cobham, Yantara and Salt Lakes.

8818. Have you made any observations with regard to Cobham Lake, the Yantara and Salt Lakes, as to their general condition in dry weather? Yes; these lakes were quite dry before the January flood. Cobham Lake contains at present about 26 feet of water. There are four or five creeks flowing into it, but, so far as I am aware, it has no outlet—it seems to be a basin. Cobham, Yantara, and Salt Lakes are all full.

8819. Why is the Salt Lake so called;—does it at any time become saline? Yes; when the water falls to a depth of about a foot it becomes quite salt.

8820. Then I suppose it is not suitable for stock or any other purpose? Not then.

Cobham Lake extent.

8821. What is the extent of the Cobham Lake? From 1,600 to 1,700 acres. During the summer of 1883–4 there was a radius of 20 or 30 feet on north side of the lake within which good water, fit for domestic use, was found at a depth of about 10 feet, but beyond that the water was as salt as the sea.

8822. What is about the average depth? The deepest part is about 26 feet.

8823. What would you take the average to be? From 15 to 17 feet.

8824. So that we may calculate the area you have given by about 15 feet of depth for the contents of the water? Yes.

8825. Can the water be discharged from the lake by gravitation? I do not think so; there is no outlet.

8826. Do you think that if extended levels were taken in the line of the Darling the increasing fall of the ground might give a discharge from that body of water? I do not think water can be taken from the lake by gravitation, and, if practicable, it is very doubtful if that course would be judicious. The supply is too limited, the locality unsuitable, and the ground too porous. The amount required for constructing works to drain water from the lake (if found practicable) for distribution would be better expended on storage works.

Mr. W. J. Hanna. 9 July, 1885.

8827. How far is the Cobham Lake situated back from the river? About 130 miles from Wilcannia in a direct line, or 150 by road.

8828. In the line of the river? That would be about its distance from the river. The road is at about right angles to the river.

8829. And the water is at present serviceable for people travelling on the road? Yes; and will be for four years.

8830. You consider that it will be permanent for four years? Yes.

8831. *Mr. M'Mordie.*] Do you mean that it would be permanent for four years without any rainfall during the period? I am allowing for an ordinary rainfall—say 6 to 7 inches of rain in the year.

Yantara Lake. 8832. *Chairman.*] Are the Yantara and Salt Lakes also of considerable magnitude? Yes, they are both large; the former covers an area of 8,000 to 9,000 acres.

8833. And of great depth? I cannot say what depth.

Cobham Lake. 8834. *Mr. Donkin.*] Was Cobham Lake dry the summer before last? Yes; it was dry for years.

8835. *Chairman.*] And it is an unusual thing to find it so fully charged with water? Yes.

8836. You do not know whether it has ever been considered practicable to use the water of the lake by means of gravitation? I do not think it has ever been tried—I do not think it could be done; the lake is surrounded by high ground, in the lowest part about 20 feet above the bed of the lake.

8837. *Mr. Gipps.*] Is there any drainage channel from the lake? None that I am aware of.

Watershed. 8838. What is its watershed? I cannot say how far the watershed extends. The creeks that flow into Cobham Lake are Mount Brown, Evelyn, Yarramurtie, Wonaminta, and Burr Creeks.

8839. *Chairman.*] Then you are not sufficiently acquainted with the locality to say whether it is possible to find a depressed part in the surrounding ridges where, by a moderate cutting, the water could be taken through? No, I have not examined the country surrounding the lake with this object, and cannot therefore say definitely that the distribution of water from the lake by gravitation is impossible, but in my opinion the advantages to be gained would not justify the expenditure.

Lakes filled from Darling. 8840. Do you think it would be possible, by raising the head of the Darling, to keep the lakes constantly replenished by bringing the water over the surface of the country? I do not think you could bring the water from the Darling into those lakes.

8841. *Mr. Donkin.*] The fall is towards the Darling, is it not? I think the fall from Cobham would be to the Darling—say about Wilcannia.

8842. The Paroo water could not be diverted in that direction, could it? I do not think so. If any water could be diverted into these lakes it would be from the Paroo, but I am doubtful if it could be.

8843. Do you know what height Cobham Lake is above the sea? No.

Levels. 8844. *Chairman.*] And you have no road levels connecting the Darling with Cobham Lake? No.

8845. *Mr. Donkin.*] Have any levels ever been taken there from the Darling? I do not think so.

8846. You do not take heights with the aneroid? No, I have never found it necessary.

8847. *Mr. M'Mordie.*] Have you any road levels through you district? None. Macadamized roads, unless in a few exceptional places, are not required—simply clearing; it is all level country.

Conservation in billabongs. 8848. *Chairman.*] In the part of the Darling that you are best acquainted with do you know if there are many old points of the river, such as billabongs or depressions, preserving something like the sectional area of the river, but now grassed over? I have observed some below Menindie.

8849. Are they of any great extent? Not very great. I have only seen them when passing in the coach.

8850. Did it ever occur to you that the flood-waters might be retained in them with advantage? Oh yes, the flood-water could be stored by constructing a dam with sluices at the entrance to the Darling, or a dam at the outlet and a dam with sluices at the inlet, as the case might be.

8851. Do you think that they are of such extent and of such frequent occurrence as to materially ease the floods? No, not to any extent.

8852. Have you formed any opinion at all as to how the storage in those lakes immediately on the banks of the river might be increased, by raising levées or by any other means? Dams with sluices or similar regulating works would, I think, be found to be the most suitable. The storage capacity in some cases could probably be further increased as proposed, but this course would check the outflow to other reservoirs, or necessitate the construction of additional works.

8853. That is to regulate the water flowing in from the river and to shut it in? Yes, that would be quite practicable in many creeks.

Benefits. 8854. For whose benefit would the water be conserved? It would be a benefit to the Colony at large, as the country would be permanently improved. The carrying capability being increased, the lessees could afford to pay a corresponding increase in rental.

Height of floods at lakes. 8855. Do you know what is the relative height of an ordinary flood above the present level of these lakes—could a greater height be obtained by building a continuous levée around them? I could not say. I have never seen any of them, but the openings to the river would be very suitable places for works to conserve water.

8856. And you believe that by a system of locking by sluices the water could be retained in most of those depressions and lakes so as to be of benefit to the country? Yes, and inexpensive when compared with the benefits to be obtained.

Building material. 8857. What kind of material would be best for that part of the country in the absence of stone, for the construction of those works? Timber. I do not think the cost would exceed 25s. per 100 superficial feet if brought up by water.

8858. You would depend on water-carried timber for any works of that kind? Yes.

8859. *Mr. Murray.*] That is sawn timber? Yes.

8860. Would not rough squared timber be as suitable? Hewn timber would be equally suitable for the greater portion of these works, but it is doubtful if it would be less expensive, owing to the cost of labour. In some parts of the district for timber locally sawn £4 per hundred has been paid.

River register at Wilcannia. 8861. *Chairman.*] Have you made any observations at Wilcannia as to the height of the river at all seasons of the year? I have not, but I think there is a register kept.

8862. Do you think it is reliable? I believe it is.

8863. Do you know of any parts of the bed of the Darling, in the vicinity of Wilcannia, where an overshot weir could be built—any sort of strata that is different from the general strata of that country? Yes, there

Bar at Wilcannia. is a bar of rock at Wilcannia which stretches nearly across the river from the Wilcannia side.

8864. What do you estimate its angle of dip to be? It is nearly horizontal.

8865. *Mr. Gipps.*] It is bed-rock, is it not? Yes; it would be about 25 or 30 feet below the surface. Mr. W. J. Hanna.
8866. What is the character of the rock? I have not been down to it.
8867. *Chairman.*] Have you formed any opinion as to the hydraulic discharge—that is, the proportion of a 3-inch or inch rainfall that would discharge into the river after an ordinary dry season? That is a difficult question to answer—it depends entirely on how the rain falls; for instance, you might have 6 inches of rain in the year, but it might fall in such a way that very little, if any, would reach the river. 9 July, 1885. Discharge.
8868. Take a steady downpour for twenty-four hours during which you get 6 inches of rain, making allowance for the absorption of that part of the country? From a fall like that I think about 30 per cent. would reach the river.
8869. What is the nature of the country? Black and red soil, and occasionally sand-ridges. Country.
8870. Have you ever noticed particularly after an inch and a half fall of rain whether all the creeks were running? An inch of rain will make all creeks (excepting the larger ones) run. Creeks running.
8871. And how long a time would elapse before the creeks subsided again? I could not say; I have not taken particular notice.
8872. *Mr. Gipps.*] What is the area of Lake Woytchugga—one of the lakes which could be filled from the river? I could not say. Lake Woytchugga.
8873. Can you give it approximately? The approximate area might be set down at 1,500 acres. Area.
8874. What is about the average depth? I do not think it would be more than 5 or 6 feet. The depth depends entirely upon height of flood. It is dry again now—the water that was put in by the last flood has disappeared. Depth.
8875. What was the date of the last flood? From the 21st to the 24th of January, 1885. Flood.
8876. Does the river Darling actually flow into the lake at flood-time? Yes.
8877. Is there any drainage off? Yes, into the river; the fall from the lake is toward the river. Drainage.
8878. What is the character of the surrounding country—is it high land all round? The country surrounding Woytchugga Lake is of a sandy nature. I do not think the water could be drawn from the lake for storage elsewhere. Country.
8879. Is it much higher than the bed of the lake? Not much.
8880. Do you think it would be possible to retain the water in the lake? Yes, at or near its junction with the river. Storage.
8881. By what means? A dam and sluice.
8882. Across the drainage channel? Yes.
8883. What would be the height of the dam? I do not think it would require to be more than 15 feet high. Dam.
8884. And about what length? About 80 or 100 feet probably.
8885. And the water in that lake when dammed up as you suggest would command all the surrounding country? Yes; the country surrounding the lake and fronting the creek. I fancy it is a shallow lake. In estimating 15 feet as the height of the dam, I am allowing 5 or 6 feet above the surface of the ground.
8886. What is the character of the banks on which the ends of the dam would abut? Black soil. Banks.
8887. Is it good holding ground? Yes, I believe it is.
8888. What other lakes are there which are filled by the river in flood-time? There is the Wangalara, Poopelloe, Gunyulka, Pollioillaluke, in the county of Werunda; Terryawenya, Ratcatcher's, Reed's or Ballabouka, Sawyer's, Brummey's, Victoria, Waterloo, and Eucalyptus, in the county of Livingstone; Malta, Bijiji, Tandure, and Baleka, in the county of Tandora; Menindie, Emu, Cawndilla, Tandou, Nettlegoe, and Speculation, in the county of Menindie; and Woytchugga, on the southern boundary of the county of Menindie. Lakes filled from Darling.
8889. *Chairman.*] I suppose you have never tried to aggregate the areas of all those lakes? No, I have not even had time to see them yet.
8890. *Mr. Gipps.*] Are they all of the same nature as Lake Woytchugga? I believe they are all similar.
8891. There are no particularly large lakes? None very deep, but they are all of considerable area.
8892. There are none of any great elevation? No.
8893. Do they all dry off quickly? Most of them do. The drainage of the flood-waters from the lakes will keep the river navigable below Menindie for eight or ten days after the river has fallen at Wilcannia, and after a larger rise, from two to three weeks.
8894. Do you know anything of the Baroorangee Creek? I do not know it.
8895. There are three or four dams there—I thought perhaps you might know something about them? No, they must be station dams.
8896. Is the Darling below Wilcannia invariably lower than the plains on either side? The bed of the river is always lower. Darling River bed.
8897. And are the banks always higher than the plains, or are they about level with them? As a general rule I think the banks are a little higher than the plains, but the difference in level is not much. Banks.
8898. What is the character of the rains; are they tropical, coming in heavy storms as a general rule? The heaviest rain, as a rule, falls in thunder-storms. There are also light rains of from 5 to 40 points. Rains.
8899. But do you ever get regular tropical rains? No, I do not think so.
8900. Do you know of any irrigation works at all in that part of the country? I do not know of any works of that kind worth mentioning, except the dam previously referred to across the Tallywalka Creek. Irrigation.
8901. Do they irrigate from that? No; it is for the purpose of diverting water into Teryaweynya Lake for storage.
8902. But there is no irrigation? No; simply storage.
8903. Have you ever seen the bed of the river quite dry? No; the lowest I have seen it was in April, '84, when the depth was about 7 or 8 inches where the bed was of a uniform and sandy nature. Supply in Darling.
8904. With what breadth? About 20 or 30 feet.
8905. Was the water fresh then? Quite fresh. I have heard of the water becoming brackish, but have doubts if such was the case. Quality of water.
8906. And flowing? Yes.
8907. Have you seen any large springs in the bed of the river or on the banks? None.
8908. What is the character of the country relative to its adaptability for surface canals—is it retentive soil? The red soil is retentive; the loss due to absorption would probably be greater in the black soil, but I think it might also be considered retentive. There is a good deal of sandy country in the district, which of course would be unsuitable for canals. Retentiveness of soil.

8909.

Mr. W. J. Hanna. 9 July, 1885.

8909. What are the prevalent winds in summer-time? I could not say; there are no constant winds.
8910. Are they continuous? No; occasional gusts from the south and south-west.
8911. Do you think that windmills could be used with advantage? In some places—on the plains for instance.
8912. But not on the borders of the river? No, I do not think they would be reliable on the banks.

Flood in the Dry Lake.

8913. *Mr. M'Mordie.*] Can you give us any particulars of the flood in January last? In the Dry Lake, about 20 miles from Wilcannia there was a hotel the roof of which can only be seen now. There were two teams loaded with wool in the lake, and as the rain was falling so heavily and water beginning to rise, the teamsters yoked up their bullocks to remove the waggons to a place which they considered was above flood-line, but next day the teams and loading were completely covered, although on each team there were three tiers of wool.

Rains.

8914. What quantity of rain fell, and in what length of time? The rain fell from the 21st to the 24th of January. At Wilcannia there were between 9 and 10 inches, but in some parts of the district the fall was 12 inches.
8915. And at what period was the hotel covered? About the 24th.
8916. *Mr. Gipps.*] What was the area of the watershed above? I could not say.

Area.

8917. *Chairman.*] What is the area of the Dry Lake? From 500 to 600 acres.
8918. And the hotel was built on an elevation in the centre of the lake I suppose? Yes; it was supposed to be above the flood-line.

Depth.

8919. Have any depths been taken? Yes; the depth soon after the flood was 36 or 38 feet in the deepest part.
8920. Is the water retained in the lake now? Yes, there is no outlet, and none of the flood-water is lost.
8921. Was the lake filled from the river? No, by the local rainfall.

Catchment area.

8922. Then the catchment area must be very extensive indeed? Yes, but it must be remembered that the fall of rain was unprecedented, and the greatest amount seems to have fallen in this direction. Southward the rain became lighter; at Menindie about 3 inches were registered, and 20 miles further south, from 30 to 50 points.
8923. *Mr. Gipps.*] Could we ascertain the area of the watershed in any way? I dare say it could be obtained approximately by inquiry, and by riding over the locality.
8924. It could not be obtained from any map? I do not think so.

Situation.

8925. *Chairman.*] How is it situated with respect to the Paroo? It is west of the Paroo a long way.
8926. In which county is it? The county of Young.
8927. What special benefit is this great mass of water to the people of the district? It is of use to the station and to the travelling public. The water is several feet above the banks of the tank which was excavated there.

Supply.

8928. How long do you think you may consider the water permanent? About four years.
8929. There is no drainage from it—no creeks running out of it? None.
8930. *Mr. Murray.*] Was it ever known to be full before? Nothing like so much as it is now.
8931. How do you account for the present excessive quantity? By the enormous amount of rain which fell in such a short time.
8932. *Chairman.*] Could you ascertain locally how long after the rain had ceased the water drained by its channels into this place? I think I could.

Further information.

8933. Could you also ascertain if that water came from the waste waters of the Paroo, and append the information to your evidence? I think so; a great deal of valuable information could be obtained in the district just now.
8934. We should be glad to receive any information you could obtain with reference to that particular flood? I shall be very glad to furnish any further information I may be able to gather, and much regret that my duties will not permit me to devote more time for that purpose.

THURSDAY, 16 *JULY*, 1885.

Present:—

Mr. DONKIN, J.P.,	Mr. MURRAY, M.P.,
Mr. GIPPS, C.E.,	Mr. M'MORDIE, M.I.C.E.,
Mr. LYNE, M.P.,	Mr. TARGETT, M.P.

W. J. LYNE, Esq., M.P., President, in the Chair.

Mr. F. P. Solling called in and examined:—

Mr. F. P. Solling. 16 July, 1885.

8935. *President.*] You are a licensed surveyor? Yes.
8936. In what district? The Gwydir. I have been there for six years.
8937. The tracing I have in my hand is by you? Yes. (*Appendix* EE.)

Supply of the Meei.

8938. And a report relative to the supply of the Great Ana-branch of the Gwydir and the Meei? Yes.
8939. What is the principal object you have in view? We desire to re-open the original river, the course of which has been altered during the past thirty years.

Principal river.

8940. Which is the principal river—the right or the left-hand branch? The left-hand branch.
8941. Does the largest quantity of water go down that river now? None at all, unless there is a rise of about 7 feet. It has been silted up on account of a large log coming across the mouth of the river. It is narrow at the junction, and it is completely silted up. The silt is 5 to 6 feet deep.

Silt.

8942. That is shown on the plan here? Yes. I have a plan showing levellings and sections prepared since I wrote that report. I produce it.
8943. Has the river become perfectly dry now? It is perfectly dry. During the past four years there has been water in it only once, I believe.
8944. Are there no waterholes? There are a few fair holes, but the water comes down so seldom that they are of no importance.

Bed of river.

8945. Of what size is the bed of the river? I suppose it is from a chain to a chain and a half in width.

Mr. F. P. Sölling. 16 July, 1885.

8946. Is the Gwydir or Great Ana-branch about the same width? It is from two to two and a half chains wide—in some cases more.
8947. Is there much settlement along the banks of the river? The land is nearly all purchased.
8948. Along the banks of the Meei also? Yes.
8949. Is it purchased on large holdings? Principally on large holdings, by lessees. The plan I produce shows to what extent the Crown Lands would be benefited. Alienated land.
8950. There appears to be nothing but reserves left? Nothing but reserves. There may be a few instances lower down in which, when auction sales were stopped, some unalienated portions remained. I calculate that there are altogether 135,320 acres of reserved land which would be benefited immediately.
8951. Is that on the banks of the river? Yes.
8952. Extending over what distance? I have gone back 3½ miles, and the distance down the river from junction to junction is 54 miles.
8953. Can you put in that plan in your evidence? Certainly. I can also give you the plan showing the district of Moree.
8954. What quantity of water now goes down the ana-branch? On an average, I suppose there would be a fresh five times every year. Supply in ana-branch.
8955. There is always plenty of water? Nearly always.
8956. Is it a sandy bed? No; a kind of yellow clay and shingle—gravelly. Bed.
8957. Is it deep? About 25 feet. The north channel has been formed principally during the last thirty years. They are building a bridge at Booloorоо, and the contractor told me that he had to go down only 4 feet below the ordinary level before he came on to the clay of the surrounding plain. There is no ancient river-bed. Some of the oldest residents say that it has been made by the action of flood-waters within the past thirty years. Depth.
8958. What do you propose to do? I thought that all the water now went down the north channel, and that as there was more than the residents required, it would be only reasonable to take away some of it at the junction and allow it to go down through the town of Moree along the original channel. Diversion.
8959. Does this obstruction prevent the water from going to the town of Moree? Yes, altogether.
8960. What water do they get there? They do the best they can. Last summer they had to sink in the gravel for water—about 4 or 5 feet down.
8961. Do you propose an overshot dam across the Great Ana-branch? That was the first proposal; but since taking the levels I am not riveted to either scheme. I think that if a low overshot dam were made (say) 4 feet it would be ample. About 10 or 12 chains of gravel would have to be cut through and removed—the two river beds would then be at same water level, and a rise of even 1 foot would be fairly divided—each branch would take its share according to width. Overshot dam.
8962. Has the Meei a sandy bed? No; it is similar to the ana-branch—gravelly in places, and scarcely any sand. Bed of Meei.
8963. You consider that if a dam of 4 feet were put across the Great Ana-branch it would throw a portion of the water down through the town of Moree to the junction? Yes, if a little gravel were taken away.
8964. Is the country level? It is all plain country.
8965. How is it that the people themselves have not done this if such a little work would supply the town? It is one of those cases in which any one's business is no one's business. Something of the kind was attempted, but the other side commenced to talk law and frightened them out of it.
8966. Is that the principal reason? I suppose so. Now the parties on the Gwydir side seem determined to do something, and as usual there is a little opposition. The stations which would benefit by the scheme are nine or ten in number. With the exception of a few large selections consisting of three or four 640-acre blocks and pre-leases, the land is nearly all in the hands of the lessees. Opposition the scheme.
8967. Is the soil of such a nature that a dam across the river at the point you suggest would stand? I think so; just below the junction there is an immense shingle-bank. The shingle is very large compared with the rest of the shingle; there are large water-worn stones, some of them weighing 10 or 12 pounds. Just after that there is a pretty rapid fall—the water runs strongly. Nature of bank
8968. And you think the dam should be there? Just below the junction.
8969. How far would a 4-foot dam throw the water up the river? A couple of miles fully. Back-water.
8970. Have the people along the Great Ana-branch used the water for other than stock purposes? I think not, excepting the case of the Booloorоо pumping works. With that exception the water is taken out by stock. Booloorоо pumping-works.
8971. There is no irrigation? Only in one instance, of which I have a few particulars. I took the levels, and to a certain extent supervised the watering. Macdonell and Company had 11 acres under cultivation. Last year was the first year; it took eight hours forty minutes' pumping, at a cost of £3 5s. The pumping per minute was 6,500 gallons. Irrigation.
8972. *Mr. Donkin.*] With what sort of pump? Centrifugal. Pump.
8973. *President.*] What did the eight hours' pumping do? In all 3,380,000 gallons were pumped, or on each acre 307,373 gallons. Effect
8974. Were the whole of the 11 acres irrigated in that time? Yes.
8975. To what depth? Such an immense quantity of water was delivered into the drain that we did not know what to do with it. When once the pump starts you cannot stop it. We estimated that about 13½ inches of water were put on to the surface. Depth.
8976. What became of the water? Most of it soaked in; the land was very dry—we had had no rain for five or six months.
8977. What sort of land was it? Red chocolate loam. Soil.
8978. Was the soil disturbed before the water was pumped on to it? It was ploughed; the crop was in at the time.
8979. What crop? Wheat. Crop.
8980. What was the result of the irrigation? No good result. The river came down rather late; the crop was too far advanced. Result
8981. *Mr. Donkin.*] What height was the crop? The crop had been eaten down twice, to prevent it from seeding.
8982. What did they do with it afterwards? They cut a little of it and made some hay, but it was a failure so far as the crop was concerned; the river did not come down soon enough.
8983. At what time of the year was this? It must have been early in November.

Mr. F. P. Sölling. 16 July, 1885.

8984. Have they tried irrigation for grass? No.

8985. *Mr. M'Mordie.*] How did you arrive at the quantity of water pumped in the eight hours forty minutes; was it gauged in the stream or estimated by discharge of the pump? I gauged the stream.

8986. *Mr. Donkin.*] What was the diameter of the pump? I believe it was nearly 2 feet.*

Effect on river.

8987. *President.*] Did the pumping affect the river? It must have affected it considerably.

8988. Did you observe any difference? No, not at this time, because there was a fair stream running down.

Distribution.

8989. *Mr. Donkin.*] How was the water distributed over the ground? There is a gradual slope from the bank of the river; the main channel was blocked at different points.

Main drain.

8990. What was the size of the main drain? About 6 feet wide. Part of it was raised, and other parts were let in according to the levels. On a great portion of the land there were 3 or 4 inches of running water. The ground was thoroughly saturated. I should think that half the amount of water would at any other time thoroughly irrigate the whole of the 11 acres.

8991. *Mr. M'Mordie.*] Is that all the irrigation which has been attempted with that pump? That is all. Macdonell & Company are adding 7 or 8 acres this year, and intend to irrigate it. They will have 18 acres under crop. The cost of pumping is about £9 for twenty-four hours, or £63 per week.

Cost.

8992. *President.*] That would be about 6s. per acre? Yes. Booloorоо Station paid the Company for eight hours forty minutes; they were pumping into the Midkin Creek, and they turned the water off that drain into the cultivation paddock. I may mention that the cost of the machinery was £3,500, and that the water was lifted 25 feet. The machinery is, I believe, the duplicate of the largest pumping machinery in the Colonies.

Machinery.

8993. Perhaps too much water was put on? Of course there was.

8994. Do you think your proposal is better than the proposal to dam the river lower down at Macdonell & Co.'s, about a mile down where there is a neck about 15 chains across? That is a matter which could be determined only by actual survey. I have thought of it since, but I have not examined the locality sufficiently.

Fall of country.

8995. Have you noticed whether the country falls away from the river? In every instance about there it does so. In a heavy flood the water runs in all directions from one watercourse to another.

Supply in ana-branch.

8996. Is there a constant stream running down the Great Ana-branch throughout the year, or does it fluctuate? On an average there is a running stream for seven months in the year.

Source.

8997. Have you been up near the head of the river? No; it is near Armidale.

Snow-water.

8998. You do not know whether there are facilities there for the storing of large quantities of water? No.

8999. Does the water come out of the snows? Several times I have known pure snow-water to come down as far as Moree. The only place, so far as my district is concerned, where dams could be put across to store water is about the junction of the Meei. Up to about 10 miles to the eastward there is almost a continuous sheet of water from 5 to 15 feet deep. If several dams were put across there an immense body of water could be stored. Some of the waterholes there are the largest in the district, and I believe are among the largest in the river.

Storage.

Height above sea.

9000. In your report you say there are wells in the Moree district 875 feet above the sea-level, but in the Railway Report Moree is said to be only 680 feet above the sea-level? I took the height by the aneroid.

9001. In no other way? No.

Selection.

9002. Is there much selection on the Great Ana-branch? It is the same as on the Meei; there are large selectors, but the land has been chiefly purchased by the lessees.

Petition.

9003. I suppose that all who have signed the petition which has been presented to the Commission are resident there? I do not know where they get fifty selectors. Several of the residents whose names are attached to the petition are not near the frontage.

9004. Would they be benefited at all? I suppose they would be indirectly. As far as I can see, it would make no difference if the water were turned, because in ordinary rises of 3 or 4 feet in the Great Ana-branch the water goes right through and runs to waste in the Barwon.

9005. You do not think that these people would be injured? Not in any way.

9006. And you think that others would be benefited if a portion of the water were taken down the Meei? I have no doubt of it.

9007. And the town of Moree would have a water supply? Yes.

Wells.

9008. Have you any knowledge of the wells in the district? I have an extensive knowledge of the wells. I sent in a lengthy report some time ago, giving full particulars.

Silt.

9009. *Mr. Gipps.*] Is there much silt in the Gwydir River in flood-time? A great quantity; it remains in what is called the watercourse, about 23 miles west of Moree.

9010. What is the character of it? It is a kind of clay.

9011. There is no sand in it? Little or no sand. It is very thick—more so in some freshes than in others.

9012. You recommend a low dam of 4 feet? Yes.

Diversion.

9013. At the same time you said that a log across the river had diverted it from its original course? Yes.

9014. Do not you think that a weir across would have the same effect, and would divert the river into some other course? I do not think so.

9015. Why not? Because the water would be able to run over the top of it.

9016. Would not the bed of the river silt up to the top of the weir? It is just possible that it would.

Depth of river-bed.

9017. What is the depth of the river bed below the surface? I suppose from 25 to 30 feet.

Surface-soil.

9018. What is the character of the surface soil? It is black soil to about 2 feet, and then it becomes a kind of friable yellow clay.

Fall.

9019. The top soil is good holding ground for water? No, it is rather the reverse.

9020. Is there any regular inclination of the country between the old and new beds of the river, or *vice versa*? I think, according to measurement, they are nearly the same; the Meei River has the greatest fall.

9021. That is the old river bed? Yes.

9022. What is the average quantity of water going down the river in an ordinary season? I have never made an estimate.

Freshes.

9023. What would be about the depth? The ordinary freshes are from 3 to 5 feet deep, and the water runs at the rate of from 3 to 4 miles an hour.

9024.

* NOTE (*on revision*):—I have since ascertained the diameter to be 20 inches.—F.P.S.

9024. What is the width? In the ana-branch from 2½ to 3 chains. It takes, as a rule, about five days to run down to about knee-deep at the crossings; then it continues to run, unless there is extraordinary dry weather, for months. Mr. F. P. Sölling. 16 July, 1885.

9025. At that depth? Yes; from 6 inches to knee-deep.

9026. What is the width? About 7 or 8 yards at some of the crossings.

9027. Is there a good current when it is low? It is a strong current. Current.

9028. You do not know the actual fall of the river-bed? No; the only idea I have is from the plan showing the levellings which I took from the junction.

9029. What is the character of the shingle? Very coarse gravel. Shingle.

9030. Is it mixed with clay? No, it is pure shingle.

9031. Do you know of any tanks in the district? I have sent in a complete list giving details of the tanks and wells. Tanks.

9032. Do they hold water well? As a rule they do.

9033. What is the nature of the soil? Generally black soil. The best tanks are away from the river. Soil.

9034. Are the winds pretty regular in the district? In the last year there has been scarcely any wind. When you had your first fall of rain down here it was boisterous for about a week; with that exception we have had scarcely any wind this year. Wind.

9035. You could not fly windmills then? There are some up there; some are a success, others are not. Windmills.

THURSDAY, 30 *JULY*, 1885.

At Hay.

Present:—

MR. DONKIN, J.P., | MR. LYNE, M.P.,
MR. GIPPS, C.E., | MR. TARGETT, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. George Philben called in and examined:—

9036. *President.*] You reside in Hay? I reside in Hay at the present time. Mr. G. Philben. 30 July, 1885.

9037. What is your employment here? I am doing nothing at present. I was Road Superintendent in this Colony for twenty-one years, ten of which I was in charge of Riverina district, making Deniliquin my head-quarters.

9038. Were you here a considerable time? Yes.

9039. How long? From 1870 to 1880—ten years.

9040. Over what extent of country did your duty take you? From Urana to Wilcannia, and from Wentworth along the Murray to Tocumwall.

9041. What is the nature of the country? Level, flat country.

9042. The ordinary Riverina plains I suppose? Yes. Riverina country.

9043. The land as a rule I suppose is rich? Yes, very rich.

9044. During the time that you were Road Superintendent did you experience any extraordinary dry seasons? Not so dry as at present; there were floods in my time from '70 to '75; since then the rainfall was less and the floods not so high. Seasons.

9045. Along the streams you are acquainted with I suppose the flood-waters are not conserved in any way, but simply allowed to run to waste? Except where Nature conserves them; there are several natural reservoirs or lakes on the Murray, the Murrumbidgee and the Darling. Flood-waters. Natural reservoirs.

9046. And on each of these rivers, the Murray, the Murrumbidgee, and the Darling, the flood-waters flow into these natural lakes? Yes, while the rivers are rising.

9047. Are there many of these basins? Yes, a great many on each side, at various distances, from 3 to 20 miles back.

9048. On what part of the river are they mostly situated? If you commence with the Darling, you have the Menindie Lake, and the Poomamaro Lake, Tarraweena Lake, and others. Lakes on the Darling.

9049. How far are they from the river? 2 to 3 miles I should say, the nearest; 15 to 20 the furthest. Distance from river.

9050. What height of flood does it take to fill these lakes? I suppose that when the water rises 14 or 15 feet it flows in in a strong stream. Filling from floods.

9051. Above what level? Summer level.

9052. That is 14 or 15 feet above summer level? Yes.

9053. There is a channel I suppose? Yes, a wide channel to each lake, probably 200 feet wide. Channel.

9054. What depth of water is let into the lakes when the river is in flood? I could not say.

9055. You can give an idea perhaps? I have never taken the depths; they are pretty considerable—20 or 30 feet in some places—they vary.

9056. How long after the flood will the water last? It lasts till the river falls to allow it to flow out again. Out-flow

9057. It flows out then? Yes, while the rivers are falling; some lakes run dry, others do not.

9058. Are no means adopted to stop it? There is nothing to stop it that I am aware of.

9059. The channel then is nearly as deep as the lake itself? Yes, in some instances.

9060. Could anything be done to impound the water? I think so—weirs and embankments. Weirs.

9061. Are there not suitable places at which dams could be thrown across the Darling? I am afraid not; I think you could not well throw a weir across the Darling. Dams on the Darling.

9062. Why? Owing to the nature of the soil; if you were to throw a weir across the Darling the probability is that the water would leave the channel and cut another for itself. I cannot see that it is possible to make weirs in the Lower Darling, Murray, or Murrumbidgee. Nature of soil

9063. Suppose you built a weir up to the top of the bank—a movable weir? The water would tear away the banks and make a new course for itself.

9064. Are there any rocky bars? Not as far as I know; you might throw a dam across the creek going into the lakes, but not in the main channel—I think that would be impracticable. Rocky bars.

9065. If there were rocky bars for foundations could you not do it? Yes, but you have no such bars that I am aware of.

9066.

Mr. G. Philben. 30 July, 1885.

9066. You know that there are plenty in the Darling? Not lower down I think; if you had rocky banks you might do it.

9067. If it were practicable to put weirs across the Darling, you could raise the water and keep a constant supply in the lakes? That is not the way I would do it. When the water is at its highest, if you had a weir across the channel to the lake from the river you might keep the water in it.

9068. But if you raised the water in the river 15 feet, you would obtain a supply of water to let into reservoirs? Yes, you could do so.

Depth of lakes.

9069. These lakes I suppose are about the same depth? I suppose so; I have not taken the depths; they must vary I should think, but that can easily be ascertained by soundings.

Irrigation.

9070. You know of no system of irrigation, even on a small scale, having been carried out on that part of the Darling? Nothing except for gardening. About Wentworth and at squatters' homesteads they pump up water for garden use.

Result.

9071. With what result? They grow splendid fruit—oranges and various other things.

Fruit-growing.

9072. I suppose they have not attempted to grow fruit without using water? No, they raise water for the purpose.

9073. Is it possible to grow fruit without using water? I do not think it is.

9074. The result is that where you have irrigation you get fruit, and where you have no irrigation you get nothing? Yes, that is so.

Flood at Wentworth.

9075. What other parts of these streams do you know? I went down to Wentworth after the flood of 1870 to construct embankments. The flood-waters rise very slowly there, about an inch a day, and they fall about the same rate. The flood of 1870 left the course of the river and crossed the country between the Murray and the Darling; it swept across the flats from the Murray at Wentworth into the Darling and cut immense channels across the streets and knocked down a number of houses.

Underground waters.

9076. How far were those channels from the main bed of the Murray? 3 or 4 miles away in some places; about 12 feet from the surface you find water underground in the town of Wentworth.

9077. Fresh water? Yes; the whole place seems to be afloat in high floods.

9078. Do you find it in all cases? Only in high floods.

9079. The inference from that then would be that the water percolates through? Yes.

9080. Does it come from the river? Yes.

9081. Does it rise and lower with the river for a considerable distance from the river? Yes; Wentworth is on a mud flat, and about 12 feet from the surface you find sand and water in flood-times.

9082. How far does that kind of country extend from the river? 4 or 5 miles, I should say.

9083. Then at all times, I suppose, according to the height of the river, there is an immense natural reservoir containing water? Yes; it forced up the flooring of houses in Wentworth; they had small dams around the houses and went in boats from one house to another; the water forced up the flooring inside, and if you put a stick down in the ground the water would come up. I think the next high flood will do great damage there.

9084. Do you know any other places along the course of the rivers where that occurs? I do. At Euston the flats used to contain water; they had embankments around the hotels and houses as at Wentworth.

Highest floods.

9085. The 1870 flood was the highest known there? It was the highest in the Murray; the flood of 1864 was the highest in the Darling; in 1870 the flood in the Murray was 29 feet 6 inches over summer level, and in 1864 the Darling flood was 32 feet above summer level; it is seldom that the two rivers are in flood at the same time.

9086. One is going down while the other is rising? Yes; one may be in high flood and the other low.

Width of flood at Euston.

9087. Does the water extend far out from the river at Euston in flood-time? Yes, on each side, about 3 or 4 miles.

9088. Did you find the same thing occur at Euston as at Wentworth, that is, the water percolating through the sand? No, but it would do so I am sure.

9089. Do you know anything of the country about Albury? No; but I have been to Corowa, and to the head of the Murrumbidgee, and all over the Manaro country.

Murray water reaching the Edward.

9090. Do you know anything of the fresh that evidently runs out from the Murray into the Billabong? I know that in high floods the water from the Murray finds its way into the Edward about Tocumwal, at Tuppal, and at Gulpa Creek, and some other places.

Lakes on the Murray.

9091. Can you give us any facts about the flood of 1870? The whole country was flooded on each side for a distance of 3 or 4 miles on an average. There is a large lake called the Moira and also another above Moama, both of which are filled from the Murray.

9092. Are they only filled by floods? That is all, I think.

9093. As a general rule I suppose these lakes or depressions could be much oftener filled if means were taken to raise the water in the river and cut channels? Yes; my idea would be to cut channels into them so as to allow the water to flow in freely and to take means to prevent it flowing out when you have it in. There are a number of lakes about Swan Hill on the Victorian side; in some cases dams have been put across these to prevent the water going into them.

9094. What for? For the sake of the grass which grows in the depressions.

Lakes on the Murrumbidgee.

9095. Is that done on the New South Wales side? I am not aware that it is. There is the Yanga Lake on the Murrumbidgee; there are a series of lakes near it; the water flows first into the Yanga Lake and then into the dry lakes; I have observed embankments across from Yanga Lake to the dry lakes on the road from Balranald to Moulamein.

9096. The water from the Murrumbidgee above Balranald passes through these lakes towards the Edward, 20 miles from the Murrumbidgee? Yes. Again, at the Paika Lake the water flows in from the Murrumbidgee; that lake is about 3 miles across; when it is full it works its way down to Euston, and does not come back to the Murrumbidgee again.

9097. So that below the junction of the Lachlan and the Murrumbidgee the country is very flat, and a series of depressions are formed into lakes at flood-times? Yes.

9098. These are in some cases 20 or 30 miles from the river? Yes.

Murrumbidgee and Darling waters joining.

9099. Have you known the waters of the Murrumbidgee and the Darling to join midway or to meet each other in the floods of '64 and '70? They came near to each other.

9100. What is the cause of their not meeting? High land—a sand ridge.

Mr. G. Philben. 30 July, 1885.

9101. Would it be possible to cut through that sand ridge to allow the waters to meet? Yes. I consider it would be advisable to connect all these rivers by cuttings, and plant trees on each side of such cuttings for 20 chains or so.

9102. What is the distance between the two points which the waters from the respective rivers reach? I could not say without taking measurements.

Well at Mount Monara.

9103. Do you know anything of wells in the district which you are in? No, except the well at Mount Monara on the road across to Wilcannia.

Depth.

9104. What depth is that? 100 to 200 feet in sandstone I think.

9105. Is the water found in sandstone? Yes.

Quality.

9106. Is it good water? Yes; but in reference to wells and tanks you would get better information from the Department of Roads, Sydney, where they have all particulars as to depth, &c.

Soakage.

9107. Have you ever noticed that in these rivers the water gets away at various points—soaks into the ground, and leaves the river by underground channels or by percolation? I believe that in some places it does.

Discharge of rivers.

9108. Has it come under your notice that the volume of the river is decreased in some points? Yes. As a rule all the rivers have a large volume up above near the high lands, while down below in the flat country they are narrow. Take the Lachlan for instance; you can scarcely notice where it goes into the Murrumbidgee—where the Murrumbidgee enters the Murray it is a very narrow channel. I believe that the waters of the Murrumbidgee find their way by other channels into the Murray. When the country about Wentworth to the junction of the Murrumbidgee is flooded there is a network of creeks and billabongs which are filled from the river.

Rise and fall of rivers.

9109. This country is so level that if water is kept at a slight elevation over the surface the whole country would be under command for irrigation, would it not? Yes, certainly. The water coming down to Wentworth from the heads of the rivers comes very slowly; the snow-waters generally come after the flood-waters have passed; after the floods the lakes commence to empty themselves out again, thereby causing the water to rise very slowly in the rivers lower down.

9110. The water leaving the lakes again after they have been filled causes the river to rise slowly? Yes, it never rises rapidly below here; it has to fill the lakes before it comes down; then the lakes begin to pay the water out slowly; it may rise about 1 inch in a day for three months at Wentworth, and fall again at the same rate.

Talyawalka Creek.

9111. Do you know anything about Talyawalka Creek? Yes; I made sections over it at Menindie and Wilcannia, for bridges on the road Wentworth to Wilcannia, and Wilcannia to Booligal. It leaves the Darling above Wilcannia, and flows back into the Darling below Menindie.

Ana-branch.

9112. Do you think that the water flows underneath the surface between those two points? I think it must. There is an ana-branch from the Darling below Menindie into the Murray. Where it leaves the Darling the squatters made a cutting 14½ feet above summer level, so as to allow the water from the Darling to run into this ana-branch.

Cutting.

9113. The bed of the cutting? Yes; the bed of the cutting from the Darling, to allow the water into the ana-branch, was the height stated over summer level—15 feet.

9114. How is it that at that point the outlet was so much higher than 15 feet? It is only a short distance below Menindie where this cutting was made.

9115. You said that the outlet into the lake at Menindie is 15 feet above summer level at the present time, and that the squatters lowered this outlet to 14 feet? That refers to the cutting into the ana-branch below Menindie.

9116. Then that must have been much higher than one of the lakes? It gets filled up with sand, and has no connection or reference to the lakes at Menindie; the level is of course lower as it is lower down the river.

Artesian water.

9117. Do you know of any instance in this part of the country where there is artesian water? No. I think it desirable to sink for artesian water between here and Deniliquin, and here and Booligal.

9118. Have you any theory that there is artesian water there? I have not; we do not know what is underneath.

9119. If the geologists say that there is no artesian water, do you think that it would be worth while going to the expense of sinking? I think that it is very difficult for geologists or any one else to form an opinion on that point; it has not been ascertained by borings, and there is no outcrop or strata to indicate what is under the surface.

9120. Our Government Geologist says that there can be no water in the whole of that country except from the local rains? How can he say so, in the absence of borings or outcrop of some strata?—the cost would not be so great after all to put down a few borings.

9121. Well, he says so: do you think that in the face of that it would be wise to go to the expense of sinking for artesian water? The squatters are sinking at great expense; if you were to sink two deep shafts they would afford some test of the ground and let the squatters know what they might expect.

Value of irrigated land.

9122. How would you estimate the difference between the value of land which could be well irrigated and land which is in its natural state? I have had no experience of irrigated land: the difference would be very great, I have no doubt.

Depth of bores.

9123. *Mr. Donkin.*] What is the depth of any sinking here? 200 or 300 feet.

9124. You do not know of any deep shafts—2,000 feet? No; I was told that a shaft was sunk by Mr. Taylor, of Euston Station, to about 400 feet, and that it went through shale.

Trial shafts.

9125. You think that it would be advisable for the Government to put down one or two deep trial shafts? I do, certainly.

9126. At present the mode of procedure is only haphazard; they have no idea where they ought to sink for water? No, they have nothing to go by.

Willandra Creek.

9127. You know Willandra Creek? Yes, I have crossed it several times.

9128. Do you think that there would be any great advantage in having a weir put across the Lachlan near the mouth of that creek? Yes; it would be an advantage to dam the rivers where they are not navigable, but it would be impracticable to dam them where they are navigable.

Out-run of Lachlan.

9129. You say that the Lachlan runs out into a flat or swamp which is hardly noticeable? Yes, near Oxley, where there are extensive reed-beds and swampy ground.

Mr. G. Philben. 30 July, 1885.

9130. Is there underground soakage there? Yes, I think so; water find its way underground into the Murrumbidgee, and also the Murray.

Dams on the Lachlan.

9131. You do not know of any dam which has stood in the Lachlan? No; I have no knowledge of the Lachlan above Booligal, but I believe it is quite practicable to construct dams on it, and that they would be of great advantage in conserving water.

9132. Do you think it could be done? Wherever you have suitable ground of course it could.

Objections to dams on the Darling.

9133. You say that you do not think it possible to put a weir across the Darling? Not in the Lower Darling.

9134. If you could do it in the Upper Darling, why not in the Lower Darling? Because in the one case the ground is suitable and in the other it is not; the country in the Upper Darling is of a different formation from that in the Lower Darling, being rock and hard granite, with suitable foundation for weirs.

Movable weirs.

9135. *Mr. Gipps.*] What is your objection to the construction of movable weirs across the Darling? I think it would be impracticable to construct them in the Lower Darling.

9136. On what account? The nature of the country: if you put an obstruction in the way of the channel the water goes underneath or cuts a fresh course.

9137. Are you aware that with movable weirs you can let the water down flush with the bed of the river in times of flood? Yes, but it is very difficult to interfere with the waters of the Darling, from Wilcannia downwards.

9138. If the dam had movable wings what objection would there be to it then? No objection, but I think that the expense would be so great that the work would be almost impracticable.

9139. Are you aware that they are constructed in France and other countries at £20 a foot? We have not the same kind of country in this part of Riverina; I think the formation is different.

Bed of Darling.

9140. What is the bed of the Lower Darling—are there any quicksands? Yes, 12 feet below the surface at Wentworth there are quicksands.

Windmills.

9141. Do you consider that windmills are a fairly reliable power to raise water at all seasons? I do not think they are—they do not seem to work well.

Winds.

9142. Are the winds sufficiently continuous? No, I think not.

9143. Do you think that they could be worked to advantage as air accumulators? I do not know; they had a very good windmill of the latest construction at Perricoota, and they had to take it away as being unsuitable.

9144. Do you know the diameter of the wheel? No; it was one of the most modern, but they had to do away with it and substitute steam power.

Irrigation.

9145. *Mr. Targett.*] Do you know of any irrigated country around a dam? No.

9146. Some of the gardens in the town are irrigated? Yes, the Chinese gardens.

9147. Do they flood the land with water? They water their gardens from the river and wells here and at other places in Riverina.

Results.

9148. Are good results obtained? Yes, very good indeed.

9149. Through any seasons? Yes.

9150. The soil is very productive when irrigated? Yes, very productive.

9151. Would it be possible for irrigation to be carried on at a profit if the water were raised by steam power? I have had no experience to warrant me in offering an opinion, but I think it would. I have seen irrigation at Nevada; they bring the water down from the mountains by cut channels and flumes, and let it run in; it was very poor-looking country, full of boulders and sand and sage-bush, but by allowing the water to run over it they have succeeded in growing all kinds of produce in the greatest abundance.

9152. Do you know in what places they obtain water in this district by sinking? We have tanks and wells all the way from here to Booligal and Wilcannia; besides they have tanks and wells on all the stations.

9153. Do you know that there is water obtainable in wells not above 12 feet deep? No.

9154. Do you know Mr. Gibson's place? No.

Mr. Allen Lakeman called in and examined:—

Mr. A. Lakeman. 30 July, 1885.

9155. *President.*] You were lately Mayor of Hay? Yes.

9156. You have resided here for some time? About fifteen years.

9157. I think you have a brewery? Yes.

9158. And some land selections? Yes.

9159. Do you carry out any system of irrigation on those land selections? No; we are 20 miles away from the river.

Irrigation.

9160. Have you any place near the river where you carry on irrigation? We have done a little there, but only in a garden.

9161. With what result? We can grow anything with water.

9162. And you pump up from the river? Yes.

9163. Is there plenty? Yes, for every purpose.

9164. If others did what you do, but on a larger scale, do you think the river would stand any amount of pumping? I think it would.

Supply in river.

9165. There is no fear of its going dry? No; if you were to stop it for twenty-four hours you would have the water over the banks.

Seasons.

9166. The seasons have been very dry about here lately? Yes, during the last four years.

Loss of stock.

9167. What have been the losses in stock? I do not know.

9168. You have had cattle of course? Yes. I think that the losses have been very heavy.

9169. What would the percentage be about Hay? I should think that half the stock had been lost.

9170. Do you think it possible, if the water were well conserved, to grow feed to feed the sheep in dry times? I should think so.

Storage of fodder.

9171. And do you think it would be possible to grow and store fodder to prevent the large mortality that takes place at present? Yes.

Want of water and feed.

9172. I suppose that one of the greatest drawbacks selectors have to fight against here is the want of water Not altogether. Last year the selectors who had made provision for water were badly off for want of feed where water was plentiful there was no grass; it was want of grass that killed the sheep.

Mr. A. Lukeman.

30 July, 1885.

9173. If a selector had water at hand to irrigate, could he not keep stock alive and carry on operations during any season? Yes; the drier the season the better the herbage will grow with irrigation.

9174. It is almost like a hotbed? Yes; if you have a January rain you can almost see the grass grow.

Caking of soil.

9175. Do you think that if water is run upon the land without the surface being disturbed it will cake the soil and thus do very little good? I think it will.

9176. But that will not occur if you disturb the surface? It does to a certain extent; some soil will cake under any circumstances; other soil will not. The black, heavy soil will cake, but not the red, loamy soil.

9177. Do you know anything about the Murray? No, I do not.

Distribution from Murrumbidgee.

9178. You can form no comparison between the system of the Murray and that of the Murrumbidgee? No.

9179. I suppose it will be acknowledged that, if a scheme be proposed by the Commission by which the Murrumbidgee can be diverted for the irrigation of the country, it will do a great deal of good? I do not know, unless you had some means of distributing it. Supposing that the supply of water were as large again as it is now, unless it were distributed on the top it would be of no use to us.

Supply for irrigation.

9180. Supposing it possible to throw either movable or fixed weirs across the stream and raise the water to the top of the banks so as to provide a supply when you required it, would not that give a large supply for irrigation as well as for stock purposes when the Snowy River water comes down? I think there is water enough now with conserving it, without the Snowy River.

9181. Do I understand you to say that there is water enough to supply the people residing in the district now? Yes, sufficient for the people who might reside here, if plenty of water were supplied to work their selections. As I have seen the river in the winter-time there is sufficient water, if it can be conserved, to irrigate the land of the whole district between here and the Lachlan. In 1870 the two rivers were really joined at different places between here and Narrandera—it ran over the banks.

The Merool.

9182. There is a watercourse called the Merool, which is a continuation of the river out from Narrandera: is there any theory that the water comes from the Murrumbidgee? It did in 1870.

9183. How far did it go? Right across to the Lachlan; the plain was one sheet of water in 1870.

Conservation at heads.

9184. Then your idea would be that the water should be conserved first, I suppose, towards the head of the river, and then be diverted by means of canals on the higher country through the plains? That is what I think the most feasible scheme.

9185. You have had considerable experience of local government here? Yes.

Legislation.

9186. What legislation would you suggest to provide for dealing with the conservation and distribution of water? That is a matter I have not thought of; I look upon it as more of a national undertaking than a local one.

Local authorities.

9187. I am speaking of the distribution of water: suppose that an Act were passed giving certain parties power to deal with the matter, do you think it should be placed in the hands of local individuals? I am in favour of local government as a rule, but I think that the distribution of water would be something beyond the sphere of local government. I have never formulated any scheme upon the subject in my own mind. I have read about what has been done in America, and it seems to me a very good plan to have some supreme authority over the whole lot. Then you can have local authorities; my idea is that the local people can control their own affairs better than the Government.

9188. What do you think would be the value to a person with a small area of country if he had a constant supply of water? It is hardly possible to form an estimate.

Water-rate.

9189. What would they pay as a rate for the water? If a man were farming, and it could be made a certainty—and a crop would be a certainty in our climate with water—he could afford to pay double what he is paying now.

9190. Do you think 10s. or £1 an acre would be about the amount? If I were a farmer I would pay 10s. an acre.

9191. Do you not think it would be worth £1? I think it would be worth £5 an acre.

Weir.

9192. *Mr. Donkin.*] You were speaking of the Murrumbidgee: if a weir were erected in that river you think there would be a plentiful supply? I do.

Supply.

9193. Has the Murrumbidgee ever run out—has it ever been short of water? Never.

Expense of pumping.

9194. If they have plenty of water in it now, why do they not use it for irrigation? Because it is too expensive to pump it.

9195. If they could afford to pay 10s. or £1 an acre, the water would still have to be taken to the land? Yes.

Farms.

9196. Do you think it has had a fair trial? I do not think it has; but from what we can make out it is too expensive, and therefore impracticable. There are no small farms on the river; the land has all been bought by the capitalists.

Flooding black soil.

9197. Have you had any experience of flooding on the black soil? Yes.

9198. To any large extent? About 60 acres.

9199. Would it not be better to flood the land as it is now without breaking it, in order to grow the natural grasses? I hardly think it would.

9200. Is your experience against that? We do not try that course; we plough it up well.

9201. If you flooded here in summer would the land crack? I do not think it would crack much if flooded once or twice.

9202. You think that the water in the river could be conserved so as to prevent waste? Yes.

Navigation.

9203. But that would prevent navigation? Yes.

Irrigation.

9204. Which would be of most advantage to the country? Irrigation.

9205. *Mr. Gipps.*] What is the best power you use for pumping? Steam power.

Windmills.

9206. Have you tried windmills? They have been tried.

9207. What height have you to pump? We can pump 26 feet.

9208. Does the river percolate into the adjoining country on both sides? No, it does not; we do our pumping right on the river bank.

Wells.

9209. Do you know the average depth they have to go in sinking wells in the country? I sank a well 20 miles from the river, and there are three wells within 10 miles of us. We went 107 feet before we got the water. The water then rose within 60 feet of the surface. Sometimes it is struck at 80 feet.

Rise.

9210. Does the height of the river seem to affect the wells? Not a bit. I have a well over the river here, within, I suppose, 50 yards of the river, and the water does not come from the river—it is different water altogether.

Mr. A. Lakeman. 30 July, 1885.

altogether. The depth of the well is 86 feet. I put a well in the bend, just down the street here, in front of the Council Chambers, about 100 yards from Simpson-street, and the water in that well is quite salt. Mr. Esplin, of Tattersall's Hotel, put down several wells on his premises and got salt water.

Strata. 9211. Are there any shells? No, nothing but clay and sand; that is all that is found anywhere in this district; there is no stone of any sort.

Flood, 1870. 9212. *Mr. Targett.*] You said that in the flood of 1870 the rivers met: at what point was that? They ran out at different points. The Murrumbidgee overflowed just above the Show-ground, and the water ran across there and went into the Lachlan, across the Booligal Road about 5 miles from here. Wherever there was low ground the water was all over.

9213. *Mr. Gipps.*] The country must be very flat? There is not a hill anywhere in the district.

Windmills. 9214. *Mr. Targett.*] Do you know whether windmills have been successfully tried? I do not know.

9215. Do you think they will be of service; are the winds sufficiently strong and continuous? I think not; just when you want the water it is not available.

Steam. 9216. You consider steam too expensive? Yes, on a large scale; fuel is too dear.

Source of wells. 9217. You do not think that the water comes from the river into those wells? I think it does not; the water is of a different character.

9218. Might not that arise from the nature of the local deposits? No, it is not so. There is a large quantity of magnesia in the water.

Quality. 9219. Would you not be inclined to think that the water does come from the river? I should think it would come quicker, and that we should not have to go so deep for it if it came from the river. We sank below the bed of the river—it must have been 50 feet below. Dozens of wells were put down here in the old days, and in all they got salt water.

Salt water.

Percolation. 9220. You do not think much water is wasted here in percolation? I do not think that any is.

Impermeable stratum. 9221. *President.*] Then there must be an impermeable stratum close to the river bed? I think so; it is clay. If you go over the river you will find a Chinese garden, the proprietor of which put down a well. He used to get water from the river, and when the river went down the banks sloped in and he had to put a drive in to get the water.

9222. According to that evidence it is only at certain points that the impermeable stratum exists: many witnesses have stated that at various points along the river's course the water gets away? I should not think it did in this part of the river.

9223. If it does, it must be in certain particular spots? I should say that it does not get away between Narrandera and here.

Rise in wells. 9224. You said you had put down some wells in which the water rose to a certain height? Yes, about 60 feet from the surface.

9225. What is the cause? There must be a big supply underneath.

9226. Where does it come from? I do not know.

9227. That is artesian water? Yes, no doubt it is. It comes up to within 60 feet of the surface. When we broke through into the water it shot up 10 feet high, like a spout, but ultimately settled down. No doubt there is a very large supply of water under the ground here, wherever it comes from.

Underground supply.

9228. *Mr. Gipps.*] Did the drawing of the rods alter the level? Not at all.

Deepest well. 9229. *Mr. Donkin.*] What is the deepest well that you know of? I should think about 120 or 130 feet.

Test boring. 9230. Do you think it would be a good thing for the Government to put down a bore to test the depth of the water? Yes; we were promised that a borer would be sent here some time ago. Mr. Henderson promised to come and put a bore down on a spot chosen by himself, about 9 miles from here, on Hillston Road.

Natural grasses. 9231. *President.*] In irrigating do you think that natural grasses are more suitable than artificial grasses? I think they are better.

Lucerne. 9232. Do not you think lucerne and English grasses would be suitable? I think the natural grasses are better, and if they were better cultivated we should have better feed.

9233. *Mr. Donkin.*] You could not raise the artificial grasses by distributing the water over the surface as it is at present? No, I do not think you could.

Mr. John Keighran called in and examined:—

Mr. J. Keighran. 30 July, 1885.

9234. *President.*] What is your business now? I am Stock Inspector.

9235. Have you been long in this part of the country? Off and on about thirty-five years.

9236. On the Darling? No, principally on the Lachlan and here.

The Willandra. 9237. You are well acquainted with the Willandra Billabong? Yes, I was stationed on the Lachlan eight years.

Diversion. 9238. Do you think it possible to divert a permanent supply of water into that Billabong by damming the Lachlan? Of course if you were to put a dam on the Lachlan you would have a permanent supply, but you would be depriving the people down below, unless you could preserve enough during a big flood. At Hillston there would be no water at all. I have seen water so scarce in 1866 that you could not get a drink of water out of it.

Ponds. 9239. Has it been so since it was stocked with sheep? Yes, you can go miles and find nothing but a chain of ponds.

Movable weir. 9240. No harm would arise from placing a movable weir in the river, which could be lowered in flood-times? I have no experience of movable weirs.

9241. Have you had any experience of irrigation? None.

Value of irrigated land. 9242. Can you give any idea of the difference in value of irrigated and non-irrigated country? If you could irrigate it you could have paddocks in which to grow lucerne.

Food. 9243. Do you think it practicable with irrigation to grow enough food for stock in bad seasons? I do.

9244. You have no idea as to the quantity of artificial food which it takes to keep stock? No; we have always had to depend on the natural grasses.

Report on Willandra. 9245. What was the nature of the report you made to the Government about the Willandra Billabong? They wanted to dam it, and I said that the people below would never sanction it, as it would leave them without water.

Mr. J. Keighran. 30 July, 1885.

9246. When did you make the report? About eighteen months ago.
9247. You did not then consider the possibility of having anything but permanent dams? No.
9248. Do you think it possible to construct a dam that will stand? Yes, a dam to let the water run over it, or a permanent dam to let the water run down the creek.
Dam on Lachlan.
9249. Do you think it possible to dam the Lachlan? You could dam the Lachlan.
9250. Would it break out? It would break out and run all over the country. At One-tree you could start and cross thirty odd creeks before you got to the Lachlan where it used to break out.
Flood, 1870.
9251. Do you know whether the flood of 1870 went across through the Merool Creek and the Lachlan to the Murrumbidgee? Yes, it did.
Merool Creek.
9252. Then it would take very little to divert the waters of the Murrumbidgee into the creek? It would take a good-size dam. It breaks out at the back of Groongal.
9253. You think the water in the Merool Creek comes from where? It breaks through above Benerembah.
9254. And it runs down into the Lachlan? Yes.
9255. The Merool Creek is not a permanent creek? No, you would never notice that it was a creek at all till you saw the water in it; it is only a little dip.
Soakage.
9256. Is the soil sufficiently retentive to keep the water without soakage? There would be a lot of soakage.
9257. If the bed of the creek is dammed it would be possible to keep the water? Yes.
Command of plains.
9258. If you had water, the elevation is such that it would command all the plains by gravitation? Yes.
9259. Is the Willandra sufficiently high to command any great extent of country if water was diverted into it? It would go down upon Mossgiel.
Distribution from Willandra.
9260. If you diverted it into the Willandra, is that sufficiently high to send it to the right or left over the plains? You could send it all. A lot of shallow creeks break off, and it passes back into the Lachlan.
9261. If that Willandra were dammed you could command a great deal of country? You could send the water all over the plains.
Height of Willandra.
9262. *Mr. Donkin.*] What is the height of the Willandra Creek above the bed of the Lachlan? A flood of 14 or 15 feet in the Lachlan will run into the Willandra.
Weir.
9263. Would there be any objection to put up a weir in the Lachlan that would allow the flood-water to pass? No, but they would require the dams already there to preserve water. If they were cut away there would be no water at all.
9264. Are there no dams above Willandra Creek? No.
9265 There would be no objection to put in a dam? No, as long as they allowed the water to flow on.
9266. There would be no objection to an overshot dam 13 or 14 feet high? I do not think there would be any objection.
Length of Willandra.
9267. The Willandra runs down a couple of hundred miles? Yes, it goes a long way.
The Merool.
9268. You were speaking of Merool Creek? You can hardly tell that it is a creek at all. You can dam the Murrumbidgee to fill the Merool Creek.
9269. Where does it join the Murrumbidgee? Somewhere about Mr. Macfarland's station.
9270. Actually the Merool Creek does not find its way to the Murrumbidgee—it runs into the plains? Yes, and through to the Lachlan.
9271. In fact it intersects the whole country between here and the Lachlan? Yes, in little branches.
9272. Do you know of any instances in which they have used water got by pumping for irrigation purposes? No.
Weirs in Lachlan.
9273. *President.*] You said that if the Lachlan were dammed to divert the water into the Willandra the Lachlan would be dry, but suppose it were dammed with a regulating weir at various points so as to keep the bed of the river full of water? That is what it would require.
9274. There would be no objection then? No, as long as the people below were supplied with water.
Course of Willandra.
9275. You also said that if the waters were turned into the Willandra it could be sent through to the Teryaweynya Lake: is there no high or ridgy country between the Lachlan and the Darling, which would prevent that? No, it is a level country till you get to Ivanhoe.*
9276. Were you in that part of the country in the flood of 1870? I was.
9277. Do you know how far the Darling water went out? I do not; I know that the Lachlan water went over a large tract of country; I should say that the Lachlan water went back 70 or 80 miles.
9278. If the water could be turned into the Teryaweynya Lake, how is it that year it did not goin to it? I think it did.
9279. And you think that the waters actually joined? I think so.
Dams in Lachlan.
9280. *Mr. Gipps.*] What is the character of the dams in the Lachlan? Clay. Those are the only dams that would stand.
By-wash.
9281. How do they manage with the floods? Let it go over the plains by a natural by-wash, if possible.
Banks.
9282. What is the character of the banks of the river? Black soil.
Height of flood.
9283. What was the height of the Murrumbidgee in 1870, when the stream ran into the Merool Creek? I could not exactly say. It was running across the street in Hay, and it was up to the saddle-flaps nearly, 8 miles out here.
Cabbage Garden Creek.
9284. Is that the only instance you have known of the water flowing into the Merool Creek? There is another creek, called the Cabbage Garden Creek, 10 miles below Hillston.
9285. Could that be diverted into the Merool? It could.
9286. *Mr. Targett.*] We have always been given to understand that the Darling and the Lachlan have never joined, but you think they have? I am not positive, but I think so.
Reservoirs.
Banks.
9287. With regard to Willandra Creek, do you know of any place above where you could get reservoirs of sufficient size to keep it filled? No, there is no place there; the banks get higher as you go up the river.
Supply from floods.
9288. Could you not do it by damming? Yes, you could do it that way.
9289. Do think the floods sufficient to keep them filled? We used to get a flood that would go down the Willandra and the Merrowie Creek every three years. It would require an overshot dam, and the river would have to be locked. Wherever the water gets over the dam it cuts a way back again, and when the water returns it will cut a channel deeper than the bed of the river.

9290.

* Note (*on revision*):—Since answering this question I am doubtful if the Lachlan in any state of flood joins the Darling water or flows into Teryaweynya Lake. The Willandra appears to be absorbed by lakes and swamps running through Whitmibah, Kilfera N., N. Clare A and B, Kilfera A, B, and D, Manfred W., Mulurulu, Panbar, to large swamp called Juanbung. My experience in 1870 was not further N. than Kilfera and Manfred.—J. K.

Mr. J. Keighran. 30 July, 1885.

9290. Do you think the banks sufficiently impermeable above? The land is better above than below.

9291. *President.*] Is it your experience that near the bank of the river the land is higher than it is when you get a little further away on the plains? It is so, especially about the Willandra, but a little further down the land is more level.

9292. Do you not find that there is a little rise? Yes, but very little.

The Merrowie Creek.

9293. *Mr. Donkin.*] Is the Merrowie Creek any size? Yes, nearly as big as the Willandra.

9294. Then whatever was done to the Willandra Creek might be done to the Merrowie Creek? Yes.

Mr. Robert Gibson called in and examined :—

Mr. R. Gibson. 30 July, 1885.

9295. *President.*] You are a selector? Yes.

9296. In which part of the country have you selected? Half-way between here and Hillston, near the Merool Creek.

9297. You were not there in 1870, I suppose? No.

Merool Creek.

9298. There has been no flood in the creek since? No. I have seen the creek run once; that was from a heavy rainfall, when we had 8 inches in one night.

Want of grass.

9299. Has the country suffered much out there during the past two or three years for want of rain? From want of grass more than from want of water.

Tanks.

9300. Have you tanks? Yes.

Size.

9301. What size did you make them? 2,000-yard tanks are big enough for our paddocks.

9302. What depth are they? 8 or 9 feet.

Supply.

9303. When these are filled how long do you expect them to last? We expect rain to come about April, and they will last until the following April if they are filled in October.

9304. About six months? Yes.

Wells.

9305. Have you wells also? Yes; we get shallow water at a depth of 15 feet up to a supply for 1,000 sheep; that is about as much as a well will do.

Permanent water

9306. Have you deeper wells? There is permanent water from 70 to 90 feet.

Source.

9307. Is it local water, or does it come from some other source? I do not think it is local water.

9308. When you strike it does it rise in the well? Sometimes it does, and sometimes it does not.

Quality.

9309. Is that water good also? It is good stock water this side of our place; from there to Hay, 50 miles, you get water good for stock; on the other side there have been a number of poisonous wells.

9310. Does the water destroy the stock? Sheep will not drink it.

Poison.

9311. What is the poison? I do not know; the sheep will not drink the water.

9312. Can you get these wells anywhere? For 50 miles out. There are two wells at Cowl Cowl, within 30 miles of Hillston, which poisoned 5,000 sheep. At Old Gunbar a Government well was sunk about six months ago; it cost a lot of money, and the water is bad. The residents of the district have petitioned the Government to go further and try to get good water.

Whim and whip.

9313. By what means do you raise the water? By whim and whip.

9314. No windmills have been tried out there? No, not for stock.

Artificial feed.

9315. Do you think it possible to grow sufficient artificial feed and store it for stock, to tide over dry seasons, if you had the water at command, supposing a supply were diverted from Merool Creek? No doubt a certain area could be irrigated sufficient to carry us through a drought.

9316. Do you think a sufficient area could be irrigated to feed sheep through dry times? Yes.

9317. And do you think the selectors would do that if they had the water? We are trying to do it now without the water.

9318. But the results are very precarious? Yes; last year there was no crop at all.

Quality of land.

9319. If you had the water at command, could you not have crops every year? Yes; it is good cultivation land.

9320. I suppose it is level land—that there would be little expense in preparing the land for the water? No expense.

Water-rate.

9321. What do you think the selectors would be prepared to pay per acre for land irrigated? They would be prepared to pay a fair value if they could ensure good crops.

Value of land.

9322. What do you think would be the difference in the value between irrigated and unirrigated land? I think it would double the produce of the land.

Evaporation.

9323. In these tanks that you sink 9 feet deep do you find much evaporation? Yes; it requires very heavy rains to keep up the supply.

9324. Does the water go by stock drinking it, or by evaporation? It goes by drawing it if we work a shallow well.

9325. I am speaking of tanks? I think that as much goes by evaporation as in any other way. The evaporation is considerable.

Percolation.

9326. *Mr. Gipps.*] Is there much loss by percolation? Not after the first year.

Dams.

9327. *Mr. Donkin.*] Have you dams on the Merool Creek? There are dams.

Merool channel.

9328. Is it a well-defined channel? Yes.

9329. If you had dams, could you not conserve the water? On the stations I have seen the water dammed and conserved, but it is shallow; there is no depth, and it spreads over a lot of country.

9330. If you had dams on the Merool Creek, would it pay you to use the water for irrigation? If we had the water it would be worth trying.

9331. You would get the water the first flood that came? I have been there ten years, and have only seen the water dammed back by a station dam one summer.

9332. Could you say from experience what the value of water would be for irrigation? No.

9333. Have the farmers tried it? They have no water to try it with.

Shallow wells. Sweet water.

9334. *Mr. Gipps.*] In what direction do these shallow wells with sweet water extend? There is a strip of country about 16 miles long, and in places you can trace it by the cooba trees. In some places it goes into basins, and then into water channels again not above 10 or 20 yards wide. The tree is a native willow.

Cost of wells.

9335. What is the cost of sinking these wells? About 10s. a foot, all material being provided by the owner.

9336. You have to line them? Yes, with timber.

9337.

Mr. R. Gibson. 30 July, 1885.

9337. What is the character of the soil? Clay and sand. Wherever you find the native willow it is a sure indication of water underneath. If there are a lot of willows there is a good supply; if there are only one or two the supply will not be worth much.

9338. *Mr. Targett.*] Did you lose much stock during the last dry season? Not this drought; we did eight years ago. Loss of stock.

9339. You have had plenty of water since the big flood? Yes. Water supply.

9340. Have you had sufficient feed? We had to cut scrub last summer, or we should have lost stock. Feed.

9341. What area do you allow for sheep for all seasons? The last three or four have been dry years; I should say from 3 to 4 acres per sheep. Acres per sheep.

9342. What size are your paddocks? 1,200 to 1,400 acres. Size of paddocks.

9343. You think it would not be safe to run more than a sheep to 3 or 4 acres? No.

9344. You have never had water come down the Merool Creek except in the case you refer to? Never, except on that night.

9345. How long did the creek flow? There was water enough for a long time; it was flowing for three or four months. The station dam was washed away by that flood. Flow in the Merool.

9346. In the ordinary seasons the land would not carry more one sheep to 4 acres then? Yes; in good seasons a sheep to 2 acres.

9347. *Mr. Donkin.*] Which is the best course to pursue—to eat the grass well down in good seasons, or to carry a moderate number of stock in all seasons? We have tried a moderate amount all through, and experience has shown we have been right. We have had no loss. If we had stocked heavily in the good seasons we should have had to clear all away last year. It was a very dry year; we had not more than 8 inches of rain, and we had not to work the wells. Stocking.

Mr. George Sides called in and examined:—

Mr. G. Sides. 30 July, 1885

9348. *President.*] In what part of the country do you live? I live 17 or 18 miles north-east of the last witness.

9349. What area of land have you? 2,500 acres.

9350. It is a family selection I suppose? Yes, it belongs to the family. Selection.

9351. Do you run stock on it or cultivate it? I have cultivated some, but I run stock on it generally.

9352. Do you find that you can ensure crops without irrigation? I find that I cannot. Crops.

9353. How many years have you been there? Four years.

9354. And you have had dry seasons all the time? Yes. Season.

9355. Have you had any losses in stock? Not many; I did not stock much. Losses.

9356. You have had no losses? No serious losses. I did not see my way to buy stock to lose them as my neighbours were losing them; I therefore sold my grass.

9357. How many acres of your land does it take to carry a sheep? In a moderate season, between 2 and 3 acres will carry a sheep. Acres per sheep.

9358. Have you any wells? Yes. Wells.

9359. What depth? 142 feet. Depth.

9360. Did you get the shallow wells the last witness was speaking of? No.

9361. Is it a good supply of water? No. I went through yellow rock, and got it in 55 feet. Supply.

9362. Do you know what gypsum is? Yes; it was not that; the rock I speak of is brown and very hard. It will not shoot; I put sixteen shots in and they had no effect. Strata.

9363. And you got through that? Yes.

9364. What distance? About 7 feet.

9365. How far below did you go before you struck water? I struck water just below that about 10 or 12 feet.

9366. What was it in? Sand.

9367. Did the water rise? No, that did not rise. I went through that water, which I believe would have poisoned anything, and I got good water in three veins of sand about 142 feet deep. Rise.

9368. What did you go through just above that water? Sand.

9369. Did the water rise? Yes, it came up over 70 feet in the shaft.

9370. Was there a good supply? Yes. Supply.

9371. Have you more than one well? No.

9372. Have you tanks also? Yes. Tanks.

9373. What depth do you make them? 9 feet 6 inches. Depth.

9374. Does that water last six months? It depends on the stock and the weather. If the weather is windy and hot, the water will not last. Supply.

9375. You have no idea of the amount of the evaporation in windy weather? I have a tank over 2 chains in length by 72 feet, and I noticed that in one windy week it went down about 7 inches. Evaporation.

9376. The wind I suppose causes greater evaporation than heat? Oh, there is no comparison.

9377. Do you think that a 9-feet tank will last for ordinary times? That will depend upon the number of stock coming to it; with an average supply it would last in ordinary times. Supply.

9378. I believe you have spoken to the last witness about some poisoned wells? Yes, there are some within 4 miles of where I have my wells. Poisoned wells.

9379. Have you known any sheep to be poisoned? I have been told of it by station hands. When I spoke of putting shafts down they advised me not to do so.

9380. You have not had stock poisoned? No. I have not used the well; just as I was ready for it a storm came and filled the tank.

9381. Have you used water from the well? No, but I could drink it myself.

9382. What did you do with the water that is supposed to be poisonous? It did not make 200 gallons a day; the drift was too small to be of much injury.

9383. You have not puddled it off? No, I slabbed it.

9384. Do you think that if other selectors out there were able to obtain water they would avail themselves of itand grow any quantity of fodder? I see no reason why they should not; it is the very thing we want. Water supply to selectors.

9385. Have you any idea as to what would be the increased value of the land if we could get irrigation? The increase would mainly depend on the supply of water. Value of land.

9386.

Mr. G. Sides. 30 July, 1885.

9386. I mean if there was sufficient for irrigation? My opinion is that it would double the produce of the land.

9387. Then its value would be doubled? No, I do not say that, because the expense in connection with irrigation would take off a great deal.

9388. If you put in a crop at present you have no certainty of getting a return? No, we have no certainty that it will come up.

9389. Then irrigation would double the value of the land? Not at first—it would take time to prove it.

9390. If you had a market for your produce, and it would pay to grow corn, do you think that then it would double the value of the land? In case of mills and other things being provided it would become more valuable.

Water-rate.

9391. *Mr. Donkin.*] If you could get 20 bushels per acre would you be willing to pay £1 an acre? No; when the wheat was produced it would be worth only about 3s. a bushel, so that I do not see where the profit would come in.

9392. *President.*] I suppose it would be worth about 10s. an acre? That would be about it.

Irrigation.

9393. *Mr. Donkin.*] You have seen irrigation on the south side of the Murrumbidgee? Yes.

9394. That was for grain stuffs? Yes.

9395. Did it answer perfectly? That was only with water taken from a well.

Grasses.

9396. Which would it be advisable to cultivate, natural or artificial grasses? I think it is a great mistake to attempt to cultivate artificial grasses; unless it is done extensively it is better to have natural grasses.

9397. You think the natural grasses are more remunerative? Yes, in the long run.

Mr. T. F. Patterson called in and examined:—

Mr. T. F. Patterson. 30 July, 1885.

9398. *President.*] You reside at Eulonga Station? Yes.

9399. Is that far from Hay? About 30 miles north.

9400. It is plain country I suppose? Yes, similar to the country about Hay, even flatter.

9401. Is the land good? Yes, clay land.

Loss of stock.

9402. Have you suffered much from the last two or three dry seasons? Yes, and the losses of stock have been very great.

Wells.

9403. Have you any wells? Yes, we have four salt wells and three tolerably good ones.

Salt wells.

9404. What depth are the salt wells? From 75 to 80 feet.

Depth.

9405. You do not use them? No.

9406. What depth are the others? From 110 to 130 feet.

Rise.

9407. When you struck the water did it rise in the shaft at all? Yes, from 38 to 50 feet.

Source.

9408. Do you conclude that the supply of water is local? It must come from somewhere; you can see it running.

9409. Which way? The same way as the river, from east to west. When you strike the water you can see it coming through the shaft in a small stream. I have stood at the bottom of a shaft for hours and seen the water running through it.

9410. Do you think it has any connection with the rivers? I do not think so.

Channels.

9411. In striking the water do you find that it has a defined course, or do you find it promiscuously over the plains? In courses or small channels—promiscuously on the plains.

Quality.

9412. It has not one single course? No; I have sunk a well in one spot and found salt water, and 9 yards away the water has been better, thereby showing it has several courses and qualities on the same level.

9413. Would not that show that the good water runs in one channel? I think there are various water-courses, some salt and some fresh.

Channels.

9414. Do you think that there is a general drift of water in the whole plain, or that it runs in channels? It runs in channels. You either strike the water or you miss it altogether. You might put down a number of trial shafts without striking water.

9415. The good water is lower down than the other? Yes, from 35 to 50 feet, but in a similar kind of stratum-drift.

Good water.

9416. In what stratum do you find the good water? In sand drift. We get into clay, then come to a sort of sandy rock consisting of cemented sand.

Strata.

9417. The last witness said that it was sand in which the water was found, but sand which the water could not get through? Yes, there are wells like that; sometimes the sandy rock is just above the drift containing water, but not always.

9418. Have you passed through hard rock? No.

9419. Has the mortality of stock been due to want of grass or want of water? To want of both; there has been no growth of grass in consequence of the want of rain.

Growing fodder.

9420. Do you think the water would be much used if the people could get it for irrigation purposes—for growing fodder for the stock? Yes, I think it would to a considerable extent.

9421. Do you think it would be possible to keep stock alive for any length of time by storing forage? I think it would be possible to materially assist their existence by a very small assistance of artificially grown fodder.

9422. You have had practical experience of it? No, I have had no experience of it myself. When the paddocks are poor they assist their carrying capability in parts of Victoria by spreading hay.

9423. Do they grow the fodder? Yes, and they distribute hay or straw as just described.

Steam plough.

9424. I think that on the station you speak of they use the steam plough? Yes, a six-furrow plough.

Crops.

9325. And they put under crop some thousands of acres each year? They have 800 acres under wheat this year, and 500 acres under hay. They purpose cropping for two years, and then laying down lucerne, and if the lucerne succeeds they anticipate a large result. In some good land the lucerne tried in this way has proved a failure, because the land being so good has thrown up so much natural grasses which have choked the lucerne. At East Liddon, Victoria, they are trying a poorer land now—plain country.

9426. With the fodder which is grown they are able to keep stock alive? It is not a question of keeping them alive; they are able to keep them in better condition.

9427. Is it considered that the system pays? Yes; the straw they use there as fodder. There are straw stacks all over the station.

9428. What sort of country is it there? It is like the Deniliquin country, but stronger soil I think. Mr. T. F. Patterson.
9429. Have you any idea of the cost per head at which the stock are kept. No.
9430. They do not irrigate on that station, do they? No, they do not.
9431. Do you think it would be possible by the use of extensive machinery to do on stations in this country what has been done at the place you speak of? I think it could be done. In order to secure anything like irrigation we must have plenty of water. The rivers want locking or damming every few miles—the Lachlan every 2½ or 3 miles; if this is done it will irrigate itself. 30 July, 1885. Irrigation.
9432. And the water if available would be used for irrigation purposes? Yes.
9433. And the people would be prepared to pay a fair sum as a rate? Yes, I think so. Water-rate.
9434. What do you think would be a fair sum? I could not give you any idea.
9435. Have you any tanks? Yes. Tanks.
9436. What is the depth? 6 to 8 feet.
9437. How long do they generally last? We have tanks that last twelve months for 5,000 sheep. Supply.
9438. Does much of the water go away by evaporation? I do not think so, but the wind in this flat country wastes floods of water. The country between the Murrumbidgee and Lachlan, from Hay to Booligal, is so level that the water on the plains will almost run whichever way the wind is blowing. We excavate the tanks in the form of a square, and the earth is put round them in a sort of embankment a chain and a half away. We pump that full. The wind, however, plays upon it considerably. Waste.
9439. Do you think it would be of much service for stock purposes if the water were distributed on an elevation so that at any time you could supply your tanks? I think that would be a very costly arrangement; I do not see how it is practicable; you could irrigate close to the river. I think that the principal object to be gained is to provide water for irrigation to a considerable extent. The water is the all-important question. This must first be stored before you can consider irrigation. Distribution.
9440. *Mr. Donkin.*] Do you think it would pay to irrigate the land to raise natural grasses? I do not think so. Natural grasses.
9441. It would have to be cultivated? I think so.
9442. Have you known any instances in New South Wales? They are doing it at Groongal and Cooba.
9443. Will lucerne or artificial grasses pay for irrigation? I can hardly say; I do not see why they should not; you can get a very good crop of lucerne. The climate here (Lachlan) is one drawback to any cropping. Lucerne.
9444. Do not you think it would pay in dry seasons to cultivate? You cannot cultivate in dry seasons, for want of the needful rainfall. I have a crop in this year for hay (wheat), and expect a like result to last year and years previous—not worth cutting; there is a limited supply of water, as the river is not dammed sufficiently. Crops.
9445. They have never been prevented from doing that? They have not; Mr. MacFarland has attempted it. I consider the scarcity of water has been the chief reason it has not been done.
9446. There has been no scarcity of water so far, but many have expended large sums of money—I heard of £10,000 being spent to provide feed: would it not have paid better to have tried irrigation? Yes, but no one anticipated these continued dry seasons, and they had not made provision.
9447. *Mr. Gipps.*] Has there been any failure of crops on the Loddon farm? No, they have had particularly good seasons the last two years. Loddon farm.
9448. What is the average rainfall there? From 15 to 22 inches. Rainfall.
8449. *President.*] Do you think it advisable to throw dams across the Lachlan at various points? Yes, it is indispensable; we are now obliged to do it at our own risk. Damming of Lachlan.
9450. And it does no harm to the persons below, because it does not intercept the flood-waters? No; I consider every man who builds a dam on the Lachlan a benefactor to his neighbour below, because he stores water that would otherwise go to waste, and when the river does run it requires less flood-water to run it through.
9451. And you find that they stand? Yes.
2452. What do you make them of? Earth.
2453. You said that you have to do that at your own risk? Yes.
9454. Then do you consider that legislation should take place to give power to do this, because persons below might come and destroy your dams? They have done so several times. Legislation is absolutely necessary on many streams like the Lachlan and Billabong and many others I could mention. My experience dates since 1859, and I could tell many a story *re* dam-cutting. Legislation.
9455. And if a succession of dams were made, you would always have a large storage of water in the bed of the river? Yes. Succession of dams.
9456. Do you think the Lachlan would be much interefered with by a portion of the flood-waters being diverted into the Willandra Billabong? It would depend on where it was done. If it were compulsory that every holder of land with a frontage to the Lachlan put a dam up every 3 miles, then nearly all the flood-waters could be diverted into the Willandra without injury to any one. Diversion into Willandra.
9457. Supposing the flood passes down and fills up the dams, that is all that you require? That is all that we require.
9458. If the water was not intercepted so as to prevent that, no harm would be done? None whatever.
9459. *Mr. Donkin.*] Do you think overshot dams would do? They might be tried, if placed close enough together, but I think they put them too far apart. I have never seen one that did succeed. I do not see any difficulty about overshot dams as long as you put them close enough together so that water falls upon water. I would suggest that a Board of proprietors be formed of those interested, squatter or selector, to regulate the height and fix the places for the dams. The Chairman of the Land Board, or Police Magistrate, or Inspector of Stock, or District Surveyor, might be Chairman of such Board, with every Land District to have its own Board, because different portions of the different rivers require different management. While 3-feet dams would suffice in some places, 6-feet dams in others would be useless; hence the difficulty of legislating on the subject. Overshot dams. Boards.
9460. If anything of the kind were done, do you not think it should be done in a systematic way, without regard to either squatters or selectors or any one else: not only are those persons to be considered, but the Government have to look after their estate; and if anything were to be done, would it not be better to have it done by elective Trusts? I dare say it would; I am afraid, however, that it would take a long time to get that; the other we could get at once. Give us a Water Board at once, and, when necessary, elective Trusts. Trusts.

Mr. T. F. Patterson. 30 July, 1885.

9461. Your proposition is that there should be some local body created for the purpose, to erect and look after these dams? Precisely. Different parts of the country require different dams. Further up the river they want them bigger; further down they want them smaller.

Silt.

9462. *Mr. Gipps.*] Is there much silt in the river in flood-time? No; the only silt observable is that from the dams being cut.

9463. The dams must be silting up the bed of the river, according to that? They are to a certain extent, but it is only from the fact of their being cut. The earthwork of the dam is carried down the stream, and it causes silting to go on down below. Consider how few dams are on the river to the hundreds of miles of river.

9464. *Mr. Targett.*] You do not find your dams shallowing the stream above them? No.

9465. Then there cannot be any silting? Only when the dams are cut.

9466. *Mr. Gipps.*] Are there any dams in existence now in the Lachlan? There are.

9467. And is there any appearance of silting in the upper part? No, none.

FRIDAY, 31 *JULY*, 1885.

Present:—

At Hay.

MR. DONKIN, J.P., | MR. LYNE, M.P.,
MR. GIPPS, C.E., | MR. TARGETT, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Warden Harry Graves called in and examined:—

Mr. W. H. Graves. 31 July, 1885.

9468. *President.*] You reside in Sydney? At present.

9469. Have you resided in Riverina at any time? Yes, for some years—from 1857 until about 1872, constantly.

9470. You were in Riverina during the heavy floods of 1870? I was.

Floods.

9471. Will you state what you know about the floods of 1864 and 1870? I came down the Lachlan in 1864; I rode from Queensland; I came by Forbes, and came right down the Lachlan; when I got to Forbes I was informed by several people that it was impossible to ride down the Lachlan country, as it was all flooded; however, I said I would try, and I started; I worked about 40 miles below Forbes, to a place called Mulguthrie, I there found the Lachlan breaking over its banks in a wide stream on the nearest bank, and I had to keep going out towards the Bogan, to head the watercourses; in fact all the plains were under water from the Lachlan 40 miles below Forbes; all the billabongs and creeks were full, and water was running over the plains for miles and miles in the direction of the Bogan; I rode down parallel to the Lachlan to Booligal, about 50 miles from here; I am not sure whether it was in '63 or '64; to the best of my recollection it was in '63. In many portions of that journey I was not within 10 miles of the Lachlan; you could see nothing but water; I think I am within the bounds when I say that every day I had to swim some billabongs or creeks which in ordinary times would be only dry watercourses; even when I got to Booligal, coming in the direction of Hay, the Lachlan was out quite 3 miles.

9472. That is on the north bank? On the south bank. I was in Riverina in the flood of 1870; at that time Cobb's coach going from here to Deniliquin could not get within 12 miles of the township of Deniliquin about 4 miles from the Edwards River.

9473. How did they get into Deniliquin? They went by boat from a place called Pretty-pine, about 3 or 4 miles from the river; it was 12 miles from Pretty-pine to the township, but they went parallel to the river. Deniliquin was all flooded that year except the "Royal Hotel," the Gaol, and the Court-house; boats were coming up the streets; that flood was from the Edwards, which comes out of the Murray, about 25 miles from Deniliquin, and somewhere about 25 miles from Echuca; it comes out about halfway between Moama and Tocumwal. In the flood of '70 the water went all over Deniliquin Plains for miles and miles, and on Sir Patrick Jenning's Warbreccan Run; in fact the banks of the river are higher than the plains, and once the water is over the banks, the country is so level that the water runs out for miles and miles.

9474. Does it go all over the plains, or follow the watercourses? It follows the watercourses, which are very shallow; then it goes all over the plains for miles and miles, perhaps 3 or 4 inches deep. In that year the coaches could not get into Deniliquin coming from the Melbourne side; they had to take the horses out and swim them; the same thing occurred to the coaches coming from the south side; they could not get anywhere near the town, except on a sandhill; you could not get within 3 or 4 miles of the river anywhere.

Utilization of flood-water.

9475. In times like that, when the floods are so high, if the banks were cut and shallow channels formed in various directions, could not the water be diverted as required, to fill up the dry lakes, billabongs, and reservoirs? Yes, if you have the supply you can take the water anywhere.

9476. Do you know anything about the Murrumbidgee? Yes. I was coming up from Deniliquin about 1863, and I suppose there were quite a large number of people in a camp on the south side of the river for nearly a week; they could not get across the river with horses; the whole place was under water for 3 miles.

9477. I suppose that what I have said with regard to the Murrumbidgee would also apply to the Murray, that is, as to the utilization of the water? There would be no trouble if the flood-waters were diverted.

9478. And the same with regard to the Lachlan? The same there.

9479. Do you know how far the water went out towards the Darling in 1870? Not of my personal knowledge; I heard a great deal about it; the coach contractor at Booligal said that in the first 10 miles he had nine creeks to swim in going north, and that the water was out for at least that distance.

9480. What I was coming to was whether you know that the waters of the Darling and the Lachlan meet? I have heard of it, but I have not seen it; I know that the two rivers have met; the Macquarie, the Castlereagh, and the Barwon have all met.

Merool Creek.

9481. Do you know anything about Merool Creek? Yes.

9482. Do you know whether the waters of the Murrumbidgee went into that creek in 1870? I am sure that they must have done so, although I did not see it.

Dams.

9483. Have you had any experience of dams in the beds of these rivers, the Lachlan and the Edwards especially? Yes, I have seen lots of dams in the beds of the rivers, and in the billabongs particularly.

9484. Was there any difficulty in getting the dams to stand in the beds of the rivers? Oh yes, there is great difficulty. Mr. W. H. Graves.
9485. Would it be practicable to put overshot dams in the Lachlan? I think so. 31 July, 1885.
9486. In your opinion, would it be a good plan to throw dams across at various points in the rivers to keep the channels constantly filled? I think it would be an admirable plan; I have no doubt of it whatever. I can remember the time when there was no water in the Billabong; most of the water has been made permanent through damming entirely. The less frequently floods come down the river, the more porous the land becomes. I can recollect the time when there was only water for about 6 or 7 miles in the holes in the Billabong; were it not for dams there would be very little water.
9487. Were it not for dams in the ana-branches of the river the country would be in the same state as it was twenty years ago? Yes, there would be no water there at all.
9488. I suppose from your experience the only thing required to increase the carrying capacity of the country is water? That is all.

Mr. John Dill called in and examined:— Mr. J. Dill.

9489. *President.*] Have you been long resident in this part of the country? I have resided in the Riverina District for the last twenty-five years. 31 July, 1885.
9490. In what part of the Riverina do you reside now? On the Murrumbidgee, about 2 miles down the river, at Toogimbie.
9491. Have you attempted to carry out any system of distributing water from the river for irrigation? No, but I am just starting at that work. Irrigation.
9492. By what means? By the use of a powerful engine and a centrifugal pump. Pump.
9493. What quantity of water will it throw? About 5,000 gallons a minute. Force.
9494. Do you propose to irrigate? Yes.
9495. What extent of country? It depends upon what quantity of water the soil will take. It is impossible to say; it is more an experiment than anything else.
9496. What kind of soil is it you are intending to irrigate? It is a remarkably porous soil at any time. At present it requires an enormous quantity of water—it requires to be flooded. Nature of soil.
9497. Is it a loamy soil? Yes.
9498. Not the ordinary chocolate plain? No.
9499. Do you intend to distribute the water on the surface or to allow it to flow in channels? I intend to allow it to flow over the surface. Distribution.
9500. Are you preparing the land? Yes, by draining.
9501. What do you anticipate will be the cost of the work? As it stands, the cost is about £1,000. Cost.
9502. Before you are able to commence pumping? I am pumping now, but I reckon that it will take considerably more than I have expended.
9503. You have had no results? No, none to speak of.
9504. Have you plenty of water? Plenty at present, but there will not be at the end of the summer. Supply of water.
9505. But the water you take out of the river will not affect the supply, will it? No, I do not think it will do that.
9506. Why do you think there will not be water enough at the end of the summer? The pump would not do the quantity of work; it would have further to lift the water when the river is nearly dry. When the river is full the pump can do double the quantity of work. Capacity of pump.
9507. What height do you draw the water? 35 feet.
9508. But the pump will not suck more than 28 feet? It is not a perpendicular lift—that is about 20 feet.
9509. You say that at the end of summer there will not be sufficient water in the Murrumbidgee, but you mean that there will not be sufficient to enable you to pump in your present position: if you were to alter the position of your pump there would always be sufficient water, would there not? I anticipate being able to work the pump all the year round, but I am only making a start now.
9510. Does the Murrumbidgee become very low in summer-time? During the last dry season it has become very low. State of Murrumbidgee.
9511. Do you think the bed of the river could be filled by damming it? I feel sure it could. I think that the erection of a system of flood-gates on the Murrumbidgee would be a boon to every one from Narrandera down to Wentworth.* Damming.
9512. It would stop navigation, would it not? Not necessarily so.
9513. It would unless you had locks? Of course you would want locks.
9514. But suppose that locks were not constructed, do you think the navigation so important that it should prevent the river from being dammed? I do not. I think the water is of more importance than the navigation; therefore the river ought to be dammed or locked. It requires a practical man to give an opinion on this matter—some one used to this sort of thing in America. I have simply given my opinion. Importance of navigation.
9515. If there was another stream equal to the present stream of the Murrumbidgee thrown down the river, would there be plenty of water at all times for carrying out a reasonable amount of irrigation? I think so. Supply.
9516. Do you intend by means of your irrigation to grow crops for fodder or to grow grain produce? We intend to grow produce simply for our own consumption—not to any large extent. Crops.
9517. If you had plenty of water, do you think it would be possible to grow fodder to any great extent to keep your stock alive in dry times? My own opinion is that it would not pay. I think fodder can be grown so very much cheaper under more favourable conditions that it would not pay us. Fodder.
9518. Do you think that fodder can be grown in mountainous country and delivered here cheaper than you can grow it here? Yes, I do. If I only anticipated growing crops I should not have gone to any expense at all; I should never dream of going in for irrigation merely for cropping.
9519. I suppose it is a question with you whether it would pay or not? That is a question.
9520. But it is possible to do it? Is is quite possible, and my own opinion is that it will pay us to irrigate. I do not think it would pay to buy an engine for the purpose of growing crops, but it will pay us to use irrigation for our purposes. 9521.

---

* Note (*on revision*):—My evidence was that I considered it could *not* be dammed, but that locks could be erected or should be. I still consider the water the paramount question.—J.D.

Mr. J. Dill. 31 July, 1885.

9521. What I mean is, to grow fodder to any large extent: suppose you put in 2,000 or 3,000 acres a year, do not you think you could then tide over the bad season—would it not pay you? No, I do not think it would.

9522. Have you had experience of feeding stock on hay and lucerne? No; but I am acquainted with what has been done by others, who have admitted to me that it does not pay.

Irrigation. 9523. Do you think it would pay to irrigate for grazing purposes? I do.

9524. What would be the difference between 10 acres of land irrigated and the same area unirrigated? The difference would be very great. It would be at least five sheep for one with a certainty in one case, and with no certainty at all for the five sheep. It would certainly be four to one—I believe it would be five to one.

9525. In the one case with a certainty, and in the other without? Yes.

9526. Witnesses have told us that if you put water on the country at certain times of the year you can get a most luxuriant growth of grass? Yes.

Diversion. 9527. Do you think it would injure the residents lower down the river to divert a portion of the flood-waters of the Murrumbidgee? I do not think it would injure them if a certain portion of the flood-waters were diverted; but I think it is a matter that requires very careful consideration. I think that diverting anything but the flood-waters from those lower down would be a very dangerous policy—the flood-waters are the greatest possible boon to us.

9528. But supposing the flood-waters were diverted and the river were dammed at various points to keep it full, do not you think that the compensation resulting from keeping the river full would be far more than the losing of the flood-waters? There is a great deal, no doubt, about that.

9529. And if such a stream as the Snowy River were thrown into the channel, do not you think it would be an equivalent? Yes, I do.

Banks. 9530. Do you think it is possible to dam the river, and that the banks are of such a nature that the dams would stand? I do not think a dam would stand.

9531. Not an overshot dam? No.

9532. Are there no bars of rock? Not down here—I don't know of one; there is no bar as far as Balranald.

Dams. 9533. I suppose it is a question of engineering skill as to whether a dam could or could not be put across the river? It is. I have had a great deal to do with dams, almost from my boyhood. I have seen a great many dams carried away even in small creeks, and although the structures were apparently strong. I think that the erection of a dam would be a very costly matter and a very risky undertaking.

Engine. 9534. *Mr. Donkin.*] You said you were working an engine? Yes.

Power. 9535. What size? 20-horse power.

Pump. 9536. What size is the pump? 15 inches.

9537. Have you calculated what will be the cost of irrigation per acre? No, I have not. That is a thing which it will be very difficult to arrive at.

9538. You said you felt certain that it would not pay as a speculation? No, I did not say that at all. I said I did not think it would pay to buy an engine and pump for the purpose of growing fodder alone, except to use it both for irrigation, for grasses, and all sorts of fodder.

Merool Creek. Billabong. 9539. You were speaking in reference to the Billabong and Merool Creek? I have had a pretty long experience of both. I was on the Billabong years ago; there was hardly a dam on it. The creek in summer-time would be useless without dams. Their main supply is obtained entirely by securing the water during flood-time.

Dams Overshot. 9540. What sort of dams will stand in the Billabong? They are clay.

9541. Do not you believe in the construction of overshot dams? Yes; in overshot dams there is no water wasted.

9542. Of course you are aware that two overshot dams on the Culgoa Creek were carried away? Yes.

9543. Your opinion is that they will be best constructed in such a way that they will stand and cannot be carried away? Yes, I believe they can be in ordinary creeks or small streams, but in such a river as the Murrumbidgee I think the expense of an overshot dam would be great and the risk of being carried away great.

Diversion into Merool. 9544. Do you think it is possible to divert the water from the Murrumbidgee into the Merool Creek? I hardly see how it is possible; I think the expense would be too great.

9545. We have had evidence that in flood-time it was carried down the Merool Creek? I think that is entirely a mistake. It would have to run up hill all the way to the head of the Merool. By taking the river water from about Gundagai across to the Merool the latter could be filled, but the expense would be enormous—below Narrandera it could not be done.

9546. You said you did not think it would pay to store forage to feed stock in time of drought? No.

9547. Have you tried the system of ensilage? No, I have not; I have heard of its being tried.

9548. Do not you think that low overshot dams, 6 or 8 feet high, on the Murrumbidgee would stand? No, I do not; I have grave doubts about it.

Banks. 9549. Are the banks not 20 or 30 feet above summer level? 20 feet at least.

9550. And do you think that overshot dams 6 or 8 feet above summer level would cause such an obstruction that they would be carried away? Yes; lower down and even here the banks of the Murrumbidgee are of such a crumbly nature that they would be easily washed away.

9551. If the overshot were made with an apron 2 or 3 feet lower than the sides the water would fall in the centre? Yes.

9552. At what rate does the river run? I hardly know; I think at the rate of 3 or 3½ miles an hour.

9553. You do not know that the system I suggest has ever been tried? No, I do not.

Natural grasses. 9554. *Mr. Targett.*] You propose to irrigate for natural grasses? Yes.

9555. Have you a very large area which could be reached by irrigation? On our frontage country we can remove the engine up and down the frontage.

9556. Do you propose to cultivate many natural grasses? Yes.

9557. Do not you think it would pay to grow fodder by means of this irrigating plant, such as lucerne, which could be cropped without gathering it in? It is a test with me; I am only trying what can be done, and I have not yet ascertained what is best.

9558. It stands to reason that the cost of harvesting is very large, and if you can feed your sheep straight from the ground your expenses would be very much less than if you stored fodder? Yes. Mr. J. Dill. 31 July, 1885.

9559. Do you know of any case in which an effort has been made to dam the Murrumbidgee? I do not know that such a thing has ever been thought of.

9560. You have spoken about the friability of the banks below Hay? Yes; higher up it is not so bad. Banks.

9561. *Mr. Gipps.*] What kind of pump do you use? A centrifugal. Pump.

9562. What is the average discharge in eight hours? So far it has not been worked above 4,500 gallons. Discharge.

9563. From what lift? About 18 feet. Lift.

9564. And what is the cost of running it eight hours, including engineer's expenses, fuel, and everything? It is simply a test. I reckon it will cost £500 a year; I may be a little out in my estimate. Cost.

9565. Still you are working on figures now? Yes.

9566. What quantity of water do you throw on per acre? That I have not yet ascertained. The engine has not yet been tested even for twenty-four hours; it has only been going occasionally.

9567. You said you could not advise the diversion of the Murrumbidgee except in case of floods: do you know the discharge for every foot of height? No. Diversion.

9568. Supposing the discharge were equal to 800 cubic feet a second, would it not be a pity not to use the water to the greatest height possible? I think so. Discharge.

9569. Then you think we ought to take as much advantage of the water in the Murrumbidgee as possible? Yes, I certainly do. That is one reason why I have gone in for an engine and pump.

9570. *President.*] Was any attempt to carry on pumping made by your predecessor? Yes. Pumping

9571. What was the nature of it? He got an engine and pumped, and tried to carry the water back by flumes and drains.

9572. What horse-power was the pump? I could not say; it was only a small pump. Power.

9573. Did he succeed? No. Result.

9574. What was the reason of his failure? It was principally owing to the want of proper levels and the smallness of the pump; the pump was unsuitable for the purpose.

9575. Do not you think that, before entering upon any irrigation work of this kind, a person going into it on a large scale should have the ground thoroughly levelled and everything put on a proper basis before he starts? Yes, I do. Levelling.

9576. He should not go into it as some have done, in a haphazard sort of way? I quite agree with you.

9577. *Mr. Gipps.*] Who is the maker of the pump? Robey, of London. Pump.

9578. Has it any steam injector attached to it? That I could not say.

9579. *Mr. Donkin.*] How do you start it—have you to fill it with water or do you inject steam? It is filled with water in the first instance.

9580. *Mr. Targett.*] Have you irrigated for garden purposes? Yes, in a small way. Garden irrigation.

9581. With good effect? Yes.

9582. Have you trees old enough to judge of the results? Almost every one on the river has a garden dependent on irrigation.

9583. Fruit grows well, I suppose? Yes. Fruit.

9584. *President.*] Is there not a watercourse going out of the Murrumbidgee on your run where water goes in flood-time towards the Edwards? I am not aware of it myself, though I imagine that the flood-waters would go across from the Murrumbidgee to the Edwards.

Mr. John Dill recalled and re-examined:—

9585. *President.*] I understand that you wish to give some further evidence? There are one or two things I forgot in speaking of the creek that runs out at Toogimbie Station. We have two dams on that creek. After a flood these dams would last (say) from nine to twelve months, but it is the thorough soaking the ground gets that causes the water to remain so long. The soil is of such a porous nature that after an ordinary rain the water disappears altogether; for instance, I attempted without prospecting to make an excavation at the back of a dam, and after going 2 feet from the surface I got coarse drift sand in the bed of the creek. Mr. J. Dill. 31 July, 1885. Soil.

9586. That leads you to suppose that there is a drift running out towards the Edwards? Yes. Drift.

9587. And that, as a matter of fact, the Murrumbidgee is losing a large quantity of its water? Yes. Another matter I wish to mention is this: the flooded land I suppose extended for 30,000 or 40,000 acres, and when we purchased, it was thrown out as a great inducement to us that this country by being flooded by the Murrumbidgee would carry more stock than might otherwise have been expected. It was stated that it would carry a sheep to an acre, or an acre and a half, but as it has been for the last four years it takes 6 acres to carry a sheep, and last year 20 acres would not support a sheep; indeed I had to take all the sheep away. I had only 3,000 sheep on the whole of our frontage last season. My reason for referring to this is, that when I said I would not object to the water being taken out of the river I did not think it would injure those lower down the stream by the surplus water being taken away; that is, a certain portion of the water, not the diversion of the whole of the flood-water. Waste. Flooded land. Sheep per acre.

9588. Do you think that sufficient reason for not making a great deal of the back country of the Colony available for occupation? No, I do not.

9589. Because the diversion of the flood-water would mean that an immense area of Crown Lands would be made available by means of water? Yes. Crown lands.

9590. You do not think that the fact of two or three stations depending on the flooding of their land would be a sufficient reason for the Government ignoring those large tracts away from the river to which I refer? No, I should look upon that as a dog-in-the-manger policy; but those on the river have a great deal at stake, and should be considered as far as possible. I think those lower down have a right by purchase to the flood-waters; hardly any one down here and lower towards Wentworth would have bought but for the prospect of flood-waters. Right to flood waters.

Mr. Robert Wilson Ronald called in and examined:—

9591. *President.*] Where do you reside? Nap Nap. Mr. R. W. Ronald. 31 July, 1885.

9592. I think you particularly wish to give evidence? I wish to put before the Commission the nature of the country down our way, which is apparently a peculiar country.

Mr. R. W. Ronald. 31 July, 1885.

9593. Will you describe it? It is composed of what we call lignum swamps—not swamps, but a series of creeks one after another, with hardly any distance between them. You go half a mile and you find a creek; then, a short distance further on, two or three more within 100 yards of each other; then you go further and you find a similar state of things. It is below the level of the river bank. I have not been very long in the district, but one year it was all under water, except at very high points. The lignum country is such that unless it were levelled all the water would simply run down the creeks.

Lignum swamp.

Soil.

9594. What is the nature of the soil? It apparently expands and contracts with the moisture and heat. To show what I mean, when the dams are dry and the ground is exposed to the sun the banks crack, and the cracks go right through; the soil is like soap—it melts in the water and will not settle. We find that at high-flood times the banks will not stand—they are bound to go.

Cracks.

9595. Is that so with the dams on the ana-branch? Yes; there are big cracks in the dams, and we have to be constantly doing them up. It is not so much the dam itself sometimes as where it joins the sides.

9596. It breaks away around the ends? Sometimes it goes right through the crack, being in the middle of the dam. In enlarging the capacity of the dams we have often come upon drift sand and white sand.

9597. Is the surface soil retentive? Once it is soaked, but it has such cracks that for hours you will see the water running down through them.

9598. Then that would show the necessity of always keeping the dams tolerably well filled? Yes.

Extent.

9599. What extent of country is there from the river? From 80,000 to 100,000 acres of flooded country.

Floods.

9600. Does it require a high flood to cover much country? Yes. We have not had a flood since the last great flood to do much more than flood the immediate neighbourhood of the river and to run into some creeks. The last flood to cover most of the lignum country was in 1879.

Irrigation.

9601. Have you attempted to irrigate at all? We have not.

Pumping.

9602. Have you pumped water from the river? We have for garden purposes.

Result.

9603. With what result? Very good results, with plenty of manure.

9604. It produces everything you require? Yes.

Damming of Murrumbidgee.

9605. It is said that from the porous and peculiar nature of the soil it is necessary that the tanks should be kept filled—do not you think that that could be accomplished in a great measure if the body of the Murrumbidgee were kept fairly filled by means of dams which would keep the water at a certain height—would you not have water oftener then? I expect that the dams would break away; that would be the difficulty which would have to be contended with.

Tank-filling.

9606. You say that the country away from the river is lower than the river banks—if, then, the water was kept fairly up to the banks of the river, means could be adopted by which you could fill your tanks whenever you chose? We do not depend upon the dams for the supply; the dams we put on the creek are simply to get the water if we can. The actual bank of the river forms a lip, and the fall behind that is so slight and the ground so cracked by exposure to sun that a year or so back, after a slight rise in the river, and when it began to fall, it took water a fortnight to run 6 or 7 miles along the creeks.

9607. If you could get the tanks filled in that way would it not make the country much better? If we could rely on them being always filled we should have the flood-water over the lignum country, but I do not think the water itself would be necessary. We do not rely on our dams on the lignum creeks for permanent water. Our tanks on hard ground filled by rain-water are our standby, together with our wells.

Stock.

9608. The more the water is distributed the more stock you can carry? Yes; but we find that we have no difficulty in catching rain-water; we have these hard plains interspersed with this country, but one corner of our run is quite a dry country.

Gum Creek.

9609. Does water break out of the Murrumbidgee and go towards the Edwards? Yes, by Gum Creek—I think that is the name of the creek; in 1870 it ran and joined the Edwards.

9610. Where? Below Moulamein. It has evidently been a river, channel or an important channel of the river, at one time; wherever we have sunk there we have always come upon pure sand; we have tried to sink tanks there several times.

Lakes.

9611. Are there any deep indentations in the shape of lakes on your property? Yes, there are swamps which we think could be filled.

Depth.

9612. What depth of water would they contain? I should say you could fill them to at least 10 feet—I dare say more; there are higher parts of ground alongside; I do not know how the levels are.

9613. Have you carried out any works to fill any of these reservoirs? No, there is only one which I think would be of any importance.

Water storage.

9614. Have you made provision for the storage of water except by dams across small creeks? No.*

Diversion of Murrumbidgee flood-waters.

9615. Do you think that the diversion of a portion of the flood-waters of the Murrumbidgee at any point would be injurious to those residing down the river? I think it would be injurious to us; we are so dependent on the flooded country for feed, and if that country does not get flooded or there is not very heavy rain—and as a rule a flood follows heavy rain—there is very little grass at all; there are many acres there which would not carry a sheep.

9616. If that is conceded, nothing ought to be done to interfere with the flood-waters higher up? We should not approve of any diversion of the flood-waters.

9617. But as a national question do you think it is desirable that the flood-waters should be allowed to run to waste as they are doing at present? If they could be stored with advantage to everybody it would be much better to do so.

9618. You say that you are dependent upon flood-waters for the growth of grass, and if the waters were diverted they would not run over your property? Then we should suffer; we do not get a flood every year.

9619. Do you think that that is a sufficient reason why the flood-waters should not be diverted? In my opinion it is, but it is a personal matter with us there altogether; when I went into the station it was on the strength of the floods that I had anything to do with it.

Yanko Creek.

9620. You have heard of the proposal to divert water from the Murrumbidgee into Yanko Creek? Yes.

9621. Do you think that that would interfere much with the flow of the river? I think it would. The river is very low in summer; we hear reports of its having been dried up once, but that was a very long time ago; a man could walk across it without wetting himself up to his middle in the summer-time.

9622.

* Note (*on revision*):—The answer to this question is not correct, as we have excavated a large number of tanks on hard dry ground, besides five wells which were sunk before I came on the station.—R.W.R.

Mr. R. W. Ronald. 31 July, 1885.

9622. Do you know the quantity of water which would be diverted into the Yanko by the carrying out of such a project? No; if it is a matter of pumping I do not think there would be any harm in it; I cannot approve of any interference with the channel. I understand that something was done with the Yanko years ago; whether that made any difference I cannot say.
9623. Suppose that not more than 1-125th part of the water were diverted at any time from the river, do you think that that would interfere materially with the flow of the water? No, I do not.
9624. That is actually the proposal—you do not think that that would do any harm? No.
9625. Provided that the river were kept full by dams all the way down, do you think that that would be an improvement on the present state of things? I do not see where the improvement would come in; we should only use the river for watering stock, and we do that now. Effect of use of water on state of river.
9626. Supposing there were others who used it for irrigating purposes, for the production of grass or fodder, do you think that the conservation of so much more water would be for the benefit of the people residing along the river? I doubt whether they could pump enough out to make any great difference in the river.
9627. Supposing every station erected machinery? I don't think that one pump at every station could make any difference.
9628. Then you do not object to the pumping which is carried on? No, and certainly the question of navigation is of interest to us, because we get all our supplies up by river; when we have a high flood we cannot get our wool away by river, but when we have a moderate flood we send our wool by the Murrumbidgee. Navigation.
9629. But if at any time the railway to Hay is extended to Menindie or Pooncarie you would not send your wool by water then? Unless we could take it to Melbourne we should send it by river.
9630. Putting the question of navigation side by side with irrigation, do not you think it would be better, rather than not utilize the water at present running to waste, to run cheap railways instead of navigating the river? I think it would be very advisable to run cheap railways.
9631. So that as a matter of fact navigation could be superseded? I do not think you could get railways down our way, certainly not a cheap railway.
9632. The railway must go close to your station? We are on the south side of the river; our shed would be 30 or 40 miles away.
9633. *Mr. Gipps.*] What length of river frontage has your station? 20 miles. River frontage.
9634. What use do you make of this frontage for water supply—do you use the water for stock? The sheep go down to help themselves. The river is also a natural boundary. Use of it.
9635. You only use the water for supplying stock? Yes.
9636. If they were supplied by any other means you would not be under any disadvantage? There is one thing very certain—the sheep do very much better when they take the river water; I do not think they could be supplied in any other way.
9637. Would you be under any disadvantage if they could? I think so; it might not hold in the lake; if you diverted the river altogether there would be no floods—that is where we should lose.
9638. Is the slope of the country towards the river or away from it? Away from it, with a very slight fall. Slope.
9639. You were saying that you could not get the dams to hold: have you any gravel in the neighbourhood? Gravel. None.
9640. Sand? There is that drift sand, and sand lies on the plains. Sand.
9641. How many acres are required to feed a sheep in a good season? 3 at least. Sheep per acre.
9642. In a bad season? About 8 or 10 acres.
9643. Have you suffered much during the late drought? Very much.
9644. Did you lose much stock? Yes. Loss of stock.
9645. Was that due to the want of water or grass? Want of grass totally; we have wells on the station, and we were not short of water at any time. Wells.
9646. What depth are the wells? 70 or 80 feet. Depth.
9647. Do you get good water? Good stock water. Quality.
9648. What is the character of the strata? We have not put any wells down since I came on the station, so that I do not know. Strata.
9649. Is there any gravel or sand in the material thrown up? No gravel; there is a little gypsum.
9650. You always get good water at about 80 feet? Yes, it is good water.
9651. Have you any windmills? We work a windmill for the garden. Windmills.
9652. *Mr. Donkin.*] Have you found the water in any case to be poisonous? No.
9653. How do you raise the water? With whims and buckets. Raising water.
9654. You said that the floods benefited your run to a great extent; you depend upon flood-water then? Yes.
9655. What height is the water above summer level before it benefits you? It must be about 18 feet above summer level at Hay and 25 feet at Wagga Wagga. Beneficial river height.
9656. How would it affect you if water were taken down the Yanko 2 or 3 feet above summer level? We should not object to its being taken 2 or 3 feet above summer level.
9657. If about 1-100th part of the water in the river were taken you would not be at a disadvantage, because in a big flood you must get the water? Yes, it must come apparently.
9658. You said that you strongly objected to any water being taken out of the river? Yes, in an unregulated channel.
9659. That is, you would not like to see the stream entirely diverted? No.
9660. *Mr. Targett.*] You have no regular floods? No, they are not regular at all; we can never calculate upon them. Regularity of floods.
9661. I suppose that the river is never affected much by local rains? No, never at all.
9662. Are you backed up from the Murray at all? No water comes from the Murray.
9663. I suppose that in the large floods there is such an immense quantity of water coming down that even five or six channels as are proposed at the Yanko would not affect it. No.
9664. *President.*] What is the difference between the carrying capacity of flats flooded and not flooded, one season with another? Some of the country at the end of this summer would not carry a hoof. Carrying capacity of flooded country.
9665. Taking one season with another? That is rather difficult to say.
9666. Have you any idea what stock the land will carry in a flood and when there is no flood for a season? I can only hazard an opinion. I should think that without a flood the lignum flats would not, in a fair average season, carry more than one sheep to 5 acres, and I should think that every acre would carry a sheep after a flood.

9667.

Mr. R. W. Ronald. 31 July, 1885.

9667. Could not those flats be covered oftener if the river were kept full by means of dams? Yes, I fancy that could be done; but then the water might remain up too long for us.

9668. *Mr. Donkin.*] You say that you do not think there would be much advantage in putting up dams—but supposing all the station-holders were to use centrifugal pumps, would that not make a great difference? I hardly think that all the water which could be taken out by means of pumps would make much difference.

9669. Are you not aware that at Winbar Station, on the Darling, they nearly pumped the river dry, and it had to be stopped? There is a good stream down the Murrumbidgee. The difficulty with us is, that the climate is so changeable one year and another that you cannot depend on the state of the river.

Mr. Robert Macdonald, District Surveyor, called in and examined:—

Mr. R. Macdonald. 31 July, 1885.

9670. *President.*] Will you state anything you know connected with the underground water supply on the great ana-branch of the Darling? I saw the works, and wrote a report on them.

Works on great ana-branch of Darling.

9671. What works? The dams, by-washes, and channels, and a vast amount of works that have been constructed there. There is a cutting made from the main river to the ana-branch, and at intervals of about 7 or 8 miles dams were put up and by-washes were made to fill a lot of lakes which exist along the course of the ana-branch.

9672. What means were adopted to divert the water into those lakes? There are small watercourses running from the ana-branch, and the channels were deepened in a great many places, and dams were put below the junction of the watercourse and the by-washes; as soon as the lakes were filled, the by-wash was cut and the water taken on to the next place. The whole management of the ana-branch appeared to be vested in Mr. Cudmore.

9673. Who vested it in him? There are only half a dozen people concerned in the scheme, and I suppose he was appointed by common consent because he arranged everything and worked very hard in connection with the works.

9674. Have you ever been on the offtaking of that ana-branch from the Darling? No.

Receding of water.

9675. Do you know whether the water recedes when the flood goes down? It does—it goes back.

9676. Are any means tried to prevent that? It can be done by deepening, but I suppose that the effort has not been made.

9677. Could it not be done by regulating sluices? I am sure it could.

9678. Is that in your district? Yes.

Crown Lands.

9679. Is there any large amount of Crown Lands that would be made available if Government money were spent in conserving water along the ana-branch? I do not think there is; the only flooded country is the lakes.

9680. Supposing permanent water was made all along the ana-branch, is there any Crown Land that would bring in a return? It is nearly all Crown Land. I do not know that it would bring in a much larger return; it is only grazing country.

Quality of land.

9681. But it is good land, is it not? Very poor; it is low scrub and plain.

Wells.

9682. Have you had any experience of the underground water supply there in the wells along the course of the ana-branch? I have seen wells in the bed of the ana-branch; they were deep wells.

9683. What depth? 80 feet.*

9684. Was it along the course of the ana-branch or away from it? In the centre of the bed of the ana-branch.

9685. The soakage from the river? Yes, I suppose it was.

Quality.

9686. Was it good water? Fair water; it was brackish.

9687. Do you know whether water has been found between the ana-branch and the river by sinking? I do not think it has; they have gone in principally for tanks in that country.

9688. When was it? 27th January, 1881.

Cost of works.

9689. *Mr. Targett.*] Are those works pretty extensive? Yes, I think they are; they cost about £5,000, I believe.

9690. How many station-holders are concerned in them? Three only, I think.

9691. They have largely improved their water supply? Oh yes, immensely.

9692. Are those works permanent now? I have not seen them for five years; I have been away. They have had an awful season since; I imagine, however, that they are not dry.†

Surface of country.

9693. What is the character of the surface of the country between the Murrumbidgee and the ana-branch? It is perfectly level.

Nature.

9694. As regards the soil? A light clay.

9695. Is it retentive soil? Yes.

Slope.

9696. Is the slope of the country towards the lake? There is a very slight slope—it is almost a dead level.

9697. What is the depth of the banks on the ana-branch? It varies considerably, but on the average I suppose it is 15 feet.

9698. What is the length of it between the Murrumbidgee and the Darling following its course? I should think 200 miles; it is very crooked.‡

9699. In what seasons does the Darling flow into it? In September, but only in big floods.

Area of lakes.

9700. Do you know the area of those lakes and the depth? The depth, I should think, 20 feet on the average. The area is 20,000 acres. The area of some of them is even more than that. The Marie Lake is bad holding ground. They ran water out into the Multongay.

Embankment.

9701. Do you think they could raise the water in the lake higher than it is at present? Yes, by an embankment.

9702. And then could they apply that water to irrigation—is there any channel to lead it off towards the Darling? I think not.

Quality of soil.

9703. *Mr. Gipps.*] The soil is not worth much? No; it is very bad and mallee country.

9704.

---

* Note (*on revision*):—I find I was in error in stating the wells to be deep; they are quite shallow. The water obtained was the under soakage. I believe that in many cases the wells were less than 15 feet deep.—R.M.

† Note (*on revision*):—I have since learnt that they are nearly all dry.—R.M.

‡ Note (*on revision*):—On reconsideration I think the distance must be nearer 300 miles, but correct information can be obtained from Harbours and Rivers, or Survey Department, as the course has been surveyed.—R.M.

Mr. R. Macdonald.
31 July, 1885.

9704. What is the character of the immediate neighbourhood of the lakes? They are regular basins; on one side the banks are high, on the other the banks are low and ill-defined.
9705. So that there is shallow water on one side and deep on the other? Yes; you can walk half a mile into it before you get up to your neck.
Weirs.
9706. *Mr. Donkin.*] Do you think it possible to conserve water in the Darling by means of weirs? Yes.
9707. Do you know of any rocky beds in the Lachlan or Murrumbidgee that would afford good sites for dams? No, not one.
The Willandra.
9708. You were speaking of the Great Ana-branch as being largely used for supplying water: do you know of any other place where the water could be diverted from the Lachlan to the Darling to advantage? The Willandra would be a good place; water has been pumped into the Willandra before now.

Mr. Thomas Robertson examined:—

Mr. T. Robertson.
31 July, 1885.

9709. *President.*] You have resided in this district a long time? Since 1873.
9710. Have you seen any heavy floods in that time? Yes.
Floods.
9711. Did they cover any extent of country about Toganmain? Yes.
9712. Did it run any distance? It ran on through Gum Creek.
9713. How many miles out from the river? It runs 12 or 14 miles from the river, and a portion of it comes back again.
9714. I suppose that during times of flood you store water by means of dams? I have been storing in every way possible. I have been laying out large sums of money all over the country which I hold.
Watercourses.
9715. Will you describe the nature of the storage you have carried out? I have carried out every plan possible. I can describe it better by means of figures. This plan (*Appendix* FF 1) shows the watercourses by which the water flows from the Murrumbidgee towards the Billabong. I took levels by running water as far as my run extends, with small embankments through the hollows, and plough furrows through the ridges, till joining water running southward—some channels coming from an overflow higher up than Gum Creek.
9716. Do all these watercourses represent actual water in the country? They are only watercourses in flood-time; sometimes they are back water. The main course is the Gum Creek; it comes from the neighbouring run Kearbury, about 7 miles from my eastern boundary, and part of it runs back into the Murrumbidgee in large floods; it spreads over a good deal of country, and runs in flat channels nearly parallel to the river.
Gum Creek.
9717. You produce an estimate of the cost of irrigation? Yes; it is a copy of that which I sent to the Government when my run was divided.
Cost of irrigation.
9718. This list contains an account of 72 tanks and 15 wells, the cost of which was £29,680? Yes. (*Appendix* FF 2.)
9719. Have you adopted any means of filling the Gum Creek or any of those ana-branches? I have irrigated with a steam-engine for many years.
Steam-engine.
9720. Have you pumped water into any of those ana-branches or creeks? Oh, any steam power I could employ would be as nothing.
9721. You erected steam pumps many years ago? Yes.
Raising water.
9722. By which means you raise water for irrigation? I do.
9723. To what extent? I cannot do much. I have no great amount of steam power, nor if I had would it be of any effect—it would be merely playing at pumping.
9724. Then what course would you suggest? To let the surplus water overflow through the ana-branches.
Distribution by gravitation.
9725. That water should be sent higher up the river and distributed by gravitation? Yes. I think the Gum Creek ought to be opened to let the water flow. Back soakage would not supply such a river as the natural channel of the Murrumbidgee. The flood does overflow through the bends until the deep channel becomes almost still water. If engineers consider it practicable, I think numerous weirs should be formed in the bottom of the deep channel, not only for storage, but to carry light draught vessels over the snags.
Weirs.
9726. You think there are so many places where the water could find its way back by soakage that the people below would not suffer much? If I thought they would suffer I would not suggest it. You might lock the river, but it would be useless unless you had rocky bars. It is difficult to dam it; the whole river would be difficult to dam, and would flood most of the country on both sides, unless a get-away canal were made to send it inland.
Dams.
9727. You think that would be a good plan if engineering skill could show that it could be done? Yes; in one of my Manager's time he thought that an application would have to be sent in for the reservation of country for stock in time of flood; I could not see that, and I did not allow the matter to proceed. I have been endeavouring since to get all the water I could from everywhere. There is a plentiful supply at all points underground; it depends on how far you go.
Underground supply.
9728. Do you get good water? Good water generally.
9729. It will do for stock? Yes.
9730. Is it a general thing? It is in this country.
9731. How many years is it since you erected a pump? Mine is simply an engine watering a hay-field. I should not have had a crop for several years if I had not done that.
Irrigation.
9732. What extent is it? I have about 45 acres irrigated; the seed would not have sprung up if I had not irrigated.
Crops.
9733. Did you get any crop last year? I got two by keeping the engine going night and day during summer.
9734. Was it a good crop? It was for the soil; it does not happen to be a good spot.
9735. Do you think the cost of getting it is more than it is worth? Probably it is, but I was carrying on the experiment, looking at it in a large light.
9736. In what way do you look at it? In the way the Commission ask me to look at it.
Fodder.
9737. Have you any idea of growing any large quantity of fodder for stock in dry seasons? I have not had time to do that.
9738. Have you any idea whether it is practicable? I think it would be futile, owing to the want of labour.

Mr. T. Robertson. 31 July, 1885.

9730. The cost of raising the crop would be too much? Yes; the cost of raising, storing, and preserving would be.

9740. What is the cost of preserving? I had 150 tons of hay burnt at the very time that I wanted it.

Insurance.

9741. There is a means of insurance, is there not? It would amount to nearly the full value of the hay.

9742. Could not the difficulty be overcome by insurance? It might when operating on a small scale.

9743. You think that a man with a small holding could do it better? Yes; he is not subject to popular malice and things of that sort, and he has not to employ labour.

Artificial feeding.

9744. Have you ever made experiments in feeding stock? Not of artificial feeding; I have had too much to do otherwise.

9745. Have you any idea of the cost per head to feed stock artificially? No.

9746. Did they not feed stock last year at Groongal? Yes.

Cost.

9747. You do not know the cost? Mr. Mair gave me to understand, when we were comparing notes respecting stock which had travelled and stock which had been kept at home, that the cost of keeping them at home was about 4s.

9748. How long was that for? I could not tell. They began to feed with hay, but the rain came there much earlier than it did on my side of the river. Mr. Mair bought the hay very cheap, and he had the advantage of a railway siding on his run.

9749. It would cost him about 1s. a head per month? I think it would be more than that to me. I know that it was either three or four months that he was feeding.

9750. You say you were comparing notes with Mr. Mair as to the cost of feeding sheep at home and the cost of travelling them—what was the result? My own, I think, were a little cheaper than his, but I believe that the difference will be that my woolclip will be deficient in value.

9751. And did you lose more sheep? Yes, I lost 11 per cent.

9752. I suppose Mr. Mair lost very little? There was about the usual decrease I understood.

9753. Your books show something less per head; the difference would be made up by the loss in wool? That is a very uncertain calculation. The rains came to Mr. Mair earlier than to me.

9754. Actually there was not much difference between the cost of sending the sheep away and the cost to Mr. Mair of keeping his at home? I dare say there was not much difference.

Depth of wells.

9755. *Mr. Gipps.*] What is the average depth of the wells? Mostly under 100 feet.

Windmills.

9756. Have you tried windmills at all? I have tried them, but the only mill I had would not work when I wanted it.

9757. What was the size? Only an ordinary one at the home station. The drought put the mill out of the question.

Pump.

9758. How do you use your pump? I shift it about.

9759. Is it a centrifugal pump? Yes.

Lift.

9760. What is the height? I have lifted water at 27 feet.

9761. That is the highest? Yes, but it gives a very poor stream at that for the power used.

Discharge.

9762. Have you taken any record of the discharge of the pump at all? I cannot do that. I have a number of overground tanks, and I send out the engine and pump as much as 7 feet of water over the ground. That would flow in any direction, and I let the sheep water at it. During 1877, when I lost the great bulk of my stock, I had plenty of water that we conserved. It was want of grass that killed the sheep.

Power.

9763. What is the power of your engines? I have one 8-horse and one 6-horse power.

9764. You said you had 45 acres of ground irrigated? Yes, thereabouts, but a lot of it is bad soil.

Distribution.

9765. And do you cover it with water, or have you small trenches cut? I pour it in channels.

9766. Does the ground cake? No; the water is distributed by means of channels, and it is regulated.

9767. How long does it take you to pump enough water to cover the whole of it? I have not been so continuously at it as to be able to give a decided answer on that point. There are places where the ground seems to swallow up the water until it is full below.

9768. Does it take a week? It would take more than a week. I carry on all these experiments without reference to whether it pays or not.

Flooding.

9769. *Mr. Donkin.*] Do you try flooding the plains from the banks of the rivers for the natural grass? Yes; last year I kept the engine going night and day, but it was not good soil. There are a good many holes into which the water goes. Roly-polies spring up, and the cattle will not eat them, but they keep down the grass amongst the roly-polies.

Size of pump.

9770. What is the diameter of your pump? Only 10 inches.

9771. Do you not think it would have been more economical to have a larger pump? I dare say it would be more economical to me if the Government would turn the water over my run, but I have to do what is practicable.

Mr. Colin W. Simson, of Mungadal Station, near Hay, called in and examined:—

Mr. C. W. Simson. 31 July, 1885.

9772. *President.*] How long have you been in this district? Twenty years.

9773. Of course you know the Murrumbidgee from one end to the other? No, I do not; I have seen it in several places.

Garden irrigation.

9774. Have you attempted pumping water for either stock or irrigation purposes from the river? No; only for the garden.

9775. What is the result of it? We can grow almost anything we like if we use the water.

9776. When you pump water do you let it run on the land, or do you prepare the land to receive it? We used to have channels for the water to run along the trees. The Chinamen put on water with watering-cans for vegetables. The trees grow well and bear well, olives especially. They do remarkably well in this part of the country. I had two trees which were loaded. I believe we could grow any quantity of olives, but they must be watered.

Olives.

Preparation of land.

9777. In irrigating for grass, is it better to let the water run over the natural surface or to disturb the surface to receive the water? I have not had much experience in that. I think you would require to select flat pieces of ground or to make trenches along it.

9778. Do you think the water would cake the surface? I think it would unless the soil were suitable.

9779. Supposing on the hard red plains the land were scarified, would it not improve it very much and water it more effectually? On the flat plains we have often heavy rains. Two-thirds of my run was on

one

Mr. C. W. Simson. 31 July, 1885.

one occasion under water for months, and the growth of the grass was enormous that year. The grass was as high as this table all over the plains, and it was so strong and rough that I had a very bad clip of wool afterwards. It was too strong and too coarse—the stock did not thrive on it. It was the worst year I ever had on my place.

Supply in Murrumbidgee.

9780. Have you ever known the Murrumbidgee to be dry? No. I should say it is from 2 to 3 feet deep in the shallow places, and a good stream all the summer. My predecessor told me that he once saw the Murrumbidgee so low that you could hold the water in the palms of your hands. I do not think that will occur again. I think the stock having trodden the soil so much, more water runs into the river.

Stone.

9781. What is the nature of the bed—is there any rock? No, there is no stone within 50 miles of Hay.

Dams.

9782. Do you think it objectionable to try and fill the bed of the river by means of dams? I think it would be very useful to conserve the water if it could be sent out on to the plains.

9783. And do you think it possible to dam the river? Mr. Gordon, the hydraulic engineer in Melbourne, said there was no difficulty at all about it; but it seems to me that it would be rather a difficult job.

Wells.

9784. You have wells on your run—are they deep? The deepest, I think, is 108 feet, and the shallowest about 67. It does not matter what depth you strike the water it always comes to the same distance from the surface, so that in the shallowest well there is only 7 feet of water, and in the others 48. The best water I have is 20 miles out. You can get water anywhere, but it is not always fresh. On one occasion I sank a well 67 feet deep, and we could water a lot of stock at it; it went wrong, however, on the bottom; it had a sandy bottom, and the buckets always brought up a lot of stuff. I put down another shaft 50 yards distant. The first water was rather salt; the second well went down 108 feet, and the water was nearly fresh and very good. The water came up to within 60 feet of the surface, showing, though the surface is flat, the strata below are undulating.

9785. Then the water is artesian? Yes; it comes from a higher source, no doubt; it runs from east to west.

9786. What means do you adopt to raise the water? We do it all by horse-whims—we find them the best.

Yanko cutting.

9787. You have heard of the project to run water down the Yanko Creek? Yes.

9788. Do you think it would be detrimental to residents lower down the river? It depends on the depth the cutting went.

Sluices.

9789. If they went to within 2 feet of summer level, and allowed only 1–125th part of the volume of the river to flow in regulating it by means of sluices? I think there would be no objection to taking a certain quantity to a certain height above summer level; I should say it would be a fair thing, so long as navigation is not interfered with.

Navigation.

9790. Do you think the navigation of vital importance? It is till the railway gets further; it is not with me now, but down the river they are entirely dependent upon it.*

Irrigation in Spain.

9791. Do you think the interests of the people living lower down are so great that the flood-waters of the river should not be dealt with in some way as far as possible? It seems a great waste of power no doubt to let all the water go down to the ocean, but I am not prepared to say what should be done. It is a most difficult thing to regulate the supply of water from the river and dealing with the rights of owners. I see that in Spain they have a system of irrigation managed by a Board of owners. They distribute the water, and each man pays for what he gets. When I passed through Spain years ago it was just such a season as we have had here—some parts of the country were parched; but I came across a place near Valencia where a marvellous change had been effected by means of irrigation, the country looking beautiful. We passed through miles of orangeries and orchards where abundance of fruit, including olives, were grown. There were large numbers of steamers lying in the bay ready to take the oranges away. The fruit was all raised by irrigation, and you could see the water running through channels from one patch to another.

Conservation and distribution.

9792. Do not you think the proper foundation to work upon for the distribution of water is to conserve it at the heads of the streams as much as possible and distribute it by gravitation? I think so. What I should like to see would be the water above the level of the plain. I think it would be of no use to have it below the ground. Labour here is so expensive; in Egypt they raise it all by hand labour, but here of course it would be of little use to attempt it except for small areas.

9793. Then you approve of the conservation of water higher up, and of its being brought down by gravitation along the higher ridges of the country? That is the only way it could be done to be of any great benefit. It would be expensive, but I think it would do a great deal of good to the country. I have always taken a great deal of interest in irrigation; it seems a pity to see the water being lost. I met a Captain Galton, an eminent engineer, in London, one of the Board which has been appointed to examine the Hawkesbury railway bridge plans, and he told me, when I took a map of the country to him and explained the extent of the floods, that the flood-water would require to be taken off up near the source; he said we must take off the flood-water there, or the whole thing would be knocked to pieces.

9794. Then his scheme would be to divert the flood-water at the head of the river? Yes.

Report on irrigation in Lombardy and India.

9795. I think you told me he advised you respecting some works? Yes; I cannot remember it; I think it was Captain Baird Smith's works; he was an engineer appointed by the English Government to report on irrigation in Lombardy, and he afterwards reported on that of India. There was one good part in it; the irrigation schemes and canals of India now pay 1 per cent. to the revenues of the country, after paying interest of money and all expenses. There is another thing which I observed with regard to Lombardy—that the works never paid the men who formed them—they were always ruined—but the works paid future generations. The reason given by Captain Smith for Indian financial success was progressive scientific construction.

9796. *Mr. Targett.*] The irrigation which you have carried on was for your orchard? Yes, just for the house.

Growth of fruit.

9797. Will vines grow there? Yes.

9798. Would they grow without irrigation? They will grow with irrigation, but scarcely without it; I think they would nearly die out in a dry season.

Wells.

9799. *Mr. Gipps.*] What is the average depth of the wells? I have two wells between 60 and 70 feet deep, and others over 100 feet.

Strata.

9800. What are the strata? A kind of loamy, white-looking soil.

Bottom.

9801. What is the bottom? It is the same all the way down. 9802.

* Note (*on revision*):—I have not expressed sufficiently what I wished to say regarding the Yanko cutting, and wish to add that I had no objection to surplus flood-water being taken, and thought above navigation level a fair thing. Proprietors on the river consider it only a matter of time when they will utilize the water themselves, and therefore objected to transfer their riparian rights to parties who had no claims on the water.—C.W.S.

Mr. C. W. Simson. 31 July, 1885.

9802. What is the cost of sinking? I think about £300 for a well and appliances.
9803. Do you think that this country would be available for Abyssinian tube wells? There is nothing to prevent them from boring.
9804. Are you aware that it would be far cheaper to use them? I do not know; I think nothing is so cheap as the old whim.

Abyssinian well.

9805. But in sinking with an Abyssinian tube you would have a permanent well at once? I really cannot tell; I have had no experience of that kind of machinery.
9806. *Mr. Targett.*] Of course you line your wells? Yes, they are all slabbed.
9807. *Mr. Donkin.*] What is the deepest well which you know of in the district? I do not think that there are many deeper than those which I have mentioned.

Depth of wells.

9808. Do you think that a deep well, 1,000 feet deep, would strike artesian water? I do not know.

Test bore.

9809. Do you think that it would be advisable for the Government to put down a test bore to the bed rock? I think that it would be a good thing to do; it would do no harm, and it might do a great deal of good to have the ground tested. At Mossgiel, at my brother's late station, they had gone through the rock before striking water—a kind of slaty-looking stuff.

Olive-growing.

9810. You were speaking of olives growing; do you think that it would pay to irrigate to grow fruit? It is very successful in South Australia, and I do not see what there is to prevent its being so here. In Europe there are hundreds of miles of olives; I was told that the value of the fruit of an olive tree was from a dollar to £1; I believe there was as much fruit on each of my olive trees as there was on four of those which I saw in Europe.

Mr. John Furness called in and examined:—

Mr. J. Furness. 31 July, 1885.

9811. *President.*] What is your occupation? I am always on steamers on the river.
9812. Have you been here many years? About seventeen.
9813. Are you acquainted with many rocky bars on the river? Yes.

Rocky bars in Murrumbidgee.

9814. Will you tell us where they are? There are a good many. There is a reef of rock about 40 miles below Wagga Wagga, and another at 70 miles at Goomien Station; the next is about 20 miles above Narrandera; there are no more from there to Narrandera, but from Narrandera to Balranald there are some; about 3 miles below Balranald there are some, and about 3 miles from the Murtay there is another reef in the mouth of the river; these are all the rocks that I know of.

Do. in the Murray.

9815. Are you acquainted with the Murray from Albury downwards? Not from there, but I am from Echuca to Wentworth. There is a reef of rock about 14 miles below Echuca—the Murrumbidgee Reef we call it; then there is the Waradgery Reef below Camm's Island; then there is another reef below a place called Cuttybuck, and then at the Bitch and Pups; there is no other reef then until you get down, I suppose, about 20 miles below the mouth of the Murrumbidgee; there are reefs of some sort nearly every 3 or 4 miles through to Wentworth.
9816. Have you been below Wentworth? No.
9817. Have you been up the Darling? Yes.

Do. in the Darling.

9818. Are there any reefs there? Yes, but I do not know the names of them; 80 miles up the river from Wentworth there is one at a place called Hannan's Woolshed; there is another about 20 miles higher up, and another about 40 miles below Wilcannia; there is another about 10 miles below Wilcannia, and another just below the town; there are a great many more that I cannot remember.*
9819. You have traded up and down the Murrumbidgee for many years? Yes.

Water height in Murrumbidgee.

9820. Do you recollect the lowest state to which you have seen the river? About nine years ago; that was in a dry season.
9821. How high was the river at that time at the shallowest place? I should think about 50 or 60 feet wide, and 3 or 4 feet deep from Narrandera down.
9822. You do not know of any place where it was lower or narrower than that? No.

Springs.

9823. *Mr. Gipps.*] Have you noticed any springs about the Murrumbidgee or Darling? Yes.
9824. Were they strong springs? Yes, you could see the water running out from the bank of the Murrumbidgee.
9825. Are there many of those springs? I have seen them in different places.
9826. Have you seen any of those springs on the Darling? Yes; they are similar to the others, but a little stronger; you get patches of green grass here and there where the springs are.
9827. Do the springs last through the worst seasons? Yes; in fact in the dry seasons I have taken my horses to these places to get a little green grass for them; you go right up to your knees in the soft mud.

FRIDAY, 20 *NOVEMBER*, 1885.

At Sydney.

Present:—

Mr. DONKIN, J.P.,	Mr. MURRAY,
Mr. GIPPS, C.E.,	Mr. M'MORDIE, M.I.C.E.

J. B. DONKIN, Esq., in the Chair.

Mr. Robert Barbour, M.P., called in and examined:—

Mr. R. Barbour, M.P. 20 Nov., 1885.

9828. *Chairman.*] You know the Riverina District well? I know it well, from the Billabong right down.
9829. How many years have you been resident there? About seventeen years.
9830. Principally on the Murray? Yes; from Albury to the junction of the Edward and the Wakool Rivers with the Murray.
9831. Do you know the Murray about Howlong and Corowa? Yes.

Long Hollow.

9832. Do you know whether, at any time of high flood, the water of the Murray found its way across to the Billabong at Jerilderie by what is known as the Long Hollow and Jerilderie? I do not know that district

---

* Note (*on revision*):—I forgot to mention a certain place on the Darling called the Christmas Rocks, 122 miles above Menindie. These are the largest rocks between Wentworth and Wilcannia.—J.F.

district so well as further down. I think it is possible, and it has often struck me as a matter of great importance to examine the country between Albury and Corowa, in fact the whole of the Murray on our side, with the view of taking water out of the river at flood-level. Mr. R. Barbour, M.P.

9833. *Mr. Gipps.*] Only at flood season? I would only suggest it at flood season, because the river is then a great many feet higher, and available for carrying by channels into the interior between the Murray and the Murrumbidgee. 20 Nov., 1885. Diversion from Murray.

9834. *Chairman.*] The whole of that country, from Corowa to the Billabong Creek and down to its junction with the Edward River, is all level country? All dead level. Level country.

9835. Is there any ridge dividing the waters between the Billabong and the Murray? No important ridge. A race could be easily formed leading the flood-waters of the Murray to the Billabong. Ridge.

9836. You think that is possible? Quite possible.

9837. Would not that confer a great boon on the residents of that locality? A very great boon, and it would throw a permanent supply of water into the Billabong that is now almost dry. Permanent supply.

9838. In carrying out such a work, would it be necessary to place a weir across the Murray, or would you take the water only in flood-time? I would take it only in flood. The flood season in the Murray is generally from September to the latter end of December. The Murray differs from all other rivers in New South Wales in the respect that its waters are supplied by the melting of the snows in the mountains. When there is a great deal of snow there is more water in the Murray, and when there is less snow there is less water in the Murray. The months I have named are the navigable months. I have had much experience in this matter, as I had steamers trading on the Murray. It is during these months, I think, that the attention of New South Wales should be directed to taking water from the Murray, and if taken during these months no objection could be offered at all by parties living below. Weir. Source of Murray.

9839. You think that at present during these months there is a great waste of water? An enormous waste; you would be perfectly astonished at the amount. The Murray may be said to be at an average of something like 15 feet above summer level, with a width of upwards of 200 feet. That volume of water is flowing during the whole time from September to December, to waste to the sea. Waste of water

9840. After those months what is generally the normal height of the river? We call it after December not navigable, that is the summer level. Normal height of river

9841. To what point would it be not navigable; that is, how far can you navigate up the river after December? It would be dangerous to attempt to navigate after December. When it comes to summer level the boats have to be laid up. Navigation.

9842. That is not for the whole river? Yes, unless rains come to swell it.

9843. Are you speaking now of the river above Moama and Echuca? Both above and below.

9844. I think it is generally considered that the Murray is almost navigable for small steamers all the year round as far as Echuca? No, it is not navigable after Christmas, as a rule, unless a heavy fall of rain takes place to swell it. Immediately after Christmas it goes down, and then it is dangerous to attempt to run upon the river. The vessels only draw from 4 to 5 feet of water, and if you attempt to go any distance you are sure to run against a sandbank or a snag.

9845. Which Colony, as a rule, makes most use of the river for navigation? Victoria.

9846. To a larger extent than New South Wales? Very much larger.

9847. Do you think there would be any opposition if New South Wales were to block the river or take water off? I expect there would be. The Victorians are more progressive than we are. They have made a great many preparations, and are now ready to draw water off, and if they are prevented no doubt they will make objections. Objections blocking the river.

9848. They have taken a great quantity of water at Gunbower? Yes, they have been using the water for a long time.

9849. You do not look upon the Murray as of great use to this Colony for the purposes of navigation except when the snow-water is coming down? No, it is not safe to attempt to run vessels after Christmas. Navigation.

9850. The Murray is the largest stream and the most reliable of any of our rivers for navigation? Yes, and for an abundant supply of water. Supply.

9851. We have it in evidence that the flood-waters of the Murray found their way at one time to Lake Urana: do you think such a thing is possible? I think it is quite possible. In extremely high floods I have seen the Murray miles wide covering land that is not covered in ordinary seasons. It is possible that in the flood of 1870 the water may have found its way into Lake Urana. Urana Lake.

9852. You heard it mooted, I dare say, the possibility of cutting a canal from Deniliquin to Hay? Yes. Canal from Deniliquin to Hay.

9853. Do you think such a scheme is possible? I could not say. The country is very favourable for it, but everything will depend on the levels. If your starting-point, Moama, is as high as Hay there would be no difficulty. The country intervening would be very favourable to the formation of a canal—it is all dead level. If I had the railway time-table I would know the height of the railway at Albury.

9854. We have it here: it is 490 feet at Albury, and at Deniliquin 283; Moama is 315, and Hay is 304? In that case the project would be favourable. Levels.

9855. You know the Edward River well? I do. Edward River.

9856. A large volume of water passes down it? Yes.

9857. Do you think the current there is equal to the current in the Murray? I do not think it is quite so strong. It is the Murray which supplies the greater quantity of the water that goes into the Edward. Current.

9858. Entirely so, is it not? Not entirely. There is the drainage, and all those creeks which lie between the Murray and the Billabong go to supply the Edward, but the greater part of the water comes from the Murray. Supply.

9859. Do you think anything could be done with the Edward River, by locks or weirs, to hold the water back? I think it is very favourable for that purpose, without injuring any interests. Weirs.

9860. Of course now the water in the Edward finds its way into the Murray? It goes down 200 or 300 miles from where it comes out of the Murray.

9861. What is the average depth of the Edward? When it goes down to summer level there are places where you could wade across. Depth.

9862. What do you call summer level? Summer level is the level of the river between the 1st of January and the winter rains, which come usually in that quarter about May or June. Summer level.

9863. Still, it is a matter of doubt—it is an arbitrary level in the minds of different people? Yes, there is nothing

Mr. R. Barbour, M.P.

20 Nov., 1885.

nothing fixed. In a dry season you can wade accross the river; in a moist season the river rises 2, 3, or 4 feet.

9864. The Billabong joins the Edward about Moulamein? Yes.

9865. Have you seen the waters of the Edward join the Billabong? Yes.

Dams on Billabong.

9866. Is not that a rare occurrence? For some years back, owing to the construction of very large dams by the pastoral tenants in the neighbourhood of Jerilderie, the water has been stopped and does not run below that point, but formerly it used to run right through until it joined the Edward at Moulamein.

9867. If a constant supply were kept up in the Billabong it would water a large area of dry country? It would water a very large area of very dry country and very rich country.

Diversion to Billabong.

9868. Which do you think would be the more practicable scheme, to tap the Murray water to supply the Billabong, or to take the water of the Murrumbidgee down the Yanko? The best scheme is the Murray; having the largest supply, it would give the greatest volume of water.

Expense.

9869. Could it be done at no great expense? I believe it could. My idea would be to survey the Murray from Albury down to about Morrocca Station, that is where the Gulpa comes out.

Fall.

9870. You know there is a considerable fall from Albury to Jerilderie? Yes; according to the railway time-table it is about 40 or 50 feet, I think.

9871. Is it practicable to take the water across there? Yes; I would recommend such a scheme to be surveyed. I believe two or three watercourses might be cut along there—two at any rate.

Soil.

9872. You know the character of the soil of Riverina, between the Murray and the Murrumbidgee, would you say it is permeable? I believe it is good holding soil.

Soakage.

9873. You do not think much of the rainfall actually runs away by soakage? Very little indeed; it mostly goes by evaporation. My idea is that watercourses should be cut at an obtuse angle, so as to run water from the Murray into the Billabong. One might start from about Corowa.

Tuppal Creek.

9874. Tuppal Creek comes out of the Murray? Yes, on a similar angle. It is when the Murray is in flood that the creeks are filled.

Wells.

9875. Do you think much dependence is to be placed on obtaining water by wells? I do not think so. I would rather favour a surface scheme. If the flood-waters which now run to waste were conserved, enormous quantities of water might be deposited all through Riverina.

Local Trusts.

9876. Would you be in favour of allowing the erection of overshot dams to a certain height in the Billabong and other creeks, under the regulations of a local Trust, or under the authority of Government? I believe that is the proper course to be adopted. If the flood-waters were brought into the Billabong and retained by a series of overshot dams, there would be a continual supply of water.

9877. Have you had any experience of the working of local Water Trusts in Victoria? No.

9878. Would you recommend any extensive scheme of water conservation being carried out by the Government or by local bodies? I believe the Government will have to do it.

The Murray.

9879. *Mr. Murray.*] You stated that between September and December, on a portion of the Murray, the water was 15 feet deep and 200 feet wide? Yes.

Velocity.

9880. Can you tell the velocity at that point? We generally reckoned it ran about 2 miles an hour. We find an obstruction equal to that in going down stream.

9881. *Mr. M'Mordie.*] You said 15 feet above summer level—the summer level would be about 3 or 4 feet? Not on an average. There are holes where there might be 15 or 20 feet of water, but they are exceptional. There is no permanent level that you can depend on. You may get on to a part where there is only a foot of water. Below Swan Hill there are two or three sand-banks that cross the river; they consist of a kind of hard clay. Sometimes there are not more than 12 inches on the reef, then you get into a hole.

Navigation.

9882. *Mr. Murray.*] Do you not think that the navigation of the Murray is a secondary consideration to the uses that the water might be put to in the way of irrigation? Quite a secondary consideration. I believe that we have gone into an age beyond canals.

9883. *Mr. M'Mordie.*] Canals for navigation you mean? Yes; I believe they can be best utilized for irrigation and the supply of water.

Water-rate.

9884. *Mr. Murray.*] From your knowledge of that district, do you think the people would be glad to get a water supply such as we have foreshadowed, and pay a rate for the water? I believe they would be ready and willing to pay for the supply.

9885. And that under Water Trusts they would be prepared to pay a fair interest on the money laid out on extensive works to supply the water? I think they would. I would suggest simple works in the first instance; not to go into extensive works, or you might find the interest was more than people would be induced to pay. I believe it would be better to make cuttings as I have suggested than to put expensive works in the shape of weirs on the river, to secure a doubtful summer supply. It would be better to be satisfied with the excess obtained from the winter supply and from the flood season from September till Christmas, now going to waste.

Diversion of flood-waters.

9886. Do you not think such works would be also beneficial in the way of averting floods, by diverting the surplus water? Greatly beneficial in that way. By taking off the surplus water the river could be kept full, the people below would have all they could make use of at present, and the surplus would benefit other people. I lived on the bank of the Murray for several years, and I had an opportunity of observing a natural channel formed, which ran enormous quantities of water into the Edward from the Murray. There was a patch of green sward on which there were no trees, and this was used by the timber-getters in bringing logs down to the vessels in the river. When the wet weather came on the ground was soft, and the dragging of the logs made grooves in the ground. The country is so level, and the river in flood seasons is so full, that the water ran into these ruts, and in course of time they so scoured that now in a flood season there is a river running out of the Murray 200 feet wide; and in crossing it we had to be careful that we took the proper place, and there the water was just awash with the saddle. The volume of water that was thus caused to run out of the Murray swelled the Edward, and now there is double the volume of water running down the Edward in the snow season than ran down a few years ago.

Main channel.

9887. *Chairman.*] Do you think it is possible for the Edward ever to become the main channel? No; it could be made so, but it would not by Nature. The outlet from the Murray has got down now to the hard clay. There is no scour now. The channel seems to be a very firm hard clay.

9888. *Mr. Murray.*] It is only in flood-time that this outlet is open? Yes.

Mr. R. Barbour, M.P.

20 Nov., 1885.

9889. We gather from what you say that there is no definite watershed between the Edward and the Murray? The fall is all to the Edward.

9890. Almost from the very bank of the Murray? Yes.

9891. *Chairman.*] There is a fall towards the Billabong? Yes. The country is admirably adapted for conserving water and dispersing it afterwards. The Gulpa flows out of the Murray, and the opening of that creek was caused by the bogging of a bullock-dray in a manner similar to that in which the other creek was formed by the dragging of the logs of timber. The Gulpa does not run in summer, but only when the river comes to a certain height. The Gulpa.

9892. *Mr. Murray.*] Do you know anything of the quantity of water the Victorians are taking from the river? I do not know the quantity; I know they are doing so.

9893. Are they materially affecting the navigation of the river lower down? I do not think so. It is principally flood-water, I think, that they use. There are a great number of channels, and the Murray, when it is in flood, runs into these channels, and they make use of these for their irrigation schemes. You might take millions of gallons of water from the Murray during the flood season without inconveniencing anybody; that is, for several months in the year you might take a volume of water 15 feet deep and 200 feet wide. Murray floods.

9894. *Mr. Gipps.*] From what you have said I assume you would recommend that, previous to an instrumental survey of the river basins, by which alone a proper estimate of their full development can be formed, only such simple works should be constructed as would tend to allow of the diversion of the flood-waters for the benefit of the country? That is what I would suggest in the first instance. When living on the bank of the river I had ample opportunity of proving the great advantages of irrigation. I caused the gardener to cut a trench of 12 inches from the river, and when the water came to the brim it ran through the garden and then on towards the Edward. Within a few months the growth of the apple-trees was 6 feet, and the growth of the vegetation in the garden was beyond my expectation. Simple works. Irrigation.

9895. Do you know anything of the Merool Creek? Yes; that is beyond the Murrumbidgee. The Merool

9896. Do you know where it drains into? I could not say; I never followed it.

9897. Have you ever heard that the Murrumbidgee in high flood sometimes drains into the Merool? I believe it does. All that Riverina country can be very easily made to fall towards any particular point.

9898. *Chairman.*] You have been speaking of irrigation: do you know if it has been tried in Riverina for crops? Only lately. Within the last year or two, on the Murray, in my electorate, farmers have erected whims and horse-power works to pump water up to irrigate their crops, and they are so satisfied that every year they are adding to and increasing their means of irrigation. Irrigation.

9899. You think the Government should encourage irrigation schemes as far as possible? I believe so.

9900. Do you think it would be possible for farmers and graziers in Riverina, with a plentiful supply of water, to preserve sufficient fodder to take them over times of drought? Quite possible. Fodder

9901. *Mr. M'Mordie.*] And possible to sell fodder? Yes, to a large extent.

9902. At remunerative rates? At very remunerative rates. A small holder on the Murray irrigated a few acres of Indian sugar-cane, and he cut three crops in the year, yielding about 30 tons to the acre. The cattle eat the cane greedily. He is so satisfied with the result that he is going to establish a pig farm, and he expects to make a fortune out of it.

9903. *Mr. Gipps.*] Have you ever known the Murrumbidgee dry below Wagga Wagga? No. The Murrumbidgee.

9904. Is it always flowing there as a large stream? After the rainy season is over it dries up gradually until in some places it is not more than 2 feet deep.

9905. And what width? In some places from 15 to 100 feet wide. Width

9906. Would that be the lowest? There would not be a run of water of that width. The running of the stream in the summer months becomes less and less, until it is almost imperceptible.

9907. You would advise the same course with regard to the Murrumbidgee as with the Murray, that is, to avail ourselves of the flood-waters? Yes; but in the Murrumbidgee you do not get the same length of flood as in the Murray, because the floods in the Murrumbidgee are principally caused by rain, whereas the Murray flood-waters are caused by the melting of the snow in the mountains. Flood-waters.

9908. *Chairman.*] You have not seen many instances of rain-water being lost by percolation? No; the soil is very retentive. Before concluding, I might mention that a few weeks ago, at Moulamein, the water of the Edward River was backed up the Billabong 12 or 14 miles by an 8 or 10 feet rise in the Edward, giving a water frontage by the course of the Billabong of some 30 miles. From that I conclude that if an efficient and inexpensive kind of overshot dams were placed in the Billabong, at intervals of 10 or 12 miles, up to the source of supply of water from the Murray by the channel that I have said ought to be cut from the Murray, as high up that river as possible, say from near Corowa, there would be conserved a body of water—a continuous canal of water—of several hundreds of miles in length, of incalculable benefit to the Colony; and this, which would be supplied with running water from the Murray very often throughout the year, would be nearly equal to a continual running stream. Similar advantages will be obtained by the placing of overshot dams in the channel of the Edward River, although not to the same extent. Neither of these channels has ever been navigated beyond a few miles above Moulamein; that is, a small vessel has taken wool in the flood season from Wooroona Station, some 10 miles above Moulamein on the Edward River, but no higher, but no vessel has ever attempted the Billabong, so that no objections could be urged on the score of obstructing the navigation, and no expensive works need be constructed to provide for navigation. Percolation. Overshot dams in the Billabong.

MEMORANDUM

MEMORANDUM.

Evidence taken on the Lower Lachlan and Murrumbidgee.

To the Members of the Commission.

Gentlemen, Sydney, 13 August, 1885.

I have the honor to submit the following evidence, taken before Mr. Gipps and myself during our visit to the Lower Lachlan and Murrumbidgee Rivers.

I have, &c.,
WILLIAM JOHN LYNE,
President.

SATURDAY, 1 AUGUST, 1885.

Statement of Mr. J. L. Gwydir :—

President.] You are the manager of Corrong Station? Yes.
How many years have you been in the district? About sixteen years.
How long have you been managing this station? About two years.

Flooding. Will you tell us what you know in reference to the flooding of the country at the head of these works we are now on? Before we flooded the country by means of these cuttings we used to carry 4,000 sheep on the two paddocks, one of which was 5 miles by 6, and the other 6 by 8.

But before you flooded the country some of the sheep died, did they not? Yes, a great number of them.

Wool. And was the wool good on those that lived? No; the sheep were in bad condition, and there was a break in the wool.

Sheep carrying capacity. After the cuttings were made and the water was turned on to this country, how many sheep did you carry? 12,000, where we used only to carry 4,000.

Did the land carry them well? Yes; they came off in really good condition, and the wool was sound.

Flooding. How many floodings did you give the land? Two. When the cuttings were completed about twelve months ago we flooded it, and again in January or February last.

Area. What area or what proportion of land was actually covered with water? In one paddock 3 by 5 miles; in the other, 2 miles by 6.

Profit. Comparing the years when the land was not flooded with the years since, what has been the difference in actual profit? During the year before irrigation began, when the paddocks were dry, we lost from 1,500 to 2,000 sheep out of 4,000. The next year, when the paddocks were irrigated, we carried 12,000 sheep, the profit on which would be at least 3s. per head. The difference in profit in the two years was about £1,800, not reckoning the depreciation in the value of the wool of those sheep which survived in the first year, which would be at least 1s. per head. In addition, we fattened 125 head of cattle and over 200 head of horses.

Cost of cuttings. What was the cost of making the cuttings? £1,205 6s.

Mr. Gipps.] To what depth of water were the paddocks flooded? From 2 feet to 6 inches.

Duration of flooding. How long did the water last on them? The first time of flooding it lasted between four and five weeks after it ceased running, and the second time it remained longer, on account of the country being soaked. I dare say it lasted ten weeks.

Would less water have done than was actually put on? The higher the water came, the more country it irrigated.

There was no necessity to put 2 feet of water on the land? Not the second time, perhaps. The improvements were made in 1884, so that we have only had one season out of them.

Statement of Mr. G. E. Ashcroft :—

President.] What is your name? George Edwin Ashcroft.
How long have you been living in this locality? About seven years.
How long in Riverina? Twenty-eight years.
Where were you living before you came here? On the Billabong.

Area. What area of land have you here? Nearly 6,000 acres.

Irrigation. Have you attempted irrigation at all artificially? Yes; when the water breaks out, I check it and distribute it over the little creeks.

Depth of water. Have you any idea of the depth of water that runs over the land that you have flooded? From 4 inches to 2 or 3 feet.

Have you your country divided into paddocks? Yes.

Stock carrying capacity. What stock can you carry without flooding? Unless we have a great deal of rain we can carry scarcely any. The country is no good at all if not flooded. The rain does not seem to take any effect on it unless we have an extraordinary fall.

You have some paddocks you flood, and some you cannot? Yes.

What is the difference in the carrying capacity of the two? I can carry four times as many on the flooded country.

Is the country of the same nature? Yes.

Seasons. During last year was it a good season here? It was not a good season, but in spots where I had the land flooded the result was good.

Where it was not irrigated, could you carry anything? No; it was quite bare.

Irrigated area. What area have you irrigated? I must have irrigated about 2,500 acres.

What sort of feed had you over that? Really good; it was splendid where the water touched.

Stock. Did you run your own stock only? No; I took in stock also for other people. I had 1,000 sheep on the flooded country; 140 head of cattle of my own, 240 head of cattle grazing, and 450 horses grazing. This was during the summer months, from October till the middle of April.

That was on 2,500 acres? Yes.

What had you on the remaining 1,500 acres? There was nothing to eat, and the ground looked as bare as a camping-ground.

Profits. How much do you think you made off the 2,500 acres during the summer months? About £1,322 10s. Besides, I allowed about 100 head of horses belonging to neighbours to run in the paddocks free.

Duration of flooding. *Mr. Gipps.*] How long did the water last from the flooding? It came on early in September, and remained till about the latter end of December.

Height. What was its height? From about 4 inches to 3 feet. The ground kept wet from the soakage of the creeks.

Cuttings. Did you make cuttings from the Lachlan to cause this flooding? I did not make any from the Lachlan; I made them from lagoons filled by the Lachlan. A man on horseback with a shovel could make fifty or sixty openings in a day.

The ground would not have been flooded but for these cuttings? No, not at that time; and if there had been no cuttings the ground would only have been flooded to a small extent by the creeks.

You are still carrying on the work? Yes.

Fall of country. Is the fall of the country from the Lachlan or towards the Lachlan? The water almost all runs south towards the Murrumbidgee.

You have only completed about half your holding? Yes; I can extend to the other half the same benefits by means of little dams and cuttings.

System of channels. *President.*] What you have achieved is the result of a system of channels that you are cutting from the various lagoons that have been filled by the Lachlan? Yes.

You are continuing that system to bring the whole of your land under the benefits? Yes.

Statement

Statement of Mr. P. B. Moore :—

What is your name? Phillip Bennett Moore.
How long have you been here? Two years.
Where did you come from here? Yanga Station.
What is the size of your holding? My holding is 640 acres, and I have the renting besides of 1,280 acres from selectors. — Size of holding.
What is the nature of the country? Reed-bed country all of it, interspersed with gum timber. — Country.
Have you had water over it? The first year I had water over every inch of it, but last winter I had it over only about a third of the country; on my own block I had not 40 acres flooded. — Flooding.
What is the difference in the carrying capabilities of the land when flooded, and when no water has been on it? The first year I cleared over £1,000 from my own land, and the portions next; but last year, when we had only a partial flood, I did not take £500. — Carrying capacity.
How much was flooded the last year? Not a third of it. — Flooding.
How much the year before? Nearly all.
You graze stock only? Yes.
You do not cultivate anything? No; if I could afford to go to the expense of damming back the water I could grow tremendous crops on the land. — Crops.
Did you ever try to grow corn? Not on the flooded country.
Nor anything else? No.
What depth of water went over the land? On the lowest parts there was about 5 feet I suppose, and it decreased from that to nothing. The country averages about 18 inches of water over it. — Depth of water.
How long did the water remain on it? The first year, about four months.
You are just at the end of the reed-beds? Yes, about the southern end.
What becomes of the water that floods this country? It soaks quickly away underground. — Soakage.
In what direction does it go underground? I have no idea; I know we could get water anywhere in the reed-beds. In my own well here I struck the water at 15 feet. — Well.
It never goes dry? Never.
What kind of soil do you get the water in? A thick, gluey sort of sand. — Soil.
Does the water in your well rise and fall according to the flood? Yes. Last winter the level was not affected by the flood. As the reeds become dry and the water dries up, the well gradually goes back to its 15 feet level. It has never yet gone below that level. The year before last the water in the well was up to the top of it, and it gradually went away as the summer advanced. — Rise.
Mr. Gipps.] Do you use the windmill? Yes. — Windmill.
What kind of windmill? Althouse.
What is the diameter of the vane? 10 feet; but I would not recommend any one to purchase any smaller than 14 feet.
You find it answer very well? Yes.
What quantity of water can you pump with it? You cannot use more than an inch and a quarter pump.
Do you ever exhaust your well with it? Never; it does not seem to affect it.
What is the diameter of the sail? 4 feet by not quite 2 feet.
And the diameter of the pipe? An inch and a quarter.
Suction-pipe? Yes.
What quantity of water can you get by continual pumping? I do not know. I dare say I could get, by a good steady breeze all day, 5,000 or 6,000 gallons of water.
How many days in the week, in a hot season, does the wind blow sufficiently to use the pump? In the summer every second day. — Wind
Do you get a good breeze in the summer-time? Yes, plenty of wind to work the mill.
What is the prevailing wind in summer-time? North-north-east, or northerly.

Statement of Mr. James Tyson, junior :—

President.] What is your name in full? James Tyson, junior.
You reside at Tupra Station? Yes.
How many years have you resided here? On this and the adjoining station thirty-seven years.
You have known all the floods in the Lachlan during that time? Yes; except during eight years of the early part of my residence; during the last twenty-nine years I have known all the floods. — Lachlan floods.
Can you recollect about the time of the heaviest floods during that time? In 1852 and 1870.
Was there not a heavy flood in 1864? There may have been, but it was not so heavy as the others.
About what period elapsed between the floods? Sometimes we have floods every three or four years running in succession. — Periods.
And is there a series of years without floods? Up to the present we have never known more than two years without a good flood, but this time we have gone three years without; this is the longest period I know for twenty-nine years.
During the heavy floods you speak of, you knew creeks and depressions back from the river a considerable distance that were filled with water from the floods? Yes; on the north bank of the Lachlan, wherever you see box timber, you know flood-water has run there. — Places filled by floods.
The floods that occurred between 1852 and 1870 did not fill those places? They did not fill the outside places; in about 1875 most of these outside depressions were filled to a distance of 60 miles below Booligal, as also in 1864.
When did you commence any cuttings to lead water into the back country? In 1861. — Cuttings.
What cutting was that? From Lignum Lake to Boocathan Lake, a distance of about 4½ miles. — From Lignum Lake to Boocathan Lake.
When was the lake filled after that? I think within twelve months after the cutting was completed, as near as I can remember; Lignum Lake is filled by several creeks running from the reed-beds; Boocathan Lake is filled by a cutting made in 1861.
From the Lignum Lake? Yes.
What depth of water was in that lake? About 52 feet. — Depth.
It has never been dry since? No; it still has 4 feet of water in it. — Supply.
How long is it since any water ran into it? No water has run into it for two years, but for three or four years previous to that the cutting had so silted up that very little water used to come into the lake, and that is the reason why the supply is so small. Last year I cleaned out the cutting and made it wider than ever it was before, so a fresh coming down every three or four years will be almost certain to give sufficient water. Between 1861 and 1884 not more than £30 per mile had been expended in keeping the cutting in repair. — Cost of repairs.
What was the cost of that cutting? As nearly as I can remember, about £640 per mile; I may add that a small cutting had been previously made by the former lessee of Juanbung Run into Bunoombert Lake, where Juanbung head-station is now, but it was a failure; previous to 1861, and up to 1882, little or nothing was done to keep it clear; this was a small cutting 12 feet on top, with slopes, and it silted up. I then in 1883 made a cutting three times the size, that will stand good for twenty years. — Cost of cutting. Cutting to Bunoombert Lake.
Has that lake ever been dry since? Yes; because the cutting was not made large enough in the first instance, it was dry in 1883, but it held water for twenty years. — Supply.
And now the cutting is widened again? Yes; in the latter end of 1883 I deepened it, and now the quantity of water that goes into the lake is such that it will never be dry again.
When was the third cutting made? In 1864; that was leading from the Lachlan River, about three-quarters of a mile above Oxley township, to a lake called Cummachum; thence in a northerly direction 5½ miles into Box Creek. — From Lachlan to Cummachum Lake.
What was the effect of that cutting? A large supply of water ran through within about twelve months after the cutting was completed.
Has that lake ever been dry since? Not quite dry. — Supply.
What was the cost of the work? I have not made an estimate of the cost, but I have heard it was £14,000. — Cost.
What was the depth of the cutting? From 7 to 13 feet. — Depth.
What was the width? At the bottom, 12 to 14 feet, with a slope of 3 to 1. — Width.
What was the fall? A foot in the mile. — And Fall.

And there was the same fall to the other lake? Not less than a foot in the mile—in every cutting we allowed that fall; if the country gave more than that we had not to allow it in the work.

Cutting towards Mount Emu. What was the next work? The next work was a cutting commencing about 10 miles west of Bunoombert Lake, at the head-station of Juanbung, from a box swamp supplied by Lachlan water at the time of high flood, and running into a lake near Mount Emu. That cutting was about three-quarters of a mile long, about 3 feet deep, and about 14 feet wide. It was made in 1870.

The water did not go further than Mount Emu Lake? No; there was a regular basin there.

Depth. What was the depth of water? About 10 or 11 feet. There was a natural depression, and we thought to save a lot of water. In 1869 we made a cutting from Duckshot Lake into a lignum swamp east of that lake.

Duckshot Lake. Where did you take the water to in that cutting? From the swamp into Duckshot Lake, a distance of about 2½ or 3 miles. The cutting was about 14 feet wide at bottom, and about 2 or 3 feet deep. The water we got through into Duckshot Lake at that time came through Dry Lake on Walgiers run, and from the Lachlan River about 7 miles above Booligal, by the Merrimidgel Creek. The overflow above Walgiers Lake, which is the first to run, also joined these waters.

Cutting. How long did it take to come down that course? The cutting was made in 1869, and in the high flood of 1870 the water came down and filled the lake within two months. It took two months, because the cutting was so small.

Supply. What quantity of water was held in that lake? It is about three-quarters of a mile in diameter, and 32 feet deep in the centre, giving about half a mile flat bottom in the centre.

Dams. What was the next cutting? The next permanent work we did was a dam about 2½ miles from the Murrumbidgee River to a plain situate north of the bank of the river called Cockatoo Plain. The object of the dam is to force the water north and west to irrigate country. We have not received any benefit from that yet, as the floods have not been high since the dam was made.

In connection with that work, you have also dammed some creeks that allowed the water to run into the Murrumbidgee River? Yes; from that, which is about 6 miles to the junction of the Lachlan, I have a string of dams to keep all water from again going into the Murrumbidgee River. I have also a dam 3 miles long 2 miles south of the Lachlan reed-beds, crossing a number of creeks, to convey the water westerly to Cockatoo; it cost £600.

Cost. How much did that cost? Over £800, without the little dams; about £1,300 altogether.

Effect. What will be the effect of that? The effect will be to cause an ordinary flood or fresh to irrigate or flood something like 50,000 acres of land, besides forcing the water to a level in a north-westerly direction, so that we can again fill the lake at Mount Emu, which is about 12 miles north of the bank of the Murrumbidgee.

Cutting from Bullogal Lake to Ryan's Lake. What was the next work? In 1884 and part of 1885 we made a cutting from Bullogal Lake to Ryan's Lake, thence to Duckshot, about 10 miles. We also put a line of dams from Bullogal Lake to the Lachlan River, a distance of about 14 miles. We then made nine cuttings from the Lachlan River for 1 mile above that. These cuttings help the natural overflow 1½ mile above Reserve No. 106, Walgiers Run.

Size. What size are they? 2 feet deep, and from 20 to 30 feet wide.

Dam. Did you throw a dam across the Lachlan River below those cuttings? There was a dam previously, and we took advantage of it. There was a dam below the cuttings which raises the water whenever a fresh comes down, so that it will flow through the cuttings and get out on the north side of my line of dams.* If sufficient water is brought down in that way,

Box Creek. by putting a dam 5 miles below Duckshot on the same watercourse, the water can then be turned into Box Creek, which goes into the Murray somewhere near Euston. This watercourse was 300 yards wide at its narrowest crossing on Tupra Run in 1870, with running water 1 foot broad, 3½ feet deep. I put a bridge over at this place, and crossed 200,000 sheep. That

Bridge and channels. year this bridge was inspected by Mr. Road Inspector Philben. The effect of this work is, by a complete system of channels, and by damming up creeks that allowed the water to run back to the river after it broke out, to make a direct course for the water to Duckshot Lake, and prevent it from running back into low lignum flats that lie below my land, and absorb an immense quantity of water.

Filling of Duckshot Lake. By these means that you have adopted you are enabled to fill Duckshot Lake, I suppose, at any ordinary flood? Yes. Before that time, when the water came from Bullogal, and down from the Merrimidgel, there was no certainty of water in Duckshot once in ten years; now there will be a certainty once in three years, providing these works are protected.

Irrigation. Not only that, but there will be a certainty every year that from 20,000 to 30,000 acres will be irrigated on the upper part of these waterworks.

Cost. About what is the cost of this work from the outlet of the Lachlan to Duckshot Lake? For the full distance of 26 miles it is about £5,000. Of this length, only about 10 miles have been cut, as in some places the natural creeks have been utilized. The cost of the works at the outlet, extending over the first mile, is £460. The dams from thence to Bullogal Lake, £100 per mile, only damming main creeks.

You say there is a dam below the cuttings? Yes.

Dam. Does that dam keep permanent water above it? Yes.

By-wash. And at what height does the by-wash take the water off? At about 5 feet from the top of the bank. When the by-wash is running there are 3 feet of water in my cutting, and a depth of 5 feet running round into the river.

Size of cutting. What size is the cutting? 18 feet wide in the bottom, with a batter of 3 to 1.

Execution. You do it by ploughs and scoops? Yes. The deepest part is about 5 feet 4 inches, with a fall of a foot in the mile, and

Fall. any fall in the country added to that. In a part of the same work there is a fall of 5 feet in the mile.

Dams on Lachlan. Have you found any difficulty with the dams that are put across the Lachlan? Very little. The dams are provided with by-washes which come gradually in, and stand generally about five or seven years without much repairing. Sometimes we shut them up and make a fresh by-wash, but in no instance for twenty years have we had to abandon an old dam because there was too much by-wash.

Do you think that by a system of dams right down the river a large amount of water would be kept back in flood-time? Yes, it is quite practicable, because from Oxley to Booligal, a distance of 60 miles in a straight line, there are dams from every 4 to 7 miles. The first was erected in 1860, and the water throws from one dam to another.

Have you had any experience in connection with the Murrumbidgee? None, except in making cuttings out from the river to flood low-lying lands.

Dams on Murrumbidgee. Do you think it would be practicable to put dams across the Murrumbidgee? Quite so.

Bars There are plenty of bars across it? Plenty.

By that means the bed of the river would be constantly filled with water? Yes.

Carrying capacity. What increase do you estimate these works will make in the carrying capacity of your stations here? I think about 100,000 sheep.

Proportionately, I mean? Well, the country now carries threefold what it used to carry. When the whole work comes into operation, I estimate the carrying capacity will be increased at the rate of five to one.

Mr. Gipps.] From what distance below Booligal or Forbes have you had experience of the Lachlan River? From about 7 miles above Hillston to the junction I have a knowledge of the river on both sides.

Dams. How many dams are there in that distance? Ten.

Character. What is the character of the dams? Just mud dams across the river, 14 feet wide on top, with a slope of 3 in 1 on each side.

Height What is the average height? About 18 feet, I should think.

Are the dams higher on the upper part of the river, or *vice versa*? I think on the lower part the dams are slightly higher; there is a greater force of water down here.

By-washes What provision is made for by-washes? The dam is always put in the river at a place where there is at least a quarter of a mile of low land, which allows a natural flow of water from the river.

Water courses. Are there any natural watercourses by which the river is diverted? Plenty.

The Willandra What benefit are they to the country generally—do they extend any distance? The Willandra leaves the Lachlan River about 30 miles above Hillston, and flows in time of high flood almost to the Tallywalka, which leaves the Darling at Wilcannia. It runs in a north-westerly direction for 170 miles, I should say.

Channel In what kind of channel? A deep channel for the first part of the way—for 100 miles—then through box flats, and then the channel becomes broader.

Diversion Box Lake. Could the water be diverted into natural depressions or lakes? It does fill several box lakes on the way; it then spreads into Box Lake.

Size. What size is it? About half a mile in diameter, and it holds from 4 to 5 feet of water.

Do you know of any depressions which could be filled by it? Not any large ones. What

* Note *(on revision)*:—The 6 feet rise at Forbes, at present in the Lachlan, is flooding this country.—J.T., 12/8/85.

What is the next watercourse below that? The Merowie or Box Creek, which leaves the Lachlan 7 miles above Hillston. Merowie or Box Creek.
It runs north-west in the first instance, then west, then a little south and west until it enters the Murray near Euston, keeping out from the Murrumbidgee at a distance of about 40 miles.
What is the character of that channel? It is a deep channel for about 100 miles, and then it seems to have been silted up, and spreads a good deal into box lakes as the Willandra does. The channel, carried right through into the Murray, is a well defined channel. Channel.
Would that be available for any other depression? A great deal of good could be done by damming and spreading the water. There are depressions on the side all along that could be filled by cuttings, and they would hold about 10 feet of water. Depressions.
What is the next natural watercourse? The next one below the Merowie or Box Creek is the Merrimidgel, which leaves the Lachlan about 2 miles above Booligal. That also runs in a north-westerly direction, keeping about 10 miles south of the Box Creek. It goes on through a lot of lignum flats for a distance of 30 miles, to fill the Dry Lake and also Duckshot Lake. Part of the water then goes north into the Box Creek, and part of it south into the Lachlan River at Oxley. The water is divided at the Dry Lake. Merrimidgel Creek.
What is the character of that channel? A lignum flat, from ¼ mile to 2 miles wide all the way. The channel itself in the centre is about 4 feet deep, and about 30 yards wide. Channel.
Could that be used for any other lakes? The only advantage that could be derived from it would be to check it from flowing back into the Lachlan, and to turn it north to the Box Creek.
Are there any other natural watercourses? The Mucklebar, which leaves the Lachlan a little below Booligal, and comes on towards Walgiers Lake, which it fills in passing. It then takes a north-west direction, and joins the water that runs into the Dry Lake and Box Creek. The Mucklebar.
Could that be used for any other purposes? For nothing better than diverting the channel into the Box Creek. There are no natural lakes along that watercourse, and it is well defined until it comes to Walgier's Lake, being about 5 feet deep and 30 yards wide. When it reaches Walgiers Lake it is about 200 yards wide, and 2 feet deep, and covered with lignum.
This creek does not run unless we have a fairly good flood, say 12 feet at Forbes.
Could greater use be made of the water by diverting it or preventing it from entering Walgiers Lake? Yes; if it enters Walgiers it falls south into the Lachlan, or into useless lignum flats, and is lost. By keeping it out, great benefit is derived from it.
Is that one of your improvements? No; the water from my improvements joins that, in a 12-feet rise from Forbes.
What is the depth of the channel with regard to the bank of the Lachlan River, where it leaves the river? It leaves in a general flat, and forms into a creek when it gets away from the river. Channel
The next creek that leaves the Lachlan River of any benefit to the country is 1½ mile above reserve No. 106, and then runs in a direct line 1 mile wide to the north shore of Walgiers Lake; creeks abound all the way on the south, and when it reaches there it is called Peppermint Creek, because it runs past Walgiers Lake and fills another lake called Peppermint Lake. Peppermint Creek.
That does not fill Walgiers Lake? It fills it in passing. Mucklebar and Peppermint both meet, and a certain quantity of the water runs into Walgiers Lake, and the rest of the water flows west.
What becomes of the stream of those creeks? Before I made the improvements the water used to run south from the creeks into low, dead lignum flats, that held water from 3 to 4 feet deep, and as the river lowered the water gradually drained back into the river, leaving the country completely scalded through the water lying so long on it. But by means of a dam at every quarter of a mile, shutting off the creeks flowing south, the water is conveyed in a more direct course, and spreading northerly it irrigates country from half a mile to 2 miles wide in the whole distance. Walgiers Lake.
What is the area of Walgiers Lake? About 1,000 acres. Depth.
And the depth of it? When full, it will hold about 7 feet of water.
It would be merely an evaporating pan? It is not an evaporating pan; there are outlets on the south side which it fills and empties again.
There would be no advantage in filling the lake? No; we have dammed it to keep it dry, because it grows good herbage. Cummachum Lake.
How many stock do you water at Cummachum Lake? About 20,000 sheep every summer. Depth.
What is the average depth now? 5 or 6 feet.
The average depth full is 10 feet? Yes; from the time it was made till now we have watered 20,000 sheep all over every year through the summer months.
With regard to your experience of the Lachlan River, the general trend of the country is from the Lachlan towards the Darling? Yes. Trend.
And from the Murrumbidgee towards the Lachlan? No; from the Murrumbidgee towards the Edward. The Murrumbidgee waters drain south. The Mirool is the only water from the Murrumbidgee to the Lachlan. Between here (Tupra) and Coldwater, there is water which runs from the Lachlan to the Murrumbidgee. It comes in 5 miles below Maude. The tendency from the Lachlan 15 miles below Booligal is towards the Murrumbidgee. Above Hay, the Murrumbidgee water comes to the Lachlan; below Hay, it goes to the Edward. The Mirool.
Have you had any experience in wells? A good deal. We sank trial shafts through the salt-bush country, but we found salt water in every shaft. We tried in watercourses, in sand-hills, or plains, in fact in every character of country for about 40 miles north of the Lachlan River, and then beyond that we found fresh water. Wells.
At the same depth? Yes. Fresh water supply.
What was the average depth at which you got fresh water? From 140 to 170 feet.
Do floods in the river appear to influence the water? Not at all—the floods have no effect on it. These wells will water from 10,000 to 40,000 sheep each. Level.
Do they show any difference in the level? Not from year to year; we have had them for fourteen years.
It seems a permanent level? Yes.
Is there any apparent current in the well? I have not had that experience. Windmills.
Could windmills be availed of? We have not sufficient wind here—it is not regular enough.
President.] Did you ever know the waters of the Lachlan and the Darling to meet? I did not know them to meet right through, but I know the Lachlan and the Darling went within about 10 or 15 miles of each other, 90 miles south of Wilcannia, and there was nothing to hinder the one from joining the other. Darling and Lachlan waters joining.
What do you think is the evaporation from these large sheets of water in the shape of lakes that you have made? From 18 inches to 2 feet per year, with stock-drinking and evaporation. Evaporation.
The channel of the Lachlan is lost in the reed-beds 7 miles north of its junction with the Murrumbidgee. It then spreads over flat country, having watercourses running north, north-west, south, south-west, and south-east. The watercourses running north extend about 12 miles into the Box Creek, filling Bunoombert Lake, 28 feet deep, in passing; the water extends by channels west to Mount Emu, where it fills a lake about 10 feet deep; it then extends south to Tori Lake, which is situate 14 miles below the junction of the Lachlan and 5 miles north of the Murrumbidgee. In time of high flood Murrumbidgee waters join here; the waters then run west and north-west by several channels, a distance of 30 miles, to the Box Creek, filling several extensive lakes; the flood-waters have a spread of 10 miles wide in some places. The Lachlan water running south-east from the reed-beds flows into the Murrumbidgee, 7 miles above the junction of the Lachlan River. It also flows into the Murrumbidgee by numerous channels for 14 miles below the junction; by this it is seen that the junction of the Lachlan is 28 miles wide. Channels. Junction of Lachlan.
Within 1 mile of reed-beds all around, fresh water was obtained at 20 to 30 feet deep, which rises and falls with the flood-waters. All wells sunk north and west any distance within 40 miles of the reed-beds, having a depth of 150 feet, contain a large supply of salt water; we then meet sand-hills having a fall towards the Darling River; fresh water from this to the Darling in wells 150 feet deep. Fresh water.
There is a watercourse that leaves the Lachlan on the south side 30 miles below Booligal, runs into the Murrumbidgee 5 miles below Maude, filling three or four small lakes in its course. This watercourse at its narrowest part in time of flood is 200 yards wide and 3 feet deep. I may mention this is the only water from the Lachlan to the Murrumbidgee between the junction and Forbes. Water course.
With respect to the cuttings made on Juanbung and Tupra Runs, several of them have been completed twenty-one years; the deepest cutting has a fence either side. The silting up of this cutting is only effected by rainfall, causing a few gutters inside of bank, the deposit making bars of a few cartloads of stuff; this we clean out with long-handled shovels once a year. The shallow cuttings of 4 or 5 feet deep are not fenced, and stock are allowed to water all along, and cross backwards and forwards, thereby causing a silting up from traffic; this I remedy by taking out one ploughing every three years. My estimate for keeping all these cuttings in repair is £10 per annum per mile; none of these cuttings are damaged in the least by the passage of water. Cuttings. Silting. Stock watering. Cleaning.
Walgiers Lake, situate 20 miles below Booligal, to 20 miles above Hillston on the north bank of the Lachlan River, five main watercourses leave the Lachlan River, running in a north-westerly direction, spread and continue to Mally, 90 miles distant east of the Darling River; the higher branch (Willandra) goes through a flat country, and joins the Tallywalka about 90 miles below Wilcannia and 30 miles east of the Darling River, both waters meeting and spreading into box lakes; Watercourses.

all the other waters tend towards the Box Creek, and keep 20 to 40 miles out from the Lachlan and Murrumbidgee Rivers, and enter the Murray about Euston, there being a general network of creeks filling box swamps in passing. All the lakes on both sides of the Murrumbidgee and Lachlan Rivers are of an oblong shape, extending north to south, with high banks on the east and low banks on the west; the inlets are north or south, outlets north, south, or west. There is only one outlet on the north bank of the Murrumbidgee that carries the water to the Lachlan; that is about 20 or 30 miles

The Mirool. below Narrandera, a flat flooded country extending to the Mirool; the Mirool joins the Lachlan water that leaves the river 25 miles below Hillston, running through Gunbar Run, filling numerous box lakes, keeping out about 25 miles from the river, goes into the Lachlan 15 miles below Booligal; I have seen this creek run frequently. On the south bank of the

Watercourses. Murrumbidgee there are numerous watercourses, extending from 15 miles below Hay to Balranald, running across to the Edward 10 miles below Moulamein; the principal of these watercourses run on to Tooginbie and Nap Nap Runs; there is a watercourse leaving the Billybong 10 miles below Wanganella that runs into a lake 2 miles in diameter, holding 8 feet of water, situated 25 miles north of Moulamein; the water then runs south and west, joining the Murrumbidgee waters, and emptying into the Edward 10 miles below Moulamein. Below Deniliquin, on the Edward, 5 miles on the north and 10 miles on the south, there is a continuation of outlets running north-west and south-west, joining the Billabong and Murray waters within about 50 miles below Deniliquin, the flow on the north being very light, while on the south very

Outlets. heavy, many creeks being swimmable for a horse. The principal outlet of the Murray on the north is the Edward above Moama: then again 20 miles below Moama to the Loddon Junction, there is a network of flooded country with deep creeks extending from the Murray to Moulamein. By drawing a line from the junction of the Lachlan to 10 miles below Moulamein, and a line from Moulamein to the junction of the Loddon, you pass through flooded country the whole way. The waters of

Flood-waters. the four rivers, Murray, Murrumbidgee, Edward, and Lachlan, in time of high flood, meet in the Wakool, 20 miles below Moulamein, with a system of dams and weirs. All the surplus water in these four rivers can be utilized for irrigation, owing to the vast area the water can be made to spread over, the general character of the country being flat, having

Bed of Murrumbidgee. natural waterfalls. I have seen the bed of the Murrumbidgee dry in places from 200 yards to a mile of a stretch, about 1855 or 1856, from 80 miles above Hay to the junction of the Lachlan. I was four weeks travelling that distance, camping

Bars. and spelling a mob of horses, crossing the river backwards and forwards every day. There are sandstone bars in the bed of the river, I should say from 3 to 10 miles apart that distance; when dry they will carry a dray over like a metal road. I believe the sandstone in this river is identical with that in the bed of Bungary Lake, Tupra Run; this I quarried for 2 feet, but did not bottom. Between Echuca and Swan Hill, on the south side, the watercourses leading from the Murray do not go out a greater distance than 15 miles, then return to the river. Two rivers, Campaspe and Loddon,

Fall of country. enter the Murray between these places; the general fall of the country on the south side of the Murray is north. The character of the Lachlan and Murray Rivers is similar, the fall from both rivers being north-west—watercourses extending for hundreds of miles, while on the south of both rivers the water does not extend back more than 15 miles; add to this, several rivers feed the Murray on the south, while there are some running into it on the north. I look upon

The Murrumbidgee. the Murrumbidgee as being on a high table-land between the two rivers, having a fall both ways. The flats on either side

Irrigation. of the Murrumbidgee, say 592,000 acres, can be irrigated at a cost of £59,200 without any weirs between Balranald and Hay, by taking half the surplus water that flows to waste every year, still leaving the river navigable in all floods.

Statement of Mr. J. E. Pearce:—

As those gentlemen who have given evidence before you simply give their opinions, and having had fifteen years' experience in this district, I make bold to submit my thoughts on the subject of conserving water for the purposes of

Irrigation by steam power. irrigation. Allow me then to state, from inquiries I have made of persons who have raised water by steam-power, they have invariably told me the profit did not pay the cost. This was especially the case with Mr. Wm. M'Gaw, of Kooba Station, who tried the experiment under most favourable circumstances, having a high point of red loamy ground, on which his engine was placed, giving a slight decline for the water to flow for half a mile at least on either side. Major channels were made first by plough and shovel, then minor plough furrows carried the water over a surface of 400 to 500 acres; he had a stationary engine of about 18-horse power, and the height of lift would be from 20 to 24 feet, while everything was done as economically as possible, yet, whether the gain was equal to the cost did not concern him, his object being more to make certain a crop of hay, and to afford a certain amount of pasture for stud sheep and cows, but he assured me he did it all at a great loss. I do not say that this applies to water raised for garden cultivation on small areas and chosen spots, where, by windmills and horse-power combined, vegetables and fruit are produced. I have therefore come to the conclusion that to irrigate on a large scale so as to make the produce pay for the cost can only be accomplished by natural gravitation, and wherever mountain streams can be diverted in prepared channels and sent at various points over the land, the highest results must follow. Judging from the quantity of water that yearly runs to waste, both in the Murray and Murrumbidgee, I imagine an

Irrigation by gravitation. abundant supply could be obtained to irrigate by gravitation, and yet to leave a constantly running stream in both rivers; but the embankments required for the reservoirs would be immensely costly, and should they break away would sweep away a town situated as Wagga is on the Murrumbidgee; there is therefore great danger attending the construction of large

Reservoirs. reservoirs in deep valleys situated above towns on the same watercourse. But, supposing the danger could be overcome, in times of great floods the whole volume of water must be allowed to escape until sufficient only remained to fill the

Distribution. reservoirs to the requisite holding capacity. Again, supposing the reservoirs made with gates to allow flood-waters in their first rush to pass, the water from these reservoirs must be conveyed in surface canals for redistribution on the lower lands, and these canals would have to be flumed over creeks, billabongs, and low places, the cost of which would be very great, and yet I do not see how otherwise you can water these plains by gravitation. I am aware, when once done, the irrigated

Enhanced value. land would be enhanced twentyfold in value, but the area would be comparatively small to bear the expense, owing to the flat character of the country and its absorbing nature. To determine this question would require the most accurate survey and the highest scientific skill, and unless the land on either side of the canal were resumed would only add to the wealth of present proprietors. I should be sorry to discourage a project of this kind if the difficulties attending it could be surmounted, but we are bound to look them fairly in the face, and they are of no ordinary kind. The conclusion I come to is that irrigation to be generally profitable must be by natural gravitation, and the circumstances I fear will have to be more favourable than are found to exist on the Murrumbidgee. I have no doubt as to the practicability of damming

Locking of Murrumbidgee. or locking the Murrumbidgee, since its bed is mostly a very stiff tenacious clay, but the effects of damming in heavy floods would so impede the natural course of the water as to cut new channels, and other disastrous effects might follow. I think locking a much preferable plan, as it would throw the water out in various billabongs where needed, and offer less

The Murray. obstruction in times of flood, as well as keep the waters at a better height for those who desired to irrigate artificially. I believe my conclusions, as regards the waters of the Murrumbidgee, will apply to those of the Murray, only in that case Victoria would have to be a consenting party, and one-half of the water flow would be claimed by her. I wish

The Lachlan. further to state that scarcity of timber for fuel will always operate most seriously against the use of steam for lifting water for irrigation throughout the whole of this district. The case of the Lachlan River is very different to that of the Murrumbidgee or the Murray. The catchment of the Lachlan is not so large as either of the other rivers; and while in the Upper Lachlan the bed is a deep wide ravine, capable of conveying a great volume of water, as it gets into the low flat level country there are numerous creeks and billabongs that divert the streams, which are nearly if not quite as large as the river becomes after they branch away from it. I refer first to the Willandra Creek, which, when in full flood, is nearly if not quite equal to the Lachlan. After it leaves that creek, then the Merrowie Creek takes off a third more, and then the Tooroogannie Creek takes another share of the Lachlan waters, besides numerous billabongs which break out of the Lachlan and flow on, some for hundreds of miles—in fact, there is no water to spare out of the Lachlan when all these creeks and ana-branches are supplied, and the chief thing needed is that these creeks as well as the Lachlan should all be

Dams. dammed continuously with low constructed dams throughout their whole course. This can be easily done if the dams are made in the creeks or rivers at the mouths of the billabongs just high enough to divert the water into the billabongs, which will then flow round to the back of the dam, and not wash it away when the water rises over it. There ought to

Trusts. be a local Trust appointed to regulate the place where, and the height, these dams should be constructed; of course they

Wells. might be overlooked and carried out under the inspection of a practical engineer. Respecting wells, there are large tracts of country where fresh or good stock water can be obtained at from 80 to 100 feet; this is chiefly so on the south side of the Murrumbidgee, but to the north, as you go towards Mossgiel, Clare, and numerous other stations, it is very difficult to strike upon good stock water, and in such country an artesian bore might be of great value.

Reservoirs. P.S.—In reference to the Lachlan River, I ought to have observed that the construction of reservoirs anywhere on its branches at its head, to store water to keep up the gradual waste by evaporation and absorption on the lower part of the river, its creeks and billabongs, would be of immense advantage.

APPENDICES TO THE EVIDENCE

TAKEN BEFORE THE

COMMISSIONERS.

For Maps, Plans, and Diagrams referred to in the Evidence as Appendices, see the accompanying Portfolio.

ROYAL COMMISSION ON CONSERVATION OF WATER, &c.

APPENDICES.

[*Documents forwarded by Mr. David Greig, and ordered by the Commission to be printed*, 21 *August*, 1884.]

Mr. Goyder to Mr. D. Greig.

South Australia, Surveyor General's Office, Adelaide, 11 August, 1884.

CERTIFIED that the agricultural machinery and implements, comprising traction and drawing engines, fuel and water-tank-engines, steam-scoops, cultivators, ditchers and drainers, to the value of over £22,000, ordered by me for the Government of South Australia, of Messrs. Fowler & Co., of Leeds, were constructed and completed in the most careful manner, and manufactured of the very best material.

Since their arrival in this province they have been worked to my entire satisfaction, and I have much pleasure in giving this certificate.

G. W. GOYDER,
Surveyor-General.

ABSTRACT of what has been done by the Steam Scoops imported by me for the Paratoo Station—one set in 1877 and one set in 1881.

	£	s.	d.
Two sets engines and scoops, including duty, preliminary expenses, two scoops put aside, railway charges, cartage, &c., and wear and tear on bullock drays, &c., in attendance...	7,907	15	3
Amount paid for wages and management	5,233	16	8
Cost of rations	1,159	2	1
	£14,300	14	0
Less present value of imported plant—say	6,000	0	0
	£8,300	14	0

Something like twelve months was taken in the first instance before we got the tackle fairly to work.

Work completed to 31 Dec., 1883,—289,349 cubic yards, for which I estimate the value to the station ... £14,974 5 4

Of this 147,726 yards were taken out below the depth of 10 to 26 ft., or say a cost of 6¾d. per yard.

The saving in cost by no means represents all the benefit my runs have derived from the scoops. The greater depth, unattainable by bullocks, has enabled me in dry seasons to keep sheep in paddocks from which they must have been moved months before rain came, had I only had bullock scoops.

Adelaide, 11 August, 1884.

THOS. ELDER.

Mr. P. Waite to Mr. Greig.

Dear Greig, Adelaide, 11 August, 1884.

I have much pleasure in giving you an abstract of what the steam scoops have done for us, and at the same time to thank you for the great trouble you have taken in bringing them to their present state of perfection. I have no hesitation in stating that without them much of the country we are now successfully occupying could not have been occupied at all.

We have sunk wells without result until we are fairly sickened of well-sinking, and we are now making the country permanent by tanks of 18 feet to 26 feet, of the following dimensions: 80 yards × 60 yards, 80 yards × 70 yards, and 80 yards × 80 yards; the latter two are what we usually make them, and you must bear this in mind when you compare costs. You will find as a rule the widest tanks made by private individuals do not exceed 50 yards; and as the cost of excavating is materially increased by the distance the dirt has to be carried, you must allow a fair margin in comparing the cost of excavating the 50 yards and the 80 yards wide. You will also have to take into consideration that the bulk of the work done by the steam scoops was from 10 feet to 26 feet, and not from 1 to 26 feet.

We keep a large force of bullocks with the ordinary bullock scoops taking the top off, not because they can do it cheaper, but by carrying on in this way, we get so many more deep tanks made in a year than if we kept the engines completing the job from the beginning. I fully expected having six scoops at work, and would have had them had we not had the energy knocked out of us by bad legislation.

The machine itself is as nearly perfect as possible,—all that is wanted is a man with a little common sense to manage; not an engineer, but a good sensible blacksmith like what we have. There is nothing about the whole affair but what a man of ordinary ability can grasp in a day or two.

Yours very truly,
PETER WAITE.

Mr. H. B. Hughes to Messrs. John Fowler & Co.

Adelaide, 11 August, 1884.

I RECEIVED your letter of 4 July, and have had the pleasure of meeting your senior practical partner, Mr. David Greig; and in reply to his questions as to how the engines and scoop have succeeded in charge of my men, I can say that men require experience in order to work efficiently and economically. My first tank—contents 23,740 cubic yards—I reckon cost 1/10¾ per yard, which includes charges for repairs, also 20% per annum for interest and wear and tear; depth, 21 feet. The second tank, 17,787 yards, cost £533 9s. 1d., or 7¼d., depth 14 feet; the third tank, 18,857 yards, cost 8½d., £676 9s. 10d.; the fourth tank, 8,068 yards, cost 8¼d., £279 11s. 3d., depth 17 feet; the fifth tank is now being made. The engines and scoop arrived at Menindie Station, October, 1881. I refer you to enclosed statement of cost of 8,068 cubic yards, or the latest work completed.

Yours truly,
HERBERT B. HUGHES.

STATEMENT of cost of excavation made by engines and scoop of Messrs. John Fowler & Co.'s make, at the East Balaklava Tank, Menindie Run, New South Wales:—

1884.	£	s.	d.
February—To wages	28	3	8
March— ,, ...	68	10	11
April— ,, ...	43	0	0
,, To kerosene, &c....	1	12	0
February—To rations	10	13	6
March— ,, ...	12	12	10
April— ,, ...	12	14	4
To interest 10%, wear and tear 10%, on cost of plant £3,365 12s. 11d. for two months	112	4	0
	£279	11	3

8,068 cubic yards excavated, at 8¼d. = £279 11s. 3d.
5,203¼ cubic yards had been previously taken out by bullocks.

13,271¼

Kinchega, 9 May, 1884.

H. T. PHILLIPS, Manager.

The above tank is 101 yards long × 42 yards wide and 17 feet depth.—H. T. PHILLIPS.

Mr. A. H. Doudney to Messrs. John Fowler & Co.

Dear Sirs, Steam Scoop Camp, Government Tank Works, Babinda *via* Nyngan, 2 August, 1884.

You will be pleased to hear I arrived here safely with the plant twelve days ago, and that we have made considerable progress in the work here.

We have had to do an immense amount of clearing so as to make room for the engines to work, and it is chiefly on this point I am addressing you.

I think you should be made aware of the wonderful faculty your engines possess for clearing land. In three days, with one engine, I rooted up and dragged away very nearly 400 trees, varying in size from saplings to trees 2 ft. 6 in., and 3 ft. through.

In the 15 acres of clearing, I never had so much as to even ease the roots, and the people who witnessed the performance declared it marvellous.

I have pulled as many as fifteen trees down without shifting the rope, by means of the bight of the rope. We would run the rope out, making a half circle, and fasten the end of the rope to the butt of a tree. Then as the strain came on, the bight of the rope would (by means of forks) be shoved pretty high up the tree, on which the strain would come, and over would go that tree. The engine would wind in again, and as the rope tightened it would be forked up the next tree, on which the strain of the bight would come. And so on, until all the trees would be down, excepting the one on which the rope is made fast; the rope would be forked up on this one, and she would then come.

Chain slings are a mistake—the slightest jar and the links snap. I simply put the rope round the tree, and shackle on to the standing part. The larger the tree, as a rule, the easier it comes, the head of the tree being of great assistance.

With one 16-horse power, a van truck (for the camp), a water-cart and two horses, three men and a driver, an energetic man could make a fortune, taking contracts for clearing bush roads. In this direction there is a great opening, as against the old style of grubbing and burning off.

I am, &c.,

A. H. DOUDNEY.

Mr. A. H. Doudney to Messrs. Fowler & Co.

Dear Sirs, Steam Scoop Camp, Babinda, *via* Nyngan, 6 August, 1884.

Yours of the 4th instant duly to hand, and contents noted.

We are still continuing to show great progress, and there is more stir and excitement about the plant amongst the district and passers-by than I have ever before observed.

You will be pleased to hear that, following your Mr. Greig's advice—re-fixing up the worn guide-blocks,—I have got the coiling gear on both engines to work A 1.

The new scoop is upon the point of starting from Sydney for here. I have had oil-cups fixed on the wheels, in the place of the old style of oil-holes and wooden plugs. The flow of oil I have regulated by means of a leaden bullet inside the oil-cup. When the cup comes up, the bullet falls over the vent and blocks the oil; she therefore lubricates only whilst the cup is horizontal. It is just an idea of mine, and I hope it will answer. The wooden plug style is bad. Every time the plug is taken out dirt falls in, and much time is lost in the frequent oilings.

I have been looking over the particulars of new scoop, and am highly pleased. I note the axle arms are much larger in diameter and 3 inches longer; this I attach great importance to, because it is impossible always to avoid pulling the scoop a little sideways, and that is the time when the axle arms feel the strain. I do not believe in the bell mouth; a straight scoop (with mould boards on the wheels to prevent their running over the ploughing and keeping the mouth up) would fill better, easier, and take more dirt by far, and there would be infinite less clogging of damp earth. This is Bisset's idea, and the more I study the matter the more convinced I feel that Bisset's view is right.

I am, &c.,

A. H. DOUDNEY.

Mr. J. W. Jones to Mr. Greig.

Sir, South Australia, Department of Water Conservation, Adelaide, 11 August, 1884.

Your visit to Adelaide gives me a fitting opportunity of saying that the six sets of steam scooping machinery supplied by your firm to the Government of this Colony have, after a trial of a year and a half, been found to be of very high-class workmanship and quality, reflecting much credit upon your establishment.

The traction engines have been found fully capable of hauling the entire set of machinery, camp equipage, &c., &c., over the natural roads in the interior to the various sites of operations in reservoir excavating, in most cases from 50 to 100 miles from the railway.

The engines have been worked entirely with the native wood of the locality, and in many cases under great difficulties, with very brackish water, often as salt as the sea. This has, however, necessitated very frequent washing out, and should be avoided as much as possible.

In ordinary work the engines and other appliances are strong enough, but occasionally very unusual strain has caused the breakage of the brackets, and the upright shaft and some minor parts, which I have already pointed out to you That is very easily remedied, and indeed might never have occurred with more experienced men.

As to the actual results of scooping, and this is, of course, the main point I have to consider, I am now in a position to judge with some authority, for several reservoirs have been completed to 20 feet deep, with a capacity of about 25,000 yards each, the slopes being 3 to 1, and the bulk of spoil removed 150 feet, to form embankment 10 feet high.

The cost of first reservoir was, including wages, transport, supply fuel, forage, stores, &c., &c, 1s. 1½d. per cubic yard. Some others have cost about the same, and in one or two cases where the difficulties of transport of machinery and supplies—60 miles, and cartage of fuel and water, 10 to 15 miles—the cost has been greater. It must be remembered, however, that every man employed with the machinery has had to be educated to the work, and this has been a matter of much difficulty. In future the danger of accidents should be much lessened, and the cost of excavating materially reduced.

It is a very great point in favour of the machinery that the depth is no difficulty; from 20 feet to 30 feet may be attained as easily as 10 feet. and our results have shown us that this can be done at the same price as the first 10 feet. This is of the utmost importance in these works, as previous to the introduction of the machinery the reservoirs and dams seldom exceeded 12 feet deep, in consequence of the difficulty in getting contractors to go deeper, and also the very much increased rate for every foot deeper, and as the evaporation is from 60 to 80 inches per annum, the importance and value of deep sinking, to prevent evaporation, can be adily estimated.

The contract rates to 15 feet deep have, in out-lying places, ranged as high as 2s. 6d. to 3s. per cubic yard. With the experience the men have now had in working the machinery, and when some necessary alterations are made to the scoop, I am fully satisfied that much better progress will be made, and the cost per cubic yard materially reduced, and that the machinery will give very general satisfaction.

I have, &c.,

JAMES W. JONES,

Conservator of Water.

[*Ordered*

[*Ordered by the Commission to be printed*, 28 *August*, 1884.]

Mr. D. Greig to The Secretary, Royal Commission on Conservation of Water.

Sir, 43, York-street, Wynyard Square, Sydney, 21 August, 1884.

Having just returned from seeing six sets of our steam scooping-tackles at work in South Australia, I am in a much better position to speak on the question of my scoop excavating machinery than I was when examined before the Commission on 1st July.

I have been very agreeably surprised to find the machinery much more perfect in its detail than I expected to find it. The six machines I saw were working with the greatest regularity and doing the work in the most satisfactory manner. I have tried to get as much information as possible as to expense, &c., and I have forwarded to you the result in a pamphlet, twelve copies of which have been left at your office.

It is quite clear that in the starting of these machines the want of knowledge has added most materially to the expenditure, and has been the only drawback. The question of men is not now got over, as they are continually educating new hands, and I have no hesitation in saying that the amount of work done per day is more than doubled, and with certain improvements, which I see my way to make, we shall be able to take out a much larger quantity of dirt at the same expense. So far as I see, I apprehend no difficulty in taking out the earth at 6d. per cubic yard.

The slopes of the tanks and of the embankments were very nearly mathematically correct, and no one could see them without being pleased with their regularity.

Begging to be excused for thus trespassing on your time,—

I am, &c.,
DAVID GREIG.

APPENDIX A 1.

LIST of the River Gauge readings received from the Harbours and Rivers Department.

Murrumbidgee Improvements.

- Gundagai .....August 1st, 1876, to March 31st, 1877; May 1st, 1877, to December 31st, 1877; May 1st, 1880, to February 28th, 1881.
- Wagga Wagga...August 1st to 31st, 1876; October 1st, 1876, to March 31st, 1877; May 1st to October 31st, 1877; May 1st, 1880, to February 28th, 1881.
- Narandera .....August 1st, 1876, to January 31st, 1877; March 1st to 31st, 1877; May 1st to November 30th, 1877; May 1st, 1880, to February 28th, 1881.
- Hay.....Weekly observations during August, September, October, 1876. Daily observations began November 1st, 1876, to February 28th, 1881.

Murray River.

- Tide gauges at Wahgunyah, Echucha, and Swan Hill. Observations taken weekly with barometer, thermometer, and remarks. January 6th, 1869, to February 24th, 1869; April 14th, 1869, to June 26th, 1872. Daily observations of water gauge, and time taken by a float to pass over 300 yards.
- Swan Hill.....August 1st to December 31st, 1872; January 1st to 31st, 1873.
- Euston ..... August 18th, 1872, to May 31st, 1874; July 1st, 1874, to December 31st, 1874; January 1st, 1877, to May 31st, 1878; July 1st, 1878, to April 30th, 1879.
- Custom-house ...October 1st to 31st, 1872; December 1st to 31st, 1872.
- Albury .....January 1st to September 30th, 1873; November 1st to December 31st, 1873; January 1st to February 28th, 1874.
- Tocumwall.....September 1st, 1872, to September 30th, 1873; November 1st, 1873, to May 31st, 1874; July 1st, 1874, to November 30th, 1874.
- Corowa .....August 12th to 31st, 1872; October 1st to 31st, 1872; January 1st to 31st, 1873.
- Mildura Gauge...Weekly readings, October 10th, 1869, to August 28th, 1870.

Darling River.

- Albemarle.....Daily observations of the height of the Darling River, May 7th to August 24th, 1870; September 1st, 1871, to April 19th, 1872; April 27th, 1872, to May 24th, 1872; June 1st to July 12th, 1872; July 26th to August 31st, 1872. Table of errors.
- Wentworth .....Daily observations, September 1st, 1872, to September 30th, 1873; November 1st, 1873, to April 30th, 1874; August 1st, 1874, to December 31st, 1874; December 1st, 1876, to August 31st, 1877; October 1st, 1877, to June 30th, 1879; August 1st, 1879, to October 31st, 1880; and December 1st, 1880, to February 28th, 1881. Some broken observations, no year mentioned, but fastened to the Albemarle returns of 1870. September 12th to November 11th; April 7th to August 22nd.
- Bourke .....Daily observations. September 1st to October 31st, 1872; December 1st to 31st, 1872; February 1st to September 30th, 1873; November 1st to December 31st, 1873; January 1st to March 31st, 1874; May 1st to 31st, 1874; and August 1st to 31st, 1874.
- Extracts from Darling River gauge reports, from September 1st, 1871, to July 26th, 1872. Look like monthly means.

Sydney Observatory, July, 1884.

APPENDIX A 2.

TABULAR Statement showing the Mean Height above Summer Level of the River Murray for each Month of the Year, at Moama, from July, 1863, to December, 1883, inclusive.

Prepared by C. E. Gordon, Esq., H.M. Customs, Moama, 1863 to 1878.

APPENDIX A 6.

P. H. Gell, Esq., to H. C. Russell, Esq.

Dear Sir, Overton, Urana, 27 February, 1882.

As you say in yours of January 31 that you will be glad to receive any memo. I may have as to our rivers, I send under separate cover two diagrams illustrating the flow of the Murray River for portions of thirteen years. The first is from observations made at Lake Victoria, near the boundary of South Australia, and of course below the junction of the Darling; the second made at Ki, near Euston, 60 miles above the junction of the Darling. The first is merely a record of the height of the river for part of the years 1863-4-6-7, and 8; the second shows an attempt made to ascertain not only the height, but the discharge of water in cubic feet per second, for part of the years 1870-71-72-73-74-75, and 76.* At the latter place I was kindly assisted by Mr. A. Woods, of the Harbours and Rivers Department, in making those cross-sections of the river-bed and also the ana-branches and flooded country opposite the station. I also had an accurately measured distance on the banks in order to observe the velocity of the current. I need not trouble you with an account of the various experiments tried to obtain the mean velocity. These have been reduced to a formula which I found to be this, nearly: "the maximum velocity multiplied by ·85 equals the mean velocity." The time taken by a float to pass the measured distance is given on the diagram. This column is a mean result of at least a hundred observations, but is only approximately correct, as the velocity varies so much with a high or low, a rising or a falling river. My calculations made some time ago, were made with the actual observed mean velocity at the time. There is also a column of the area of water-way at each foot in height, but I used the computed area for every inch in making the calculations. Of course this attempt made by an untrained observer to obtain some idea of the quantity of water discharged by the Murray is not what one could wish; but so far as I am aware nothing of the sort has been previously attempted, and there may come a time when these early notes may have some value as a record. When I sold Ki the new proprietor did not reside, and his manager was not competent to keep the record, which I regret, as so grand a rain gauge deserves a record. There are some memos. on the first plan showing when came the water causing the rise. These will, by a comparison with the rain records, show how different circumstances alter the time taken by rain to reach the lower river. As a general rule the higher the river the quicker the wave travels. This from several causes, that are not of equal power. With a low river the obstructions are greater, also the distance, and the level reaches to be filled more numerous. With a high river, the surface on which the wave travels is itself moving quicker. It is a matter of some importance to steamers, as navigable freshes have travelled down the Darling so slowly as to leave the upper river unnavigable before the boats could leave the Murray water. Local rains do not affect the height of the river in an appreciable degree. I observe a remark in your book on the Climate of New South Wales, with regard to the Murray, that you will permit me to notice. You say, page 8, that the Murray finds the ocean at Port Elliot in South Australia. Port Elliot is an open bay several (I think 7) miles from the Murray, which river finds the ocean at a place called the Murray Mouth, an opening in a sand-bank near Port Goolwa—a sand-bank that partially separates the water of Lake Alexandrina, through which the Murray flows, from the ocean. River steamers have many times steamed over the bar at the Murray Mouth, but the passage is dangerous and the river boats are altogether unsuitable for such navigation, and, in my opinion, any attempt to improve the channel would either be useless or involve a vast expenditure. After an inspection of the various proposed modes to connect the Murray and Darling with the sea, I, eighteen years ago, wrote a report published in the Adelaide papers, advocating the proposal to make a railway from Goolwa in Lake Alexandrina, to Port Victor on the coast, and works there to connect Granite Island with the mainland. These works are now slowly approaching completion. The Government in the meantime have spent a large sum of money in making a railway from Adelaide to Morgan, on the Murray, as a sop to the Adelaide property-holders. Although I have now been for so many years an interested and attentive observer of the navigation of the Murray, I have always thought that cheap railways would in a great measure supersede this risky and uncertain mode of transport, in spite of its cheapness. No doubt the river steamers have been of essential service in developing the interior, but it is in connection with irrigation, not navigation, that our rivers are of superlative interest in this dry country; and when I note the ease with which the Murray lends itself to works of irrigation I am astonished at the persevering though unorganized and ill-directed attempts to discover underground sources of water supply, whilst tons upon tons of water, easily available, are rolling uselessly into the sea every year. Your interest in the notes already sent encourage me to make some further remarks on the Murray River, as I know it from the mountains to the sea. For 100 miles above Albury the Murray River has the ordinary character of a mountain river, with a rapid current, in a rocky bed, in a comparatively narrow valley; the flooded ground is limited but rich, the hills poor and steep, the scenery picturesque. Below Albury the flooded country, intersected with ana-branches, shows its increased capacity, whilst the current is much slower, the total fall from Albury for the next 600 miles to the Murrumbidgee junction being only 320 feet. The head of the navigation may now be considered to be at Corowa; as far as I know, only two steamers have made Albury during the past five years. This is because there are railway facilities on the Victorian side above Corowa. Flooded gum and wattle trees are found along the banks to the junction of the Campaspe, about 325 miles by river from Albury; below that no more wattle is seen, and about 100 miles further the banks get lower, the level ground on either side opens out, and at Swan Hill, 500 miles from Albury, an enormous area of flat flooded country without timber extends on both sides. This was no doubt once a vast reed-bed or swampy lake, the feeding and treading of stock having now nearly destroyed the reeds; here the river in the high flood of 1870 only rose 13 feet above summer level: at the same time it rose 25 feet 100 miles lower down. The lip of the Swan Hill basin forms an obstruction in the river much dreaded by steamers, called the Bitch and Pups; and below it flooded box and gum line the banks, the flooded country being 5 or 6 miles wide, the river channel being sometimes on the north, sometimes on the south side; as it runs to the west, numerous ana-branches, locally called creeks, intersect the flooded country. The dry plains may be about 20 or 30 feet above the flooded country, but these plains are also intersected by ana-branches that carry water in such floods as 1870. The Wakool and Edwards, called rivers, can only be considered ana-branches, and join both the Murray and Murrumbidgee in high floods. 20 miles above Wentworth, at Mildura Station, is the only place where a bridge of moderate length would cross the water. Here both banks are high, and it is the best place I know for keeping a record of the discharge, as the whole of the water in flood-time is in sight of the station. Below Mildura the sandstone rock appears at low-water—a stratum of rock that seems to lie with great uniformity. For 150 miles more west, that is 80 miles west of Wentworth, this rock appears on the banks, and at Blanch Town, in South Australia, 1,300 miles from Albury, the river has cut through this rock so that it forms high cliffs on each bank. Below Blanch Town the flooded box ceases, and for 90 miles to the sea the river has more the character of an estuary of the sea, although quite fresh; indeed, the fresh water can often be traced quite through Lake Alexandrina—30 miles—although the lake is salt. The outlet to the sea is through a sand-bank of much the same character as the entrance to the Gippsland Lakes, and would soon be closed if the water brought down by the Murray did not keep it open. 15 miles above the boundary of New South Wales, Lake Victoria forms a large receiver of about 30 square miles, into which the flood pours for many months, to pour out during January, February, and March, by the Rufus Creek, mistaken by Sturt for a river running in from the north. You may ask do I think our rivers carry off our rainfall? So far as I know there are no data for a satisfactory answer, but my opinion is that increasingly they do. The treading of stock, and the consolidation of the surface, causes more water to reach the rivers than formerly, hence we may expect higher floods, and less low water. Sturt describes 90 miles of the Darling as salt. I have not heard of that since. I saw the Murray so low in 1866 that I drove over it in a buggy at Wentworth below the junction of the Darling. Mr. Corzier told me that he had seen it much lower, being then a mere chain of salt pools, with a run of fresh water from pool to pool. The ana-branch of the Darling, which now in high floods forms a supplementary channel joining the Darling to the Murray, had never in the memory of the oldest blacks been known to run through to the Murray water until the flood of 1864. The quantity of water it carried in 1864 will be seen by reference to my plan No. 1 in June and July, noting that at the gauge the Murray at that time was at least 7 miles wide, and very rapid. For the ten years before 1864, there had been a very great increase of stock on the Darling. No such flood in the Murray as 1870 could have happened for fifty years, as I could show.

I have said that the Murray lends itself to irrigation works, because I am credibly informed that a saddle which I have been over, but not examined, exists a few miles above Albury, where a channel could easily be brought from a low overshot dam in the Murray, so as to emerge from the Murray valley, without tunnelling or other expensive work. Once on the plains, the matter is only a question of time. It must also be remembered that the Murray is fed by snow-water from the mountains, and is not dependent on the irregular rainfall of the plains, or like the Darling, the uncertain extension south of the tropical rains. Thus we may make sure of a spring flood just at the time when the water is most wanted, and if

* The tabular statement only goes to Aug. 12, 1874. 1875 and 1876 will be found on the diagram.

if only the spring flood could be sent into the plains, who can say how much it might modify our Riverine climate. Now, looking at the enormous area of flat country below the level of the Murray at Albury, it is quite evident that there is not nearly enough water to irrigate half the land under the level of a gravitation channel, but one-fifth of the discharge would irrigate a million acres, and at 10s. per acre per annum (the lowest charge made anywhere), would give an annual income of £500,000.

Do I think that anything will be done in this matter? Certainly not; we live under the worst possible form of Government to carry out such works, even if our Ministers were superhuman. Fickleness, jealousy, ignorance, selfishness, are all against it. We have men who are willing to give liberally to our public institutions, but where is the man with the knowledge, the time, the money to carry out such a work, even with public funds? We want men like Sir Thomas Middleton, who made the New Cut, or the Duke of Bridgewater, but I am afraid our newspaper politicians would kill them.

The craze for individual liberty is adverse to any large combination, such as this undertaking would require—hence the persistent well-sinking, so poor, but under our circumstances, the best possible substitute. The squatters are particularly unable to combine; they are so used to be cocks on their own dunghills that they can't work together, and besides, the Land Law, whilst it induces them to put on bogus improvements as to those that might be shared by the public, says no; but I am wandering beyond my intention, which was to send you a few notes about the Murray River.

And beg to remain,
Yours faithfully,
P. H. GELL.

APPENDIX D 5.

[*Extract from Reports of Board appointed to advise on the feasibility of giving a supply of water to the Northern Plains, Victoria.*]

The Wimmera Scheme.

* * * * * * *

We have availed ourselves of the best information existing as to the rainfall and the discharge of the rivers, but it is to be regretted that there is very little exact information on the latter subject. This is not of so much importance as regards this part of the inquiry, but it is absolutely necessary that more exact and complete data should be obtained before any extensive system of irrigation or large distribution of water for agricultural purposes can be considered; and we have accordingly taken steps to obtain the necessary information as to the discharge of the principal rivers in the northern division of the Colony, by establishing gauges and a system of registering the rise and fall at suitable points.

* * * * * * *

7. Before proceeding to describe in detail the works proposed, it is desirable that we should give a short description of the Wimmera River, its sources and watershed area, so as to convey an idea of its capacity as a source of supply, and that we should explain the basis of the subdivision and distribution proposed. Above Longerenong, the river may be described as consisting of two main branches, the east and the west, the former having its sources in the Pyrenees, and the latter in the Grampians, the area of the watersheds being respectively 790 and 550 square miles. Below Longerenong the river receives several tributaries from the left, viz., the Burnt Creek, the McKenzie River, Norton's Creek, and the Mia Mia Creek, having an aggregate drainage area of 520 square miles, but with these we are at present not particularly concerned, except as affording a supply to the river below the points at which the drain on its resources by the proposed scheme will terminate. Below the Mia Mia the river has no tributaries. From observations of the rainfall made at Hall's Gap, Stawell, Horsham, and Decameron (the latter kindly supplied to us by Dr. Williamson), it is estimated that the water supply from the eastern drainage area is to that from the western as 100 to 85 in average years, and as 100 to 99 in very dry years, while the supply from the tributaries below the junction of the main branches is to that of the total area above it as 27 to 100. The river ceases to flow in summer, although several of the tributaries are permanent streams near their sources, but the usual winter discharge is very considerable, and extreme floods have occurred, of which there is evidence that the discharge was enormous. In ordinary years the river may be said to terminate in Lake Hindmarsh, but the channel can be traced thence through Lake Albacutya for about 25 miles further to Pine Plains, where it finally disappears. Two or three times only in the history of the Colony has the river water been known to reach this point.

APPENDIX D 6.

Number of acres per square mile that could be irrigated in the Wimmera District, supposing that the whole of the supply could be impounded and applied to irrigation (which however is not feasible):—

The estimated discharge of the Eastern Wimmera in good average years is 8,546 million cubic feet, and of the Western Wimmera 4,754 million cubic feet; together, 13,300 million cubic feet. Allowing 10 per cent. for domestic use, &c., and 75,000 cubic feet as the quantity required per acre for mixed irrigation, exclusive of pasture, the number of acres that could be irrigated is about 160,000, or 58 per square mile of country commanded, but as some of the country would not be commanded by gravitation, probably 60 acres per square mile.

G. GORDON.

APPENDIX D 7.

AGRICULTURAL STATISTICS OF THE COLONY OF VICTORIA FOR THE YEAR ENDED 1st MARCH, 1884.

MEMORANDUM.—The following Tables relating to Irrigation are supplementary to the General Tables published in the Government Gazette of the 4th April. In the case of crops subjected to irrigation in any Shire, the extent of land not so subjected and so subjected is given in Table I; and the produce grown under each of those conditions in Table II. No figures are given respecting crops in any Shire of which no portion within such Shire was subjected to irrigation.

Office of the Government Statist, Melbourne, 22nd May, 1884.

HENRY HEYLYN HAYTER,
Government Statist.

APPENDIX D 8.

[Extract from Reports of Board appointed to advise on the feasibility of giving a supply of water to the Northern Plains, Victoria.]

THE GUNBOWER SCHEME.

18. We append a Schedule of the works in the order of their importance, with an approximate estimate of their cost, and we include in it a list of works already carried out by the Shire Council of Swan Hill, which will fall in with the scheme, and may therefore be considered a part thereof.

Schedule of Works proposed.

	£ s. d.	£ s. d.
Enlarging and deepening the inlet to the Gunbower and head works	920 0 0	
Deepening Taylor's Creek	40 0 0	
Weir below Taylor's Creek (not required till works require renewal)	750 0 0	
		1,710 0 0
Weir on the Loddon and Sheepwash Creek and improvement of channel to lakes		1,750 0 0
Head works at inlet of Deep Creek	300 0 0	
Permanent weir at Cohuna when required	1,500 0 0	
Deepening Barr Creek and enlarging bridge	200 0 0	
		2,000 0 0
Additional channels, weirs, and tanks (paragraph 15)		2,500 0 0
Macorna channel, with channels and tanks		7,570 0 0
Engineering and contingencies		1,561 0 0
Approximate cost of works already completed and in progress by Shire Council as per list appended		1,509 0 0
Total		£18,600 0 0

Of which only £7,787 would require to be expended immediately.

The total sum of £18,600 amounts to £26 19s. 1½d. per square mile, or about 10d. per acre. The annual expense would be approximately—

	£ s. d.
Interest at 5 per cent.	930 0 0
Maintenance	500 0 0
Collection of rates, &c.	200 0 0
Total	£1,630 0 0

This amounts to rather more than ¾d. per acre of the land commanded by the scheme, including the State forest.

Works already completed and in progress by Swan Hill Shire Council which, in our opinion, should be included in the expenditure on this scheme :—

	£ s. d.
1. Loddon and Sheepwash dam, compensation to Mr. Fairlie, and small dam near Lake Charm	117 16 0
2. Gunbower dam	218 11 0
3. Cohuna dam	184 8 8
4. Thomson's dam on Barr Creek (present value)	400 0 0
5. Kerang dam, supplying township...	64 18 0
6. Wandella Lake channel	133 11 3
7. Lake Elizabeth, inlet to	350 18 9
8. Garden's station dam, Barr Creek	36 2 0
Total	£1,506 5 8

Nos.

Nos. 2, 3, and 5, although they cannot be considered permanent works, are included, because they are works of great utility, and it is not intended to supersede them by more permanent works until required. At the same time it is not recommended that any great expense should be incurred in repairing or maintaining them.

APPENDIX D 14.

Report on the Navigation of the River Darling, by G. Gordon, C.E.

To the Provisional Directors of the River Darling Navigation Co.

1. I have given my careful consideration to the subject which the Board did me the honor to refer to me for my opinion, viz., the making of the river Darling permanently navigable from Wilcannia to Wentworth.

Character of the river.

2. The river for a distance of 368 miles above Wentworth has a fall of only 92 feet, or an average of 3 inches per mile. This fall is tolerably uniform, but the regularity is somewhat disturbed at low-water by the bars of rock which occur here and there. The present condition of the river is not stable; it is in a state of constant gradual change—the banks on the hollow side of the numerous bends are increasing in their convexity. This process going on for long periods of time occasions the formation of the narrow necks between reaches of river separated by miles of distance if measured along its course, and eventually the breakage through of these necks. As the process of the lengthening of the bends by this action is counteracted by the occasional breaking through of the necks, it is probable that the length of the course of the river is not materially altered, and that its *régime* may be considered generally permanent, though locally unstable.

3. In dry seasons the river, as regards navigation, practically ceases to flow, while the great floods reach the general level of the tops of the banks; and it is chiefly with regard to these two features that the mode of treatment will have to be determined.

Data.

4. By the kindness of Mr. Moriarty, Engineer-in-Chief of Harbours and Rivers, I was allowed to have tracings made of the survey of the Darling from Wentworth upwards for a distance of 386 miles. Beyond this the survey is incomplete, and the levels are wanting; but for the purposes of a preliminary report it will be sufficient, in view of the similarity of the character of the river above and below this point, to assume the fall to be practically uniform from Wilcannia to Wentworth, a distance of 500 miles. I examined the upper portion of the river, but owing to want of depth of water I could not navigate the whole distance to Wentworth; but I examined the river at different points of its course below Menindie.

Object of improvement.

5. The ends desired to be obtained in the improvement of the river are—
   1st. Permanent navigation throughout the year, both at low-water and during floods.
   2nd. The least possible heightening of the flood-level.
   3rd. The re-establishment of natural navigation—*i.e.*, without the help of locks—at as early a stage of a flood as possible.

Modes of improvement.

6. There are five principal modes of assisting the navigation of inland rivers—
   1st. By dredging the shallows.
   2nd. By contracting the channel by longitudinal banks, so as to give greater depth over the shallows.
   3rd. By floating—that is, by impounding the water by means of a system of weirs, and opening one of them suddenly so as to produce an artificial flush, on top of which a fleet of boats can be floated down to the next weir, which would then be opened; and so on.
   4th. By impounding flood-water in large reservoirs in such quantities as will, when released, maintain a navigable depth in the river throughout the dry season.
   5th. By canalization—*i.e.*, by dividing the river into a series of level ponds, of sufficient depth for navigation, by means of weirs furnished with locks for the passage of vessels.

In the case of the Darling the first and second of these methods are inapplicable, because of the very small discharge of the river during summer,—a condition which would be aggravated by these methods, as the discharge of this small quantity would be made more rapid. The third method could only be advantageously employed on certain portions of the river, because in the very long ponds between some of the weirs the artificial fresh or wave would be apt to pass down with too great a velocity. This method also involves considerable difficulty in manœuvring the weirs. The fourth cannot be entertained, as there are no sites for large reservoirs. I therefore recommend the last-mentioned plan, viz., canalization combined with the deepening of the said channel in places, so as to be navigable by vessels drawing 6 feet of water.

Kind of works recommended.

7. Without detail surveys the exact position of the weirs and locks cannot be determined, but they would probably be nearly in the positions chosen in the accompanying diagram,* advantage being taken of the cut-offs for the location of the locks (when otherwise desirable) so as to save distance for navigator and gain length for the weirs. The weirs should offer as little obstruction as possible, so that their effect on a flood should disappear as soon as may be. I have therefore fixed the lift of the locks generally at from 4 feet to 6 feet 6 inches only, both with the object just mentioned and also in order to reduce the cost of the weirs, which would increase in a greater ratio than their height; but a few have a greater lift. The locks would be submerged during high floods. When, in consequence of a fresh, the river could be maintained at such a depth as to be navigable, a navigable pass in the weir would be opened, and the navigation would thus follow the course of the river without passing through the locks. This is the system adopted in some of the latest navigation works on the Continent of Europe and in America, and is very suitable for such a river as the Darling, where permanent weirs and locks of high lift would be inadvisable, not only on account of the great cost of high weirs that would resist the action of high floods, but also because it is undesirable to materially increase the height of the maximum floods.

Dimensions

---

* The diagram is drafted on scales 20 ft. vertical and 10 miles horizontal to 1 inch. It shows the various levels of the river and position of locks from Wentworth to a point 30 miles north of Pamammaroo station, or to within 132 miles by river of Wilcannia, the length of river sectioned being 368 miles. The various heights and positions of the locks and the distances between them are as follows:—

1. Wentworth; 8 ft. lift
2. About 10 miles below Tapio station; 6 ft. lift; distance, 23 miles.
3. About 6 miles below Para; 5 ft. lift; distance, 34 miles.
4. About 7 miles above Para; 6 ft. lift; distance, 18 miles.
5. About 19 miles further up; 6 ft. lift.
6. About 19 miles further up; 6 ft. lift.
7. 7½ miles below Malara; 4 ft. lift; distance, 18 miles.
8. A mile above Pooncarie; 6 ft. 6 in. lift; distance, 15 miles.
9. 17½ miles up; 6 ft. 6 in. lift.
10. About 2½ miles below Moorara; 4 ft. 6 in. lift; distance, 22½ miles.
11. 24 miles up; 6 ft. 6 in. lift.
12. 29 miles up; 4 ft. lift.
13. 17½ miles up; 6 ft. 6 in. lift.
14. 16 miles up; 4 ft. 6 in. lift.
15. 19½ miles up; 5 ft. lift.
16. 15 miles below Menindie; 5 ft. lift; distance, 14 miles.
17. 29 miles above Menindie; 6 ft. lift; distance, 44 miles.

Dimensions of locks.

8. The dimensions I propose for the locks are: length, not less than 200 feet; width, 18 feet; depth on sills, 6 feet inches; lift, 4 feet to 6 feet 6 inches. When a lock could be placed in a cut off, the length might be considerably increased, without materially adding to the cost. The lock-chamber should be of sufficient area to take one or more barges as well as the towing steamer, which should also be a cargo boat. The width of the navigable pass should not be less than 50 feet, and it would be opened as soon as the discharge was sufficient to maintain a depth of 6 ft. 6 in. through it. As the navigable pass would occupy about half the width of the river, and as it would always be full open during floods, the effect of the fixed portion of the weir on a high flood would be almost imperceptible. For instance, with a 15-foot flood in the river, the fall in the surface of the water in passing over the weir would be only 3½ inches.

Conserving water.

9. From my observations of the flow of the river at the time of inspection, I believe that the summer supply will at all times be sufficient to compensate for the loss by lockage and evaporation; but as by means of the weirs the anabranches and the lakes and lagoons situated back from the river could be more readily filled, and as the water could, by means of flood-gates and sluices, be retained in them until it was required, an abundance of water could, even in the driest years, be made a certainty, while the supply to the back country would be very greatly improved. Although it does not come within the scope of the inquiry submitted to me, I may be permitted to bring under the notice of the Board the importance of the subject of water supply, which I have reason to believe could be economically and profitably combined with the navigation project. In the near future, no doubt, irrigation also will have to be undertaken to some extent, but at present the value of an abundant supply of water for stock is alone of great consequence.

10. Inland navigation, after having for some time been almost at a standstill, owing to the rapid extension of the railways, has of late years experienced a revival both in England and more especially on the Continent, its numerous advantages, more particularly the low cost of haulage and of maintenance, enabling it to contrast favourably with railway traffic. When a river is canalized and the navigation is independent of floods and drought, the one great advantage of railway communication —its regularity—disappears, while the carrying capacity of a canal is much greater. The total cost of carriage on a canal or navigable river decreases in a far greater ratio with the increase of traffic than does that by railway. In the *Contemporary Review* for April last General Hamley writes—"Fifteen years ago it would scarcely have been disputed that canals must give way to railways. The teaching of to-day is, however, quite different. There is a widespread belief that inland water carriage may compete successfully with railways, and a very general desire to bring the former mode of transit into more extensive use." It has, in fact, been found advisable, even where railway communication already exists, to construct lines of navigation, or to improve rivers, at a cost of from £7,000 to £11,500 per mile.

Estimate of cost.

11. The following is my estimate of the cost of the works above proposed:—

Locks with weirs and navigable passes, twenty-one at £10,000, and one at £20,000	£230,000
Deepening shallows	30,500
Clearing banks of trees and snagging	6,500
Works to billabongs, back-waters, &c.	6,500
Wharves, cranes, &c.	6,000
Contingencies and engineering	30,500
	£310,000

The annual expense may, I think, be stated as follows, exclusive of interest on capital:—

Lock-keepers, twenty-two at £125	£2,750
Repairs and maintenance	3,000
Management	1,500
	£7,250

12. By the above-described system of lockage, all the steamers now navigating these rivers except six sternwheel steamers would be excluded from the navigation in the low states of the rivers, as they are at present, but thirty of the barges, with a gross tonnage of 1,712 tons, could pass through the locks. By means of the navigable passes all the vessels now navigating the river, drawing 6 ft., could continue to do so when there was an 8-ft. fresh in the river.

13. By reducing the depth so that only vessels drawing not more than 4 ft. could navigate the locks, I think the cost could be reduced by about £40,000. To increase the navigable depth in the river and locks would require a much greater proportionate increase in the cost. I do not think the locks should have a greater width than 18 feet. The navigable depth to be adopted should, however, be regulated in connection with possible improvements in the Murray, but I do not think it should exceed 6 feet. Similar dimensions of locks to those recommended are found equal to a traffic of 1,000,000 tons per annum.

Melbourne, June 5, 1883. G. GORDON.

APPENDIX D 15.

RIVER DARLING.

PROBABLE Cost of a Timber Weir to raise the water for the purpose of diverting it to the back country.

Probable cost of Weir only	£9,500
If the navigation had to be provided for, the *extra* cost of cutting a Canal, with a flight of Locks at its lower end, in a favourable position, above the estimated cost of the single Locks that would otherwise suffice for the navigation, would probably be	2,000
	£11,500

G. GORDON.

LOCKS ON THE DARLING.

My estimate of the cost of a Lock on the river Darling, 200 feet long, 18 feet wide, depth 6 feet 6 inches on the sills, with a lift of 6 feet, constructed of concrete and masonry, was £8,000.

The cost of Weirs for navigation only, corresponding in height to the above Lock, and built in 3 feet of water, so that the crest would be 9 feet above the bed of the river, was estimated as follows:—

1. Concrete and stone on rocky bed	£17 10 0
2. Timber Weir on sandy bed	15 0 0
3. Do do clay do	11 10 0

All per lineal ft. of fixed Weir, and the average was taken at £14 4s., No. 2 being the most usual case.

The movable part, 50 feet wide (Poirée's Needle Weir), was taken at £20 per lineal foot.

The length of the two parts would generally be over 100 feet.

To the above has to be added £350 for abutments and wing walls.

G. GORDON.

APPENDIX D 17.

APPENDIX D 17.

LOWAN SHIRE WELLS.

THE depth of the Wells varies from 129 feet to 196 feet to the water, the average being 161 feet.
The cost of dry sinking, 25s. to 28s per foot (double shaft timbered).
Cost of wet sinking in chamber at bottom, £3 to £10 per foot; average, £6.
Average cost of windmill pump, iron tank, and troughs, &c., £250.

G. GORDON.

APPENDIX D 18.

Cost of Impounding Water in large Reservoirs in Victoria.

	Name of Reservoir.	Capacity in cubic feet million.	Cost of Work, including Outlet Works and Compensation for Land.	Cost of Storage per million cubic feet.	Remarks.
			£	£ s. d.	
1	Warranga Basin	3,690	62,270	17 5 11	To be fed by an artificial channel estimate—not constructed.
2	Yan Yean	1,024	150,000	146 9 8	
3	Malmsbury	465·4	100,375	215 14 0	
4	Barker's Creek	100·7	34,017	337 18 4	
5	Spring Gully	40	12,443	311 1 10	
6	Stony Creek	152	50,548	332 8 6	
7	Average of 6			223 18 7	

APPENDIX E 2.

Mr. J. Gregson to The Government Astronomer.

Sir, Newcastle, 16 December, 1879.

I venture to take the liberty of writing to you in reference to the subject of your letter of 10th inst., published in Saturday's *Herald*, for the purpose of mentioning that considerable tracts of country adjacent to the main Dividing Range are watered by springs whose sources, like those of the Darling River wells, must be distant.

A spur of the main range divides the waters of the Comet and Negoa Rivers in Queensland, the line of the watershed having an average course of about north and south, in longitude 148°. The formation is porphyritic, the western slopes being of basalt, the eastern decomposed sandstone and conglomerate. The ridge attains a height of 500 feet above the surrounding country, which itself lies about 1,500 feet above sea-level. The main range, or that portion of it called Buckland's Tableland, lies 40–60 miles to the south, the summits here being fully 2,500 feet above sea-level. The western slopes of the spur I speak of are drained by watercourses in which are streams running all the year through. These streams start from springs, and are often a mile or more in length before the water disappears underground.

I resided in this district for years, and have often amused myself with estimating the quantity of water which flows from this ridge, satisfying myself that, as its volume was vastly more than could be supplied by rainfall thereabouts, the water could only come from a distant source, which I suppose to be the interior of the continent.

Much the same thing is to be seen about the Liverpool Range, in the neighbourhood of Cassilis. There are on the south side of this part of the range the Munmurra, the Krué, the Wybong, the Dartbrook, and the Page, all tributaries of the Hunter, which have in all seasons streams of water (though in dry times the water is only found in the gravel-bed), and I am much mistaken if more water does not pass along these streams and in those on the opposite side of the range than is supplied by the rainfall on the neighbouring high ground. As in the instance above mentioned, it has often struck me that the water has found its way from the great plains of the interior.

The fact you mention, that from wells between Wilcannia and Bourke the water has risen to a height of 26 feet above the surface of the ground, seems to me to corroborate the idea. Would it be a very wild stretch of the imagination to suppose that the plains of the interior lie like a crust upon the surface of an immense lake, rising with the supply of water in flood-time from such rivers as the Barcoo and Thomson in Queensland, and the more southern Darling River, and falling as this supply is gradually exhausted by such outlets as those I mention?

However this may be, it would be an interesting speculation as well as a useful one to inquire where the water does come from, and I hope your communication to the *Herald* may have come under the notice of some whose attention being turned to the point may be able to throw some light upon it.

I remain, &c.,
JESSE GREGSON.

APPENDIX E 3.

[*Extract from Minutes of Proceedings of Intercolonial Meteorological Conference, held at Melbourne*, 1881.]

EVAPORATION.

Mr. H. C. Russell reported that, having for the past ten years carried on observations with three forms of evaporators, he thought the condensed results might be of interest to the members of the Conference. He mentioned that observations with the glass evaporator were begun at Sydney Observatory in 1860, but it was not until 1871 that the other two forms were placed beside it for the purpose of comparison. It was simply because the glass instrument was the one in use that it was assumed to be the standard for comparison, and not for any advantage in form or substance which it might be supposed to possess. The tin one had been adopted for use in the country because its cost was little, and the large one was started because it seemed to put the water into the condition which obtains in an ordinary open reservoir. The following details will form a sufficient description of these instruments:—

No. 1.—A glass vessel, standing on the ground, 8 in. high and 8 in. in diameter, in which the water is usually about 6 in. deep; it is read by a vernier scale attached to a point which is every morning made to touch the water by screw motion.

No. 2.—A tin vessel, painted white, standing on the ground, 12 in. high and 8 in. in diameter, in which the water is usually about 8 in. deep; the amount of evaporation is ascertained by weighing it every morning.

No. 3 is a galvanized iron vessel, sunk into the ground 2 ft. 4 in.; it is 2 ft. 6 in. deep, and 4 ft. in diameter. In it is a small float, to the top of which is attached a light vertical rod passing through two guides; this is graduated to tenths of an inch, and read to $\frac{1}{1000}$ of an inch by means of a microscope fixed on a firm support. The edge of the vessel is only 2 in. above the ground, to prevent surface water from running into it; and the grass is allowed to grow level with the top, to prevent rain splashing in, and sun-heat on the metal outside.

The table herewith shows the result from each evaporator, together with temperature, humidity, wind, and rainfall, for ten years, 1871 to 1880. It will be observed that the tin one shows the greatest amount, the glass second, and the large one least, on the average for ten years; but it is worth noting that in 1876, when the velocity of wind greatly exceeded other years, the tin one gave the evaporation only 7 per cent. above the average, the large one 20, and the glass 28 per cent.

Observations on the temperature of the water in the evaporators show that the glass one is most affected by the sun, the tin next, and the large one least.

In the course of the experiments the question arose whether more or less evaporation took place during the day as compared with the night. The day was divided at 9 a.m. and 9 p.m., and the observations confined to the glass and large evaporators; and it was found that the glass one gave 42 per cent. more during the day than during the night, and the large one 18 per cent. more during day than night, and it sometimes happened that it was more during the night than during the day. The result of these observations may be expressed in another way: Comparing the two, the large one gave 13 per cent. less than the glass one during the day, and 23 per cent. *more* during the night, which seems to prove that the heat absorbed by the large one during the day was given off in vapour during the night, and not by radiation from the sides, as in the glass one.

Year.	Shade Temp.	Humidity.	Miles of Wind.	Total Rainfall.	Evaporators.					Large greater than Glass.
					Amount in Tin.	Tin greater than Glass.	Amount in Glass.	Large less than Glass.	Amount in Large.	
1871	62·4	74·9	96·821	52·147	65·756	22·785	42·971	9·643	33·130	In May and June Large greato than Glass.
1872	62·6	75·9	98·830	37·001	66·589	25·001	41·588	11·495	30·093	Greater in May.
1873	63·0	75·9	91·306	73·263	54·622	6·761	47·861	18·427	29·432	
1874	63·0	75·6	97·651	63·478	59·622	8·682	50·940	18·934	32·006

Another question presented itself, and was answered by several months' observation. It was—What ratio does evaporation in the shade bear to that in the sun? The shade chosen was the thermometer-shed, where the air has free access, but there is complete protection from the sun. The mean result of the measures was that 26 per cent. less evaporation took place in the shed than in the glass evaporator in the sun; or, comparing it with the large one, the result in shade was 9 per cent. more than in the large one; but, as the shade evaporator was placed 3 feet above the ground, where the air would probably be drier than on the surface of the ground, where it affects the large evaporator, it is probable that a small evaporator in the shade would give about the same result as one 4 feet over and sunk into the ground.

It will appear from what has been said that every change of condition under which evaporation is measured produces a change in the result, and since the conditions are infinitely variable, so the results must be. Therefore, before any comparable results can be obtained, we must determine what it is that we want to measure. Is it the evaporation from water in the ground, from water in a glass or metal vessel on the ground, or from water at some distance above the ground? For the mere purpose of comparison, any one of these positions would do, but since the one in the ground comes nearest to the condition of a natural reservoir, I prefer it, because the results would be directly useful for a practical purpose, as well as for science.

APPENDIX G 1.

FRIDAY, 14 *DECEMBER*, 1866.

Present:—

MR. FORSTER, MR. HAY, | MR. MATE, MR. PHELPS.

THE REV. J. D. LANG, D.D., IN THE CHAIR.

William Christopher Bennett, Esq., M.I.C.E., called in and examined:—

309. *Chairman.*] What is your designation? I am Commissioner and Engineer for Roads.
310. I understand you have resided for some time in the Riverina District? That is a mistake; I have been there on duty.
311. You are acquainted with the country generally? I am acquainted with the country generally; my duties take me all over it; I have been up there recently; about three weeks ago I was at Albury.
312. Are you acquainted with the character of the country between Deniliquin and Echuca on the Murray River? Yes.
313. What is the distance between those two points? It is somewhere about 50 miles, more or less.
314. What is the character of the intervening country, as likely to be applied to any agricultural purposes? All that country is suited for agricultural purposes, provided it be irrigated—perhaps the finest agricultural country in the world—but it would require to be irrigated on a large scale, as is done in India, to make certain of crops.
315. Would it be practicable to have irrigation from the distance to any water supply? It is a matter I have been employed upon in my early days, and have given a great deal of attention to the subject. The similarity of the country between the Jumna and the Ganges, and of that between the Murray and the Murrumbidgee, is remarkable indeed.
316. Do you think the value of the land, as being likely to be made available for agriculture, is at present an element of sufficient importance to take into account, in contemplating the construction of a railway—would any considerable amount of revenue be derived from the sale or from the use of the land for agricultural purposes? I have no doubt that large quantities of land would be sold, but I am doubtful as to the permanent success of agriculture there unaided by irrigation; it would be uncertain.
317. You do not think that that element of inquiry is of sufficient importance to be taken into account, in considering the ways and means for the construction of a line of railway? Not the agricultural element alone. Unaided by irrigation, think the country more suited for pastoral than for agricultural purposes.

318. Are you aware of the probable cost of a line of railway along that country? I could not give you a strictly professional opinion upon that, because I have not surveyed it, but I could give a surmise. I should think the cost of a railway ought not to exceed £6,000 a mile there; and when I say that, I mean a first-class permanent way—and I could not recommend any other—with moderately cheap stations.
319. What do you think are the necessities of the case that induce the parties interested to move for the construction of a railway;—is it necessary under present circumstances for that tract of country? There is a very great trade there.
320. And is that trade increasing? Yes; but I should be allowed to qualify this answer, by stating that I think the making a railway there would be a very suicidal act on the part of New South Wales. Already the traffic goes to Melbourne more than one interested in the prosperity of New South Wales desires.
321. Do you think we can help that, in the ordinary course of events? Yes, by concentrating all the resources of the Colony in making a railway to Wagga Wagga, with the ultimate prospect of a branch to Deniliquin.
322. Do you not think that the tendency of the commerce—of the traffic—in that part of the country, is towards the Murray River? Yes.
323. The natural tendency? The tendency is so, but I can hardly apply the word "natural" to it, because the course of commerce will go through the arteries provided for it. I think the tendency of the commerce to Melbourne is owing to the apathy of the Sydney community, who do not sufficiently know the value of that country.
324. Do you think this tendency could be easily counteracted by the Government of the Colony of New South Wales? If the Legislature were as firmly convinced as I am of the value of that country to New South Wales, I am sure it could.
325. You are not favourable, therefore, to the construction of a railway through that line of country? No, not until it is connected with Sydney.
326. You are not aware of the amount of traffic at present on the line? It is very great.
327. *Mr. Phelps.*] Do you consider that if a railway were made from Wagga Wagga to Deniliquin, and Wagga Wagga were connected with Sydney, that the trade would come to Sydney? Yes, because of the break of gauge. If you had goods to send away to port from Deniliquin, you would not send them on the railway to Echuca, to have them there transshipped to Melbourne. At the time of the battle of the gauges in England, it was considered that a change of gauge was equal to an additional distance of 50 miles; so that this would be practically moving Deniliquin 50 miles nearer Sydney.
328. Do you think it would be done more cheaply than carrying wool by dray from Deniliquin to Echuca? The carriage to Sydney?
329. Yes? That would depend upon the traffic arrangements on the Sydney Railway. It might be to the interest of the Sydney Government to carry wool from Deniliquin to Sydney cheaper than from Wagga Wagga to Sydney, to induce the traffic. Such things occur in England. In some places goods are carried at a cheaper rate for longer distances than for shorter, from points where opposition is likely to arise.
330. You would not think it advisable, supposing this railway were made from Deniliquin to Echuca, to have it on the Victorian gauge? Most decidedly not; it would practically be handing the country over to Victoria, as not only would it extend the radius of Melbourne influence 50 miles further ——
331. *Chairman.*] Is there not an Act of Parliament limiting the extent of the gauge in this Colony to all railways constructed within it? Yes; but if a special Act were passed for Deniliquin it would override that.
332. That is the state of the law at present? Yes. Then there is another question of some importance with reference to the gauges. In England, where two gauges are laid down, on account of the great difference in them there is very little difficulty in laying down a third rail; but here the gauges are so close that I think it would be attended with some difficulty and inconvenience; so that, practically, if a broad gauge were laid down to Deniliquin, when our line came there, it would be necessary to take up the broad gauge and put down the narrow.
333. *Mr. Phelps.*] You mentioned, some time ago, that you qualified your answer by saying that it would be a disadvantage to New South Wales to allow the traffic of the country to go to Victoria; but supposing this country cannot be developed unless this traffic and produce go to Victoria, would you under those circumstances still object to the railway? But I cannot admit the possibility of that supposition—I think the country can be developed; it is a point I have given great attention to during the time I have been in that part of the country.
334. New South Wales might lay out two millions to connect it with Sydney, when £200,000 would connect it with Melbourne? Yes, but New South Wales might lose a much larger sum than two millions by avoiding that expenditure.
335. In what way do you think New South Wales would lose it? In the countless ways by which traffic makes money; in revenue, in profit on sales, on imports in Sydney. The making of this railway would be practically handing over the country to Victoria, and it would be better to hand it over *de facto* than nominally to hold it while the real benefit of occupation was derived by Victoria.
336. Would you then assume that the interests of the people in that part of the country are to be neglected, in consequence of the difference of interest of Melbourne and Sydney? No, but I speak in the interests of the larger population of New South Wales; and I think in this case, as in all others, the rule must be applied that the interests of the minority must yield to those of the majority.
337. Then you think that this difference of gauge creating an obstruction between New South Wales and Victoria is rather a benefit to New South Wales? Until the railway system is thoroughly developed, I do; it will be an inconvenience then.
338. *Mr. Forster.*] Have you any interest in this railway? None whatever. I am a Government official.
339. Do you think this will be a paying railway? From Deniliquin to Echuca?
340. Yes? Yes, I do; it will pay well, but it will cause the Colony much greater loss in another way.
341. I mean the undertaking as a matter of investment for capital—the undertaking itself. Supposing what is now proposed were carried out, do you think it would be a profitable undertaking to the shareholders? Yes.
342. Then, in fact, you suppose that this Company would get on without any Government assistance? I have not read the prospectus of the Company, but I have a general idea that the project will be a remunerative one.
343. Then it would not require Government help. You say it would be a profitable undertaking;—do you think it would be so without Government help? Yes.
344. That is, so far as the profit of the undertaking is concerned, you do not think the promoters would require to be assisted by a subsidy? Decidedly not.
345. Do you think it would be for the interest of the Colony to subsidize the line, from other points of view? No, I think it would be to the interest of New South Wales to make it on the New South Wales gauge, so that we might ultimately work it.
346. You say that it would be a great loss to New South Wales in other respects, I suppose by the withdrawal of traffic? Yes, by extending the influence Melbourne has over the southern part of New South Wales, which is too great already.
347. I presume this loss would arise from the private interests of individuals directing them to avail themselves of a better line of traffic than they have at present? Yes.
348. It would be simply private interests directed in another channel? Yes.
348½. Do you think this railway would be injurious to the district? No, railways must be a benefit to any district.
349. Would it be a particular benefit to those whose traffic naturally flows either to Melbourne or down the Murray? Yes, but I cannot admit that word "naturally." The traffic will flow in the arteries that are made for it, and a railway is not the *natural* course of a traffic, as that is an *artificial* work.
350. When I speak of "naturally," I do not allude to these artificial lines of communication at all; but taking a new line of country, where no road is made at all, we find the settlers send their wool and receive their stores, some by one line of traffic and some by another; in some cases traffic without any artificial road would come to Sydney, in others to Melbourne—that is what I mean by natural. If you make a better road, you will make a difference in the line of traffic. In that sense, may it not be that those localities whose natural connection in the way of traffic would be with Melbourne would be benefited by this railway? Yes, they would be benefited by it.
351. *Mr. Hay.*] You have spoken of the possibility of developing this district by irrigation? Yes.
352. And have given strong opinions with regard to its capability. Have you examined the character of the country in a geological point of view? Not in a geological point of view. I have looked at the surface soil, and seen what it produces near Albury, and as far as Corowa, and I never saw finer.
353. Do you think there is any resemblance in the character of the country at Albury and Corowa, and that which lies lower down the Murray and Murrumbidgee? The country changes in its character—the soil is lighter.
354. Have you passed from Deniliquin to Hay? No.
355. Because you spoke of the character of the whole of the country? That was as to general configuration with reference to the river.

356. You spoke of the whole of the country between the Murray and the Murrumbidgee as being similar in its character to the country between the Jumna and the Ganges? I spoke as to its physical character—not as to its soil.
357. As to its configuration on the map? Yes.
358. You have not examined the country? No, not the soils.
359. You have passed over the country between Echuca and Deniliquin? Yes, and between Albury and Deniliquin.
360. Not to the north or west, or directly to the east of Deniliquin? No.
361. Have you examined the line between Echuca and Deniliquin? No.
362. You are not aware of the geological character or nature of the soil there? No, except that I understand that it is something like the soil in the vicinity of Deniliquin.
363. In what season of the year have you visited it? I have been there three or four times—I could not tell exactly the season of the year.
364. *Mr. Phelps.*] Was the country dry or green? It was dry at one time, and at one time tolerably green.
365. *Mr. Hay.*] You have not examined it with a view to the effect of the season? No, except that I saw it suffer very severely from drought.
366. When you say you have paid a great deal of attention to the subject of irrigation, do you mean irrigation in the English sense, where running water is led over pastoral lands, for instance; or in the Indian sense, where whole fields are submerged? In the Indian sense. I have been studying lately what has been done there in the way of irrigation.
367. In that particular kind of irrigation you allude to, it is necessary from time to time, and for a considerable period of time, to submerge the whole of the cultivated lands, is it not? Yes, partially to submerge them.
368. What do you mean by partially submerging them? Not to entirely cover them, but to let the water flow over the surface, not to cover them for any great depth.
369. To cover the land for a few inches, so as to saturate the soil? Yes.
370. I think the land you have referred to is approaching to a flat? Yes.
371. Have you ever made any calculation as to the quantity of water necessary to saturate soil of that description? I have not gone closely into that.
372. I suppose you have studied the subject enough to know, however, that it would take a large quantity of water indeed? Yes. In my earlier experience I had very much to do with works of that character—drainage and navigation, and dealing with large quantities of water.
373. Have you ever made any calculation as to the quantity of water in average seasons which could be supplied by the Murray? At the Murrumbidgee I have had the minimum quantity of water taken; at the Murray I have not been able to get the exact minimum; but the quantity in the Murrumbidgee is one-tenth the quantity taken out of the Ganges, at Hurdwar.
374. What do you mean by the minimum? At the very lowest state of the river I have had the discharge measured at Gundagai.
375. At what particular season? Last season, when it was very low—lower than it had been for many years.
376. Did you ever ascertain what had been the lowest quantity of water known in the Murrumbidgee at Gundagai? I believe it was the lowest, when measured, that it had been known for many years.
377. Do you know the Tumut River? Yes.
378. It is not a very large river? No.
379. Do you know the Murrumbidgee a little above the Tumut? Yes.
380. Do you know that the Murrumbidgee immediately above the Tumut has been known to stop running altogether? On the surface?—I did not know that, but it may have done so on the surface, and yet there may have been a considerable flow beneath. Last year it was stated to be very low indeed.
381. Did you ever hear it stated that the Murray and Murrumbidgee, at Gundagai, have been fordable by a man on horseback for a whole year? No; but even if they were fordable on horseback, there would still be a considerable quantity of water flowing on.
382. I suppose, from the study you have given to the subject, you would be of opinion that the capability of this region would depend upon the character of the soil partly, and partly upon the supply of water which was available to flood these large quantities of land? Yes.
383. Suppose that this region were capable of such development, have you ever made any calculations as to the difference which would be made by compelling the whole of its traffic to be conducted with Sydney in the place of Melbourne, from the increased distance? No.
384. Have you ever made any calculation as to the expense of making a railway from Goulburn, say to Hay, as about the nearest place to Sydney, that would tap that district? Not to Hay; my knowledge of the country is more between Goulburn and Wagga Wagga. I suppose the country is very much the same—it is a mere matter of length.
385. There is a great deal of mountainous country between Goulburn and Wagga Wagga? Yes.
386. Have you formed an opinion of the expense of a railway from Goulburn to Wagga Wagga? My opinion in railway matters is not of much worth, because my experience in railway making is not great, but I should think the country between Goulburn and Wagga Wagga is not more difficult than, if so difficult as, the country between Goornong and Albury on the Victoria side, which is estimated at £6,000 a mile.
387. That is all a flat country between Albury and Goornong? Yes; but to Beechworth, that is not flat. That is estimated to cost £6,000 and £1,000 for rolling stock, and £1,000 for stations, sidings, &c.
388. Did you ever ask Mr. Whitton what would be the expense of a railway from Goulburn to Wagga Wagga? No.
389. He has had a survey there? They were very preliminary lines.
390. Are you not aware that the surveys between Goulburn and beyond Yass showed very great difficulty indeed in the formation of a railway? No, I am not aware of it—I think that report must have been made some years ago, before they were able to make railways up such steep gradients.
391. Taking into account the gradients upon the Sydney and Goulburn line of railway, do you think the expense of the traffic conducted as between Goulburn and Sydney would be greater or less than that between Echuca and Melbourne—the distance between Echuca and Melbourne being a little longer, would the expense on the whole be greater or less? They have a much larger interest upon capital to pay in Victoria.
392. I am taking it independently of that—as to the expense of haulage? The haulage would be cheaper on the Victorian line.
393. Wagga Wagga being about the nearest point to Sydney in this district, and Echuca the nearest point to Melbourne, and the expense of transmitting goods from Echuca to Melbourne and from Goulburn to Sydney being about equal, there would then, I take it, in order to bring goods from Riverina to Sydney, be the expense of transmission from Wagga Wagga to Goulburn over and above the expense of taking them from Echuca to Melbourne, supposing the railway were completed? Minus the 50 miles which the difference of gauge would give you.
394. I am not talking of that at all, but taking simply the question of the transmission of goods from these districts. By allowing the people in these districts to make their own railway, it would be thus much cheaper to send their produce to England? Yes, provided you allowed the Victorian gauge into New South Wales.
395. So that, by compelling this district to avail itself of railway communication to Sydney instead of railway communication to Melbourne, it would be taxing to that extent, at least, the district? Yes, always provided no allowance were made in the cost of carriage on account of the peculiar circumstances of the case.
396. It would be an absolute loss? Yes.
397. Do you think there is any particular advantage to Australia, or to the world in general, equivalent to that in retaining this district in connection with Sydney, instead of allowing it to be connected with Melbourne if it likes? I have looked solely to the advantage of New South Wales; I have not considered it in so broad a light as that.
398. You have said that you thought this railway might pay as a private speculation; but do you think it would be desirable, supposing the district were separate entirely from either Sydney or Melbourne, and had its own choice—do you think it would tend so much to the development of that district to make a railway from Deniliquin to Echuca, that it would be worth the while of the district to give a subsidy for the construction of that railway? Yes, I think it would then.
399. Do not you think it would be a long time for this district to wait till a railway was made from Sydney even to Wagga Wagga? No, not if the railway were taken up in the spirit it ought to be.
400. Supposing we went on with it at anything like the same rate we have been going on with railway construction in New South Wales for the last ten years? In that case it would be a very long while.
401. In the meantime the development of this district would have to wait? Yes.
402. By adopting the Melbourne line the railway might go on from the present time? Yes, but it would practically be handing over the country to Victoria, and extending the radius of Victorian influence over New South Wales. 403.

403. Supposing the railway were made from Sydney to Deniliquin, and that the present railway were open from Echuca to Melbourne, would it be possible even then to bring the traffic to Sydney, if the inhabitants of the district were left at liberty to avail themselves of the railway from Echuca to Melbourne? It would be a work of time.
404. Do not you think it would be necessary either to prevent their making the railway from Deniliquin to Echuca, or to prevent them getting their goods from Melbourne altogether? I do not think these things could be for a moment thought of, and I do not think the making of a railway would bring all the traffic to Sydney at once.
405. Why should the people in the intermediate district prefer sending to Sydney to sending to Melbourne? On accoun' of the break of the gauge.
406. Is there any necessity for being any break of guage? I have always presumed that the New South Wales Government would not allow the Victorian gauge into our territory.
407. Do you not suppose that a private Company might form a railway with any gauge? It would be practically handing the country over to Victoria to allow the Victorian gauge in this Colony; it would be better to make over the country at once, and get a subsidy from Victoria, to be applied to the extension of our Southern Railway.
408. Or otherwise, to prevent a private Company, with the same gauge, to lay down a railway? Yes.
409. Do not you think, in the interests of New South Wales, you might go a little further—might it not be desirable, in the interests of New South Wales, to make a wall, or some perfect means of preventing any communication with Victoria whatever? No.
410. *Chairman.*] Do you think if such a system were established in these Colonies as exists under the German Custom-house, the Deutsches-Bund or Zollverein, so as to equalize the revenue from the Custom-house among all the Colonies according to their respective amounts of population, leaving the inhabitants of the different Colonies to find their way to the most accessible ports—do you think there could be any difficulty in managing such a system, or any loss to any particular Colony? My opinion on that subject must be taken for what it is worth, for it is a matter I have no knowledge of. I should think there would be no difficulty in adjusting the mere revenue, but I do not look to that so much as to the profit derivable from traffic.
411. Do you think any Government in this Colony could afford to carry goods from Deniliquin to Sydney by a railway, supposing such to be constructed, so as to compete with the shorter line to Melbourne? Yes, I think it would pay them to carry without any profit at all, on that particular portion, on account of the collateral benefits arising from it.
412. To carry goods free? Not free, but at the same rate as they would from Wagga Wagga, beyond the influence of Victoria.
413. *Mr. Phelps.*] What line do you think the railway will be most likely to pursue that will first join Sydney with Melbourne? The southern line.
414. To Wagga Wagga? Well, that I should wish to give a qualified answer to, for I have not a sufficiently intimate knowledge of the country to enable me to speak positively; but some point near Wagga Wagga, to facilitate the extension to Albury, because that is without exception the richest country in New South Wales.
415. Do you think it would be advisable to have the land reserved and surveyed before it is alienated? My impression on that subject is, that the Government ought to have the line surveyed at once from Goulburn, and also from Deniliquin, and also all the unalienated lands on either side, and to send some highly important person home—some person of the very highest standing in the Colony—to put the matter in the English market, and negotiate either for the transfer of the land or to give a guarantee. At all costs, however, the line to Wagga Wagga should be surveyed and made. This is not an idea which has been formed within the last month or two, but it has been gradually growing stronger and stronger in my mind for the last three or four years. Year by year I see the Melbourne influence creeping up, and Sydney being entirely isolated.
416. I wish to ask you some questions with respect to irrigation. Have you been in that country in India you have spoken of? No.
417. Over what areas do you think you could extend irrigation? The area embraced by the Ganges Canal is very near as large as that between the Murray and the Murrumbidgee. If the Committee wish any further information on this subject I should wish to prepare myself and give more definite information.
418. That would be an area, I suppose, of several thousand square miles? I should think the Ganges Canal must be 30,000 square miles.
419. Have you any idea of the extent that had to be artificially levelled? No; the greater part of the country between the Ganges and the Jumna is naturally level.
420. *Chairman.*] Is there not a great difference between that portion of India and these Colonies generally, in regard to the supply of water in each? The supply is larger in India. I have ascertained that there is ten times as much water taken out of the Ganges at Hurdwar as from the Murrumbidgee at Gundagai.
421. Do you think if our rivers are occasionally as low as Mr. Hay has stated, in the southern portions of the territory, these rivers would in ordinary seasons afford a sufficient amount of water to maintain the process of irrigation on an extensive scale? I think by properly constructed reservoirage, such a thing might be done. I wish to correct one statement in the petition before the Committee. It is stated that the sum of £618,000 has been expended on the Great Southern Road. Now, the amount expended since the first commencement of the Road Department in 1857, when the road was almost in a state of nature, to 31st March, 1865, is £219,000; and since that, £31,000; so that the amount to this day is £250,000 instead of £618,000.

APPENDIX G 2.

Statement by Mr. G. Mair, of Groongal, Murrumbidgee River.

Some years ago I ploughed up about 10 acres near a lagoon on this station and sowed a portion in lucerne, a portion in prairie grass, a portion in maize, and a portion in oats.

The soil, although rich enough, is rather stiff and clayey, and it was very imperfectly broken up when the seeds were sown; the consequence being that the crops came up very unevenly, but all the plants that did come up grew very luxuriantly.

I irrigated the patch by pumping the water by means of a 12-inch centrifugal pump, and a 12-horse power engine from the lagoon into a raised channel carried round the higher side of the land; from which channel the water was allowed to overflow, by making breaches at intervals in the bank, spreading itself about until all the land was saturated. The ground is almost a dead level, so that there was little difficulty in distributing the water over the surface.

I watered it about five times during the summer months, giving it on each occasion a soaking which I should think equal to 2 inches of rain or thereabouts.

The maize crop grew well to a height of 8 or 10 feet, and the cobs of corn were of good size, but I kept no record of the quantity gathered. The lucerne and prairie grass were fed down with sheep, and the oat crop, a very fine one, was cut down for hay. The lucerne is still growing, and thrives well. The prairie grass died out last summer, when I did not irrigate it.

The primary object of my experiment was attained in satisfying me that crops of all ordinary kinds suited to the climate can be grown in great abundance in this district by means of irrigation, but I could not pretend to give anything like an accurate estimate of the cost per acre of laying down and watering, or to speak with anything like authority as to the profitableness or otherwise of the work.

I am inclined to think that ordinary agricultural products of a compact and easily transportable kind, such as flour, would be more cheaply purchased elsewhere, and brought down by rail, than grown here under irrigation, but that irrigation might be profitably used for producing hay, which is bulky, and consequently expensive of carriage; or for raising potatoes or roots which are perishable, or green stuff to feed valuable stock on in time of drought.

I think also that wine-growing might be profitably carried on under irrigation, as vines thrive very vigorously here when liberally watered, and produce grapes of great richness and flavour.

One thing I may mention which may appear somewhat incredible to people who have seen the Murrumbidgee River only in time of flood, viz., that I think the supply of water in the summer-time would sometimes be found inadequate to very extensive irrigating operations.

The stream is frequently, from January to March, so shallow that a horse may ford it without wetting his knees, and

and of no great width; and from the quantity of water I have myself pumped up with one engine and pump for irrigating and sheepwashing purposes, I feel sure that if 500 or 1,000 other people were each withdrawing a similar quantity of water from the river, the stream would be found insufficient.

This drawback could of course be obviated by the construction of weirs to impound large quantities of water in the channel and prevent it from running to waste; but this work would probably be found too expensive to be undertaken until the country becomes very much more thickly peopled than it is likely to be for many years yet.

APPENDIX H.

Water Conservation, &c.

Paper read by John Wright, Esq:, before the Engineering Association of New South Wales, 23rd March, 1882.

The very protracted drought which I regret to say still continues in many parts of the Colonies is being severely felt by stock-owners and farmers, whose losses have in consequence been considerable, and unless we are favoured with a general downfall of rain many will be ruined. This is indeed sad to contemplate, and any suggestions that may be made or plans submitted with the view of guarding against a future loss from a like cause or mitigate the present state of matters should be received with every consideration.

That the various Governments recognize the vital importance of obtaining water in the interior is evidenced by the fact that all have during the last sessions of their respective Parliaments voted large sums of money for this special purpose, either by storage or tapping a subterranean supply by well-sinking and boring. The scientific Societies of the various Colonies have for years past collected valuable information in connection with underground supplies of water, and have promptly made the results of their investigation and observations as public as possible. Individual scientists have also from time to time given publicity to any discoveries they may have made, and generally treated the subject with an earnestness that cannot be too highly commended, and could only emanate from their having fully realized the vast importance of the subject and the influence it has upon the future welfare and development of the interior of our continent.

Scientifically, the subject has received and is receiving careful study. As instances of this fact, take the annual report of the learned President of the Linnean Society, and also the writings and reports of the Geological Surveyors, the Government Astronomer, the Government Geologist, Professor Tate, the Deputy Surveyor-General of South Australia, Messrs. Abbott, Sanger, and many others. The latest and most interesting discoveries are ably described by Dr. Cox in his annual report which I before mentioned, and all who read that report must feel convinced that there are immense subterranean stores of water in the interior which only require tapping to yield unlimited supplies, and that, with the aid of science, we can determine—(1st) where water can be obtained by penetrating a certain stratum which is known to underlie the surface in a particular locality; (2nd) the probable depth at which it will be penetrated; (3rd) where water cannot be obtained, the geological stratification and previous experience proving the impossibility of doing so.

These determinations of science are positive, and have quite recently been put to the test in two very different and distant localities—(1st) in the back country of the Great Australian Bight; (2nd) in Central Australia, a little to the west of the border of Queensland and South Australia.

Some time back it will be remembered that Professor Tate, Geological Lecturer at the Adelaide University, was engaged by the South Australian Government to report upon the possibility of obtaining a subterranean supply of water in the back country of the Great Australian Bight. After a careful examination of the country, the Professor arrived at the conclusion that there was no possibility or probability of obtaining such supply. The Government, however, acting upon the advice of their Surveyor-General, took a different view, and decided to send a large and expensive boring plant to test the question, the result being a decided triumph for science and the Professor, no water having been found and the work abandoned. 2nd. Mr. Sanger, in his report to the Surveyor-General of South Australia on the Geology, &c., of the country between the Government Gums and Cooper's Creek, says, in reference to the possibility of obtaining a water supply by boring:—

"As the great want of the country is a good supply of water, a few words upon the possibility of obtaining it perhaps will not be amiss. Surface sinking has been generally practised by the squatters, and has met with varying success—more frequently salt water has been obtained than fresh. When, however, fresh water has been obtained, the supply has generally proved to be variable, as it depends upon local rains. Wells are generally, in the sandhill country, sunk in the beds of the dry watercourses. I have not heard of any of them lasting over two or three dry seasons. This is no more than can be expected, as the water rapidly soaks away through the porous sand and limestone underlying the alluvial clay—in fact it is only the imperviousness of the blue marl that causes the supply to last as long as it does. With boring, the case is different. The sand and limestone can be passed through and water reached at great depths,—in the region between the Government Gums and Manuwaukaninna, boring would meet with success if attempted in any of the synclinal troughs indicated in the section. The basins are often many miles wide, and accordingly receive the drainage of a large extent of country. The water soaking through the tertiary beds accumulates on the hard impervious rocks below. If, therefore, boring was attempted near the centre of the basin the largest supply of water would be obtained. Any person possessing a knowledge of the rudiments of geology could at once recognise the synclinal basins, and by obtaining the dips of the beds on both borders of the trough the thickness of the beds and the depth at which the older rocks would be reached could easily be calculated. [Mr. Sanger gives a rule of calculation, illustrated by diagrams.] It is probable that the boring would have to be continued into the slate, as water will percolate through slate when it is cut up by cleavage planes, and such is the case with most of the slate underlying the tertiary beds between the Gums and Manuwaukininna. In the sandhill country a fine supply of water would be obtained by boring in any place through the tertiary beds of the older rocks. The boring would have to be carried to great depths however to reach the older rocks—probably at least 500 or 600 feet. But it is also probable that a fine supply of good water would be reached before that depth—in fact, as soon as the hard limestone formed in deep sea was reached. (See *supra*.) If such wells were established, they would do more to open up the country than anything else, and would also greatly facilitate the transfer of Queensland cattle to the Adelaide market."

Attached to the report is a note by the Surveyor-General:—"I fully concur from actual knowledge in the truth of most of Mr. Sanger's remarks."

The lessee of a large tract of country in that vicinity decided to try a few bores, and some three months ago I received a communication from him informing me that water had been struck in the 3rd bore tried, at a depth of 255 feet, quantity and quality fair. Awaiting further particulars, I presume the limestone in deep sea had been reached, and Mr. Sanger's predictions realized. The teachings of science have lent us valuable aid in solving many difficult problems in connection with underground stores of water which a few years ago seemed insuperable. Speaking as one deeply interested in the matter, I hope that we may continue to profit by science, and never neglect her aid in our attempts to obtain subterranean supplies of water. There are only two means by which we can secure a supply of water in Central Australia, or, as it is very appropriately called, the riverless country, and they are—(1st) storing the surplus rainfall in dams and tanks; (2nd) tap an underground supply by sinking wells and boring. In many parts of the Colonies the only means by which a supply of water can be secured is to store the rainfall in tanks or dams; the cost of doing so being always in proportion to the quantity or nearly so, and the quantity required is inversely as the acreage occupied; the selector or farmer requiring a larger quantity of water per acre than the squatter, though the holding of the former may only be 1-60th of the latter. I have had many opportunities in my travels through the Colonies of discussing the water question with both squatters and selectors, and was not a little surprised to find how few of either could, with any pretensions to accuracy, tell me how much water they would consume in any given time. They could tell me how long the last drought had lasted, from six to eighteen months, according to the locality, and they might experience one still more protracted; and I was even more surprised to find, that although they possessed this knowledge, they had not made anything like an adequate provision to meet the contingency. Out of curiosity I measured a number of tanks and dams upon stations and selections, and found that few would contain a sufficient quantity of water to tide their owners over a six months' drought. What then can they expect should the drought last for a greater length of time? Certainly nothing but disaster and loss. They possessed the remedy, indeed had it in their own hands, but failed to make use of it at the proper time. The result is that thousands of pounds have to be spent (really lost) in obtaining temporary

temporary supplies and affording temporary relief. Had the thousands now being lost, not only by the Government but by private individuals, been expended on permanent works, how much misery and loss would have been averted. In this matter the selector generally, but most unjustly, blames and abuses the Government for having sold the land without previously or subsequently securing them an ample supply of water. The very weak principle of looking to and awaiting for the Government to supply almost all local requirements of whatever nature they may be, has unfortunately obtained a wide-spread hold upon the minds of all classes in the Colonies, and in reference to this particular subject has certainly resulted in checking and discouraging any effort of individual or collective enterprise to supply the want. Example: A particular local improvement is found to be urgently required by the residents; a deputation is appointed to wait on the Minister; they are well received and a promise given that their wants shall be considered, &c., &c., then probably the matter ends; the people put up with what may be a great inconvenience, hoping every day that Government will do—well, what they ought and could have done themselves at first. Take the wants of Temora as an instance of this, the water supply specially, and could any one think it possible that such an important gold-field would, as it is to this day, be without an ample supply of water had the people been left to depend upon themselves and not upon the Government.

Governments can only move slowly unless pressed by emergency, and all must know how impossible it would be for any Government to undertake the provision of all local water supplies and carry them out within a reasonable period. The question as to whether they should undertake any such works is a debatable one. Our Colonial Governments could not possibly undertake the cost of providing general or national supplies of water such as the Indian Governments have done, but I think it would be wise on the part of each Government to come to some definite understanding with the people in regard to the water supply question. Existing arrangements are very unsatisfactory—a million being voted for the Sydney supply, and ten or twenty thousand for the interior. A recent writer suggests, "That the Government should decide definitely—the extent of help they are willing to give; to what extent people will be left to make their own provision; and the direction in which the most assistance will be given." Had any such regulations been in force in this Colony years ago, I think much of the loss and disaster brought about by the present drought would have been averted, because I feel assured that private enterprise would have provided water supplies for many who expected and considered it the duty of the Government to provide for them.

Tanks.

The selector is the greatest sufferer in time of drought, and his first and most important duty when taking up his selection is to provide an ample supply of water. The quickest way of doing this is to excavate a small tank or surface dam, the latter being more generally adopted, and in the majority of instances they are too small, too shallow, and too much exposed to be depended upon, because they soon dry up by evaporation alone; they should therefore be dug as deep as possible, the smallest water surface exposed to the atmosphere that circumstances will permit, and should in all cases be securely fenced, and, where practicable, covered. Many small reservoirs I have seen spoiled and rendered worthless through cattle and horses having free access to them. The limited area of selections generally is a great obstacle to the construction of large dams, either from the limited watershed area, or the want of natural facilities. The selector must in such cases resort to the construction of underground tanks to secure his supply.

The site of the tank should be very carefully chosen, the base of a gentle slope being the most suitable, and should be so situated as to be free from ever receiving the drainage of the stable, cow-sheds, sheep-pens, or other out-buildings connected with the house, but sufficiently near to be of easy access; and in order to ensure a supply from a very small rainfall, the sloping ground above the tank should be specially prepared in the following manner:—Remove the whole of the vegetation, say over an area of 60 yards square, with a sharp spade, taking care not to break or cut the natural surface more than can possibly be avoided; a roller if at hand should then be run over it, but if not, the loose places should be rammed or patted down with a light rammer or the back of the spade. The vegetation as it again grows should be carefully cut until it is altogether destroyed. In this way within a very short space of time, a hard and clean gathering ground will be formed, from which the water will run off almost as rapidly as from a shingle roof—very little loss being sustained from absorption—and with care it can easily be maintained.

The area I have given, 60 yards square, is about equal to ¾ of an acre, and is merely taken as per example, the size being dependent upon the quantity required to be stored. I have on several occasions clearly demonstrated that of a gathering ground such as I have described, it is possible to conserve 98 per cent. of the actual rainfall, whereas upon unprepared ground from 30 to 50 per cent. is lost by absorption. The cost of preparing the ground is small as compared with the advantages given, and the area can be increased in proportion to requirements. One man can prepare an acre in 2½ days. Any one who has had the opportunity or taken the trouble to inquire into the cause of the scarcity of water in many parts of the Colonies could only arrive at one conclusion, and that is—that such scarcity is in a great measure brought about by a want of knowledge of the quantity required, and the inadequate storage provisions made by the consumers. Now I think it would not be out of place to submit a few calculations that may be of service to many in the future; for domestic purposes, 3 gallons per head per day in the country is a fair supply—thousands now have to do with less—although more should in all cases be provided. Any consumer, whether squatter, digger, or selector, knowing the number of his household and the possible length of drought, can easily calculate the quantity of water he requires to store. Example: Say the household numbers eight, quantity consumed, 4 gallons per head per diem, length of drought, 300 days; he will therefore require to store $8 \times 4 \times 300 = 9{,}600$. A round tank 14 feet diameter and 12 feet deep will be of sufficient capacity to store that quantity, an ample allowance being made for evaporation, and each cubic yard excavated will store or contain 165 gallons of water (nearly). One inch of rainfall on half an acre of a properly prepared gathering ground, within twelve hours, would be sufficient to ensure that quantity being stored; one inch of rainfall upon an acre of ground being equal to 22,635 gallons. Underground tanks are I think also the best means of storing water for horses and cattle, because their actual wants need only be supplied, none going to waste as is the case if they have free access to the water.

The construction of underground tanks is, I need hardly say, an important matter; the circular form being decidedly the best, most economical, and easiest to construct. The earth is not of a sufficiently retentive nature itself to hold water without the aid of cement or lime to form concrete walls; and both those materials being dear, or not procurable, it is necessary for the selector to resort to clay puddle, which can be had for the making, and is in every respect equal to cement or lime for retaining water, if not exposed to the sun. Puddle-wall tanks are constructed in the following manner:—A circular excavation is first made, on the bottom of which is a layer of well mixed clay puddle, from 8 to 12 inches in thickness; upon this layer of clay the first course of brick or stone is carefully bedded; if stone is used, the thickness of wall should be 12 inches, brick, 9 inches; each course should be bedded or laid on soft clay puddle, the same as mortar, a space being left between the stone and earth-wall not less than 6 inches, which should be filled with stiffer puddle and well rammed, care being taken not to force the stone or brick out of position by the ramming. The wall should be carried up to about one foot above the surface and banked with ordinary earth, inlet and outlet pipes of wood being inserted a little below the surface level.

Tanks of this description cost in Queensland and South Australia from 1s. 10d. to 2s. 6d. per cubic yard of excavation. The materials required in their construction are obtainable almost anywhere at a very small cost. An ordinary labourer can do all the work necessary in their construction; and, as an expeditious and economical means of storing water, they are much superior to the ordinary surface reservoir or small dams now so largely used by selectors and others, and I would strongly recommend their more general adoption. Of course there is a limit to their economic utility as a means of storing and conserving water, but up to 150,000 gallons they are certainly superior in every respect to small dams and surface reservoirs; therefore their limit of utility will rarely be reached by the ordinary selector or farmer, and their more general adoption in the future would, I feel assured, mitigate many of the disastrous effects of a protracted drought.

Steam Excavators.

In those parts of the Colonies where a supply can only be secured by storage, the steam scoop or excavators recently imported to South Australia by Sir T. Elder and P. Waite, Esq., for excavating tanks and reservoirs upon their runs in the far north, are beyond all question the most expeditious and economical machines yet seen. Tanks of any size can be taken out by them to a depth of 30 feet or more, at about one-third the usual cost, and I most respectfully suggest that inquiries should be made by the authorities and private persons in reference to these machines, with a view to their immediate introduction into this Colony. I had myself statistics of their capabilities obtained when they were tested in Adelaide, but I have unfortunately lost them. Speaking from memory, I think their cost was something over £2,000; average daily work, 200 cubic yards; cost per yard being in proportion to the depth of excavation, the maximum being about 8d. per yard; and I think they are

now

now engaged in excavating tanks for the South Australian Government, on the road from Government Gums to Mount Browne and the Queensland border, at that price, viz., 8d. per cubic yard. The speedy manner in which they perform their work is certainly their greatest advantage, and their introduction would work wonders in many portions of the Colonies.

The steam excavators can only be worked where there is a supply of water, but they have been so designed as to use only a minimum quantity, and as they do so much work, a small supply of water will enable them to excavate a large dam or tank with a very small consumption of that element.

Dams.

The best mode of constructing dams has been so often discussed in the colonial Press that little can be said in reference thereto, still the following hints may prove of service to many who propose storing water by such means :—

In determining the site for a large dam, the feature of the ground and the material obtainable for its construction should be carefully considered, and should be as low as possible, in order to insure a large watershed area or gathering ground; the best site being where an embankment across a narrow gully or watercourse would embank a large basin. The material of the site of embankment should be either impervious to water or capable of being easily removed so far as they are pervious. A water-tight foundation should in all cases be secured. The best material for an embankment is dry clay, and should be put on in layers from 9 to 18 inches in thickness, the middle being kept lower than the face and back, and consolidated by ramming, dray traffic, or running a flock of sheep over it occasionally. The worst material for an embankment is a mixture of clay, sand, and loam, because the clay keeps the water in and the sand and loam absorbs it. All vegetable matter should be removed from the base of any embankment intended to impound water. The inside slope of the bank should not be less than 2½ to 1, the outside not less than 1½ to 1. The top of the bank should be perfectly flat, and not less than 3 feet above the highest water level, and should be as broad as ⅓ of the greatest height, and securely fenced, to prevent stock from treading it down. A channel should be cut at one end of the bank at the highest safe high-water level, of a sufficient capacity to carry off all the flood-water above that level as fast as it flows into the reservoir or dam, and of sufficient length to convey the water to such a distance as will not endanger the embankment and discharge itself again into the natural water-course. Dams that are not water-tight may in many cases be rendered so by ploughing or otherwise breaking up the surface covered by water, and, immediately after rain, running a large number of sheep over it.

Well-sinking.

A constant and good supply of water can in many places be obtained by sinking wells at a reasonable depth, especially in many parts of Riverina; and it would hardly be credited, although a positive fact, that twenty years ago the number of wells upon stations for 100 miles around Deniliquin could be counted on one's fingers. At that time a general belief existed that the country was hopelessly dry, that it was no use sinking wells, reference always being made to a well upon Warbreccan, at the "Crow's Nest," and another at Atkinson's Hill Plain. These wells had been sunk some years previous to my seeing them in 1862, but had never penetrated the water-bearing drifts. The supply they gave was truly limited, and the water unfit for domestic use. The "Crow's Nest" well was afterwards sunk deeper, and I have been informed that a good supply of water was obtained from it. Notwithstanding these positive proofs, I felt convinced that plenty of water could be obtained by sinking wells in any part of that country, and at a depth of from 20 to 100 feet, but I could not prevail upon any one to try. In 1864–5, by persistent argument, I induced Mr. R. Cauldwell, of Cobran, to sink a well at the Curran-hut outstation, and, greatly to the surprise of all, Mr. Lockhart the superintendent of the station in particular, good water in abundance was struck at about 26 feet. A few weeks after another shaft was sunk in the "Gotha" paddock, and one at the "Gums," all yielding unlimited supplies of good water. Since then water has been found at depths varying from 20 to 100 feet all over that portion of the Colony. Now, is it not possible that in some parts of the colonies a similar belief may exist, and be the means of deterring many, as was the case around Deniliquin, from trying to obtain a supply by sinking wells? With no desire to be censorious, I certainly think there are such places. I am the more inclined to take this view from the unsatisfactory answers received to the question I invariably ask, "Have you tried any wells about here?" The reply in one locality or district is "No, what's the good, the country's too dry." In another, "No, but I'm going too." In another "Yes." "A well was sunk over there (perhaps some miles away) by Mr. ——, but he got no water, so what's the use of sinking here?" In another, "Yes." "A well was sunk some years ago; it has water in it, but it is too brackish, &c.," and generally the matter to my mind is treated with too much indifference.

An underground supply of water may be obtained I think in many places by sinking wells, even where it is said such does not exist, but, like a lead of gold, it can only be found by prospecting, and I hope to see in the future a large amount of this description of prospecting done. It has resulted, I know of my own personal knowledge, in vastly improving the back country of the Darling, the plains to the west of Cooper's Creek, and in the north-western portions of Western Australia, and if prosecuted with intelligent vigour in the more settled districts must lead to similar results. While writing this paper, February 28th, I received an intimation from a friend in South Australia, that Mr. Frank Perry, of Orooroo, had struck a good spring of water in a shaft only 30 feet deep. This is in one of the driest parts of the Colony of South Australia. Water was never expected to be found under 200 or 300 feet, if found at all, and it certainly helps to assure us that by trying we may ofttimes meet with unexpected success.

"Where is the best place round here to sink a well?" is a question often asked, but not by any means easy to answer. In the lowest ground in the vicinity is a sort of general answer, though it must not be accepted as the best reply. Ascertain the dip of the strata, follow it as far as you can in its downward trend, and then try (*i.e.*, if the strata dip to the east, go eastward as far as you can follow without a break). No general rule can be laid down for guidance in this particular, with the one exception of attention to the dip of the strata. The whole thing is like prospecting for gold—*just sink and chance it.*

Boring.

Diamond drills, Peirce well-borers, and many other patents, we have been told for the last two years are going to work wonders for us in finding minerals and water. So far one may ask, "What have they done?" really little or nothing, and we cannot expect them to do much for some time yet, especially in the interior, on account of the necessary working plant being so heavy and expensive. That they will do much good I do not for one moment deny, and I should be glad to see them working everywhere; but while they are being introduced we still suffer, and it behoves us to make the best use of the appliances we have until the use of the Diamond drills becomes more general. The most important discoveries of subterranean supplies of water have been made with the common boring tools that have been in use for many years past. They may be rude and primitive in the estimation of boring machine patentees, but they have been exceedingly useful, and it is somewhat singular that their utility has not been availed of to a much greater extent. Doubtless their cost has had much to do with it, but this I have found to be greatly exaggerated, not by the manufacturers but by the persons who purpose using them. The general impression is that the cost of a common boring plant is between £150 and £200. How this impression has got abroad I cannot imagine, because it is so very erroneous. Any founder in the Colonies can supply the necessary tools to bore to a depth of (say) 200 feet for about one-third of that sum, or from £50 to £60. A very useful boring plant was supplied by a Sydney firm in October last, to go to the Paroo, for £57; its weight, including 10 lengths of 4-inch tubing, being only 16 cwt. 3 qrs; and several bores have been put down with it since that time from 80 to 175 feet in depth. Boring by hand cannot be carried to any greater depth than 150 to 200 feet advantageously, but, if necessary, a greater depth can easily be reached by sinking a shaft and working the bore from the bottom of it. Under any circumstances, boring from the bottom of a shaft is the most expeditious and economical way in which boring can be done, especially so where there is a great depth of alluvial to go through. Depths varying from 400 to 500 feet have in many parts of the Colonies been reached in this manner, without the aid of any skilled labour or patent appliances. Squatters, farmers, and miners form associations for the purpose of watching over and considering their respective interests, and money is liberally subscribed by them to defray the cost of doing so. The progress and future welfare of large districts in the interior depends mainly upon the water supply, a permanent supply being therefore of the most vital interest to all; and I would suggest the formation of local water supply associations, whose sole objects should consist in, if possible, securing a permanent supply of water for their district. Funds for the purpose would, I think, be readily subscribed, and it would be for the association to consider whether the sinking of wells, boring, or the construction of tanks and dams would be the better in attaining their object. Much valuable information

could

could be obtained on application to the Scientific Societies; and the Government would, I think, willingly send a scientist to advise such associations, and help them to determine the most suitable site for their operations. A few hundred pounds spent in this way would assuredly be productive of great benefit in many districts, and the necessary delay in waiting for the Government to undertake such works would be avoided.

A new boring machine, or a combination of two altogether different machines, has just been introduced by the South Australian Government, and is thus described in a recent report by an expert:—"At the waterworks yard in Adelaide the diamond drill (Docwra's Patent), and Mather and Platt's boring machine can be seen in successful operation; and from drawings and plans sent home by the hydraulic engineer, Oswald Brown, M.I.C.E., the Mather and Platt has been built to work in conjunction with the diamond drill, forming a most complete machine, and the only one of the kind in existence. It must be understood that the diamond drill works best in solid strata, and that where loose earth, gravel, or sand is met with, the drill is liable to clog or to be broken, and considerable delay is caused in the operation of sinking. With Mather and Platt's machine added the work can be prosecuted with more vigour and with a certainty of every obstacle being surmounted, whatever the nature of the strata that may be met with in going down to a depth of 2,000 or 3,000 feet. The majority of the diamond drills that are being used in Victoria for prospecting purposes produce a core varying from 2, 3, or 4 inches in diameter, but the Docwra machine will bore a hole 24 inches in diameter to any depth that may be required. Some idea of the magnitude of this boring operation may be formed when we realize the fact that in favourable country a man could be lowered through the largest tube to the depth of nearly half a mile below the surface. Not long since in the Chatham dockyard a bore was commenced at 23 inches in diameter and went down uninterruptedly to 750 feet, where it was necessary, on account of the shifting strata, to put down inner tubes and reduce the diameter of the core from time to time until the width was 13 inches at 900 feet, where water was struck. The New River Company in searching for water at Ware went down to 800 feet with an 18-inch core. At Collingham, in Nottinghamshire, a bore has been put down to a depth of 2,034 feet, and in Germany to a depth of 3,200 feet. In the two former instances the operations were under the superintendence of Mr. Thomas Ball, who has been engaged by the Government to superintend the machine of which we are writing, and who arrived in the Colony in October last. Mr. Ball has had some fifteen years' experience with diamond drills and boring machines of a kindred character, and he speaks in high terms of the one he is now using, which is most complete and fitted with all the latest improvements. The rods and tubes, however, which accompany the diamond drill are not of a size exceeding 12 inches in diameter, because for artesian well purposes the larger sizes are not required. As it has only within this last month been erected and tried, we cannot form any estimate of its capabilities. It has since been taken down and sent to Wilmington to bore for water. No particulars are as yet to hand of the progress it is making; judging from the trial, I should think it will fully realize the utmost expectations of Messrs. Brown and Ball.

Locking the Rivers.

Proposals have been submitted to lock our rivers, for the double purpose of securing an ample supply of water and constant navigation. Such proposals have, however, received little attention, in consequence of the enormous cost of the work, and the possibility of their greatly affecting present vested interests.

Irrigation.

Schemes for irrigating the great inland plains have been propounded by engineers and others at various times, but no works of that kind have as yet been undertaken. Some of these schemes were only possible upon paper, though seemingly elaborated with care and nicely wrought out, all of them being crude in the extreme, and evidently propounded without any knowledge of the physical or topographical features of the country which they proposed to irrigate. In laying out these schemes the propounders had evidently overlooked or were ignorant of the engineering laws which experience has taught us should be the first and most important consideration in all irrigation works. In no single instance had any surveys been made by the proposers, nor had they even examined the ground or land which their scheme was to benefit so much. The success of any such proposals depends entirely upon the area of land irrigated, and that could only be determined by first knowing the proper inclination to be given to the surface of the canal; and the only means of ascertaining that would, of course, be by actual survey. The profile course of a river having its rise in the higher lands and gradually flowing into the plains below describes a curve concave to the horizon throughout, but more inclined near its source than elsewhere, and as it occupied the lowest line in the valley through which it flowed, the elevated land on each side was, of course, entirely cut off from irrigation. The longitudinal profile of the irrigation canal leading out of any such rivers should be, as near as circumstances will permit, a regular inclined plane, whereby the altitude above the river valley was everywhere increased, except at the extremities, and the lateral high lands correspondingly governed, it being evident that the greater the elevation of the head of the canal the greater the area of land irrigation.

In order to give some idea of the crudeness and impracticability of some of the schemes, I will give you a few particulars of two that were submitted a few years ago:—One to irrigate the great plains between the Darling, Bogan, and Lachlan Rivers, by means of a *large canal upon the Indian principle*—whatever that may have meant—the supply to be taken from the Darling River about Bourke. It, however, fell through when it was discovered that the elevation of the land proposed to be irrigated was greater than the source. The summer water level of the Darling at Bourke is only about 360 feet above high-water-mark, Port Jackson; its fall per mile being a *few inches*, consequently it would only be possible to irrigate a very narrow strip upon either side of its own valley, that is, if the supply be taken from the river itself. The source of supply for any irrigation scheme should have a good elevation, in order to facilitate distribution; this cannot, I think, be obtained from either the Darling or Murray Rivers, though it may be possible in many others. A proposal was also made to irrigate the Murray scrub and supply the city of Adelaide with water from the Murray; it was, however, found that the Murray at Wentworth, some distance above the source of supply, was actually 130 feet below the city level, and about 150 feet below the scrub proposed to be irrigated. It may be of interest to many members of the Association to know that the summer water level of the Darling and Murray Rivers at their junction, is only about 9 feet above high-water-mark at the Murray mouth, or where it flows into the sea. The fall per 100 miles in the Murray River, from Wentworth to its confluence, is not more than 1 foot 3 inches. From 6 to 8 inches fall per mile being necessary for an irrigation canal, I think we may conclude that neither of those rivers can be utilized for irrigation purposes by means of gravitation, beyond, as I before remarked, a limited area upon either side of their own valley. Irrigation schemes, from their great magnitude, must necessarily be *national works*, and therefore, only within the province of Government to undertake. One of the best authorities upon this matter states, that—"It is almost useless to irrigate a valley unless it is first opened up by good roads and railways." Consequently, the question of undertaking gigantic schemes of irrigation will doubtless receive but little attention until our various railway systems are almost perfected.

It was not my intention to have said anything about irrigation in this paper, and I have only done so in order to show how chimerical some of the schemes submitted were. I will do the propounders the justice of saying that they acknowledge *being ignorant of the physical and topographical features of the country they proposed to irrigate;* at the same time I think they committed a grave error in proposing impracticable schemes, and I would strongly recommend any others who may be ambitious of treating the subject of irrigation, to sacrifice the theoretical for the practical. The difficulties which stand in the way of adopting any system of irrigation in Australia are more attributable to the physical features of the country and to the nature of the soil than to an absolute deficiency of water. We have from time to time been told of the great good that irrigation has done in Italy, India, Spain, and California, but you must know that the natural features of those countries are so essentially different from those which prevail in this continent, that systems of irrigation which become almost matters of course in those places are absolutely inapplicable here. The great difficulty we have to contend with in Australia is the finding of suitable sites for large reservoirs in which the water could be stored. Sites can be found and reservoirs made, but the question of cost is an important one, and one on which we possess no reliable information. One thing, however, is certain, and that is, that very little has been done in the way of storing large supplies of water anywhere in Australia, but I believe the time is not far distant when the water question will become as much a matter of State policy as railways now are. Irrigation works and the construction of reservoirs are too costly to be undertaken by the selector or digger. On a small scale the results have in no instance justified the outlay. Then the conditions under which pastoral lands are leased are not specially favourable to the investment of large sums of money in making reservoirs of a permanent character or very large dimensions. Hence my reason for concluding that national water supplies will become a matter of State policy, and, judging from the experience of other countries, they will certainly be reproductive works.

Weirs.

The construction of weirs near the confluence of the many creeks and watercourses that feed our rivers is a question worthy of very great consideration, both at the hands of the Government and the holders and lessees of the pastoral lands in the river country. From actual surveys which I have made on the Darling, Barwon, Warrego, Lachlan, Murrumbidgee, and other rivers, I know many places where a weir thrown across the confluence of a creek or watercourse would impound millions of gallons of water, not concentrated in one large basin, but extending miles into the dry back country. Any one who has been on those rivers during flood-time must have noticed the immense expanse of flood-waters, and the distance into back country to which the water extends, and have often heard it remarked, "What a grand country it would be if the water could only be kept at or near the flood-level." No effort has as yet been made to keep it, excepting in one instance, I believe, by Mr. J. Tyson. Many large and expensive dams have, to the credit of the pastoral lessees, been constructed, but their holding capacity is very small as compared with the quantity that would be impounded by the construction of a number of weirs in the creeks and watercourses, which intersect almost like a network the whole of the river country. Before submitting this proposal, I collected reliable data, at no little trouble and expense, upon which my calculation of the cost of the construction of the weirs and the quantity of water impounded, should be based. The following figures will, I have no doubt, surprise many members, but I can guarantee their accuracy. The construction of two weirs in a watercourse upon the west bank of the Darling River, at a cost of £2,990 each, would impound 7,000 millions of gallons of water (sufficient to supply the city of Sydney for five years)—cover at flood-level an area of about 14,000 acres—extend back from the river 18 miles—and give a water frontage of about 61 miles. The weirs being respectively 17 and 21 feet in height and 93 and 104 feet in length, and 8½ miles apart. In another place, a weir 60 feet long, 16 feet high, costing about £1,700, would throw the water back 16 miles, and impound upwards of 1,000 million gallons of water, and give about 70 miles of water frontage. It must not be imagined that results such as I have given would be obtained by the construction of weirs upon any or every watercourse or creek, but I feel assured that their adoption as a means of economically impounding immense quantities of water is vastly superior to dams. A dam is entirely dependent upon the local rainfall for its utility, which may be, and is, uncertain. The weir impounds flood-water, which occurs periodically, and can be relied upon to a much greater extent. The mode of constructing the weirs is important, and should, I suppose, be described in detail. On the Darling and some other rivers, stone not being so plentiful as at Pyrmont, we have to look around and obtain the best substitute, and that is cement, concrete, or beton blocks; their manufacture is simple and can be performed by ordinary labourers, and they possess the advantage of being easily moulded to any required shape and size. The component parts most suitable being one part sand, seven parts gravel or broken metal to one of cement, or eight parts of river gravel to one of cement. Gravel being found throughout the whole course of the rivers would be the material mostly used, and if well mixed with the cement in the above proportions, forms an artificial stone equal to the best sandstone; its cost being about 1s. 3d. per cubic foot.

The section of the weirs should be in all respects similar to those constructed by the irrigation engineers in India—upon the Godavery and Toombuddra works—and consists of a brick or stone wall 2 feet thick in front, having a batter of 1 in 1½; the rear wall being more perpendicular and composed of heavy blocks; all joints to be laid in cement; the space between the front and rear wall to be filled with river gravel, lime, and cement, in the proportion of one part cement, one part lime, and twelve parts gravel; the top should be narrowed to (say) 5 feet, the coping being of large blocks 5 feet long, and not less than 2 feet 6 inches wide, and 15 inches deep, tied together in the front with dowels, and at the back with iron clamps; sluices or gates being inserted near either end, to let the flood-water in or out as required. At the back of the weir or on the river side of it, a timber framing would have to be put in, composed of large logs laid in rows longitudinally and transversely upon each other, about 1 foot apart and three or four rows high, properly secured to the weir in order to form a cushion for the overflow-water and to prevent the earth from being washed away from the back of the weir. The height of the weir can only be determined by observing the highest known flood-level, and it should be at least 2 feet below it. I estimate the cost of constructing such weirs at £2 per cubic yard of their whole content, including the cost of the timber, &c. Putting it another way, the cost of impounding 100 million gallons of flood-water would average about £120. However surprising or startling these figures may be, they are not imaginary but real, and based, as I before said, upon actual survey. In many places I have no doubt the ground will be porous, and a large proportion, probably the whole of the water, may soak away, but I think it would take a considerable time to do so; and this, judging from the experience of Indian engineers, would not be likely to occur more than once, as they have found that the silt deposited from flood-waters acted as puddle and prevented the escape of the water. Assuming that it did escape, I am still of opinion that the value of extra grass grown around the water edge as it gradually subsided would be ample compensation for the cost of constructing the weir. This might in some instances be avoided by constructing another weir higher up the water channel, upon ground of a more retentive nature. The impounding of the flood-waters in the manner I propose would, I feel convinced, result in great benefit to many; and I would again urge the Government, stockowners, and all others interested, to give the proposal their earnest consideration. If I have omitted any information which it may be thought by any I could supply I will gladly do so, knowing that the securing of an ample supply of water means not simply convenience to a few people, but extension of settlement, utilization of land that would without it be utterly waste or nearly so, and an increase of wealth to the Colonies. Probably in no country in the world is the necessity for the due adjustment of those natural influences which produce fertility more fully exemplified than Australia. Only small portions of our continent possess what is usually known as a permanent supply of water for domestic and other purposes; and owing to the irregularities of the rainfall causing sometimes an excess and at other times a deficiency of moisture, the skill of the scientist and engineer is required to reduce those irregularities to a minimum.

In a short paper such as this full justice cannot be done to all the subjects I have touched upon, *i.e.* boring, well-sinking, dam-making, irrigation, and the construction of weirs. Each one should, I think, be treated separately and practically, and I hope to see some of the members do so. Water is the question of the future for the engineer in Australia.

There is no doubt that huge volumes of water descend upon the surface of the earth in Australia, and it is equally certain that no proper effort, or rather no effort at all, is made to preserve and turn to profitable uses that which Providence bestows upon us from year to year, and the engineer who can do so in the most economical and expeditious manner has a large field of usefulness before him. I have written this paper, hoping that by doing so I might be instrumental in inducing abler and more influential men to take up the subject, and draw the attention of the general public to its vital importance.

Summarized—I would strongly recommend—

1st.—The construction of underground puddle wall tanks where a subterranean supply cannot be obtained by boring or well-sinking. Under any circumstances, in new settlements, it is the most expeditious and economical method of securing a supply of water.

2nd.—Sink trial shafts where there is any probability of obtaining a supply by that means.

3rd.—Bore wherever the geological stratification is favourable. The small plant necessary can be had for about £60, and is therefore within the means of all. When the water is found, larger and better machinery can be obtained to increase the supply if necessary.

4th.—Establish local water-supply associations, with the view of their ultimately becoming "Water Trusts."

5th.—Introduce the best steam excavators for use in places where labour is scarce, and also the most improved boring machines, especially those that bore holes of large diameter; the quantity of water raised from a bore being in proportion to the size of the hole. The larger the bore the better the machine.

6th.—Construct weirs in approved situations near the confluence of the watercourses and creeks that feed, or are fed by, the large rivers at times of flood, so as to impound the waters at their highest flood-level. By constructing weirs as I propose, it is quite possible that a large quantity of the water might be utilized for irrigation purposes, probably not on an extensive scale, but of sufficient magnitude to enable us to determine what is best to grow and how to grow it. The experience thus gained would be of great value to the engineer and capitalist, should they contemplate undertaking any large irrigation works.

APPENDIX I.

APPENDIX I.

TANKS AND WELLS OF NEW SOUTH WALES, WATER SUPPLY AND IRRIGATION.

By A. Pepys Wood, Assistant Engineer, Roads and Bridges Department.

(Read before the Royal Society of New South Wales, 7 November, 1883.)

THE necessity for a liberal consideration of the question of water supply for the dry districts is of such rapidly increasing importance to those districts and to the Colony generally, that the time has arrived for active steps to be taken to obtain, by actual survey and observation, the data necessary to determine the best means to be adopted to conserve and distribute, in an economical and effective manner, that portion of our rainfall now carried off by our river systems and discharged into the ocean, conferring but little benefit on its course; though running through districts where the soil only requires its invigorating agency to produce in abundance any vegetable growth suited to the climate.

In framing this paper I have divided the subjects to be dealt with into two sections:—

I.—Water supply for stock routes. II.—Water supply for irrigation.

This course is advisable for two reasons: because the works to be dealt with, that have up to the present time been carried out by the Government, have been solely for the improvement of the stock routes; and because the important works necessary on these routes cannot generally be brought within the scope of any scheme having irrigation as its main object. Isolated cases may occur where watering-places could be provided for in this way, but as a rule it will be found that the supply for this purpose must be obtained from works complete in themselves, and constructed solely with a view to meet the requirements of stock traffic. This is a necessary consequence, inasmuch as stock routes are laid out to afford the best and shortest practicable connection between the terminal points, and without any reference to those differences of level that would prevent their being introduced into a general scheme of water supply. Cases might occur where points on such routes could be supplied from the irrigation channels, but such points might not be suited to the general division of the watering stages along that route.

I.—Water Supply for Stock Routes.

The stock routes of the Colony have an important bearing on pastoral industry, and deserve greater attention and expenditure in opening and improving them than they have hitherto received. Much may have been done, but very much more remains to be done before they can be considered efficient in facilitating the transmission of stock. They are the only avenues from the pastoral districts to the consumer, and from one pastoral district to another. Properly watered and managed they would be invaluable as affording a certain outlet to the markets, and also as a means of reducing to some extent the enormous losses that so often overtake the sheep-farmer during dry seasons; for at such times he would have the chance of removing some portion of his stock to more favoured localities for water and feed. It has unfortunately been the case that, even when improved, these routes have not been of as much service as is desirable. This is to be attributed to the long intervals separating many of the works that have been constructed for watering purposes, to the defective maintenance of many of those works, and to the defective conditions regulating grazing on the stock routes. When it has been determined to water any stock route, arrangements should be made to construct all the works necessary to complete the chain of communication, instead of constructing watering-places that, until that chain is complete, can only be rendered available at considerable loss and injury to travelling stock, or when the long intervals separating them are bridged by natural supply, at which time there is but little need for the water that has been artificially conserved. It is unfortunately often the case that many of these routes are practically closed, by want of feed, even when plenty of water is obtainable; and it is a matter of great importance that this evil should be remedied as far as is practically possible, and measures adopted to make the stock routes of sufficient width, to withdraw them from lease, and protect them from being grazed on by other than travelling stock.

In the year 1869, the Government first practically recognized the necessity for constructing watering stations on the stock roads, and a sum of £5,000 was then voted by Parliament for works on the Booligal and Wilcannia Road, and handed over to the Roads Department for expenditure. At that time no works of a similar nature had been carried out by the Government; and this, combined with an imperfect knowledge of the character of the country to be dealt with, led to a course of action being adopted which, however suitable it might have proved under different circumstances, required considerable modification to adapt it to the existing conditions of the question. The primary object was to obtain water by sinking, and with this view a boring plant, consisting of the ordinary rods and bits, was sent on to the ground, to test the nature and depth of the strata and the quality of the water to be procured.

The preliminary borings were commenced on the 1st October, at the Jumping Sandhill, about 30 miles north of Booligal, and were completed at Mount Monahra, about 120 miles from the same place, in January, 1870. The camp was then broken up, as there was no water on the "Death Track" between there and Wilcannia, a distance of 80 miles. To have carried out the works along that line would have necessitated a very heavy expenditure for haulage of water. In addition to this there were other reasons for suspending operations, chief of which were the difficulties experienced in obtaining and keeping efficient men, the high cost of labour, and the comparatively small depth to which the borings had to be carried. This latter cause had a most important bearing on the question, for it was found that the time occupied in shifting a large camp from one site to another, and in making the preparatory arrangements for boring, raised the cost of the work to a great extent. Had the drifts that were tested been deeper seated, the borings could have been carried out at a proportionately less cost per foot. The experience gained during the work was wanting at the outset; but, though it can now be seen where mistakes were made and unnecessary expenditure incurred, it must not be forgotten that the Department acted for the best and carried out the work under very considerable difficulties; further, that the experience gained, though perhaps rather costly, has been of much value and an eventual source of economy.

Looking back at those early efforts, there can be little doubt but that the better plan to have adopted would have been to have made a preliminary examination of the district in the first place, ascertaining how far it had been tested by works carried out by the Crown lessees, gaining information as to the depth and character of springs in existing wells, their positions, and the cost and character of works best adapted to the object in view. Sites could then have been determined, and tenders at once invited for sinking wells where there was a reasonable probability of obtaining suitable water. Where existing works proved that wells were not advisable, arrangements could have been made for works to conserve storm-waters; and in case of the surface features being unfavourable for tanks, the locality could have been tested for an underground supply by *letting* trial shafts, and possibly boring from the bottom of them for deeper seated springs, if considered necessary. Day labour would have been avoided in every possible way, for all the drawbacks connected with it in the settled districts were very much intensified in that back country. The works would then have been completed much sooner, and, as the cost of preliminary operations and of supervision would have been considerably reduced, there would have been a larger amount left for opening the road.

When the explorations were concluded, tenders were invited for the works determined on, and the following tanks and wells were at once put in hand, and completed in 1872:—

Well near the Willandra, at Mossgiel. Tank at Boonoonoo.
Well at Ivanhoe. Well at Mount Monahra.
Tank at Forty-eight-mile Swamp.

Since these were completed, further sums were voted, which have been expended as shown in the following list:—

Deniliquin to Hay—Pine Ridge—Dam.
" " —The Gums—Tank.
Hay to Booligal—One-tree—Tank.
" " —Quondong—Tank.
Booligal to Wilcannia—Jumping Sandhill—Well.
" " —Holy Box—Well.
" " —Twelve-mile Swamp—Tank.
" " —Thirty-five-mile Swamp—Tank.
Wilcannia to Hungerford—Copargo—Dam.
" " —Peri Sandhill—Tank.
" " —Nipper's Creek—Tank.
" " —Warramurtie—Tank.
" " —Gambolara—Tank.
Balranald to Ivanhoe—Box Creek—Tank.
" " —Youhl Plains—Tank.
" " —Till-Till—Tank.

Cobar

Cobar to Nyngen—Booroomugga—Tank.
" " —Muriel—Tank.
" " —Hermitage—Tank.
Cobar to Bourke—Cobar (Stock)—Tank.
" " —Cobar (Town)—Tank.
" " —Nullima—Tank.
" " —Tindary—Tank.
" " —Currawcena—Tank.
" " —Corilla—Tank.
" " —Two Water-holes—Tank.
Cobar to Louth—Cutty-gullaroo—Tank.
Bourke to Ford's Bridge—Tank.
Walgett to Bangett—Boro Water-holes—Tank.
" " —Lightning Ridge—Tank.
Barwon to Narran—Cumborah—Tank.
Narrabri to Moree—Galathera—Tank.
" " —Boggy Creek—Tank.
Wagga Wagga to Bland—Junee—Dam.
" " " —Wallace Town—Dam.
Wagga Wagga to Cootamundra—Hurley's—Dam.
Albury to Tocumwall—Major's Water-hole—Dam.

In 1882 a sum of £50,000 was granted for tanks and wells, and arrangements were made for its expenditure on the different stock routes recommended by the Mining Department. This amount was so much in excess of any previous grants, which had hitherto been of a desultory and intermittent character, that it was considered advisable to frame and adopt a more systematic course of action; and with this view, type drawings and specifications were prepared, embodying the results of the experience gained by the officers of the Department during the time they were engaged on this duty. This course was considered all the more necessary, as the large increase on previous grants indicated a recognition of the growing importance of the question; a recognition which will probably be followed by a development of present operations, so as to include the more important works connected with a general scheme of water supply for irrigating portions of the rich but arid districts of the Colony. A further sum of £53,800 was voted on this year's estimates, which with the amount granted last year, is being expended on tanks and wells as rapidly as possible; but great difficulties have been experienced in getting contracts for their construction taken up, the seasons having been exceptionally unfavourable for these operations. This has in many cases considerably increased the cost of the work: but it was considered advisable in the more urgent cases to carry out their construction at once, even at an increased outlay, rather than delay it to a more favourable season.

The works by which the stock routes have been supplied, or partially supplied, with water, may be divided into the following classes:—

1. Wells, 2. Tanks, 3. Dams,

and it will be advisable to deal with them in this order, describing the nature of the conditions surrounding each class, and the operations that have been and are now being carried out by the Government, in endeavouring to construct works that, while economical in detail, will at the same time ensure a permanent supply of water both for stock and human consumption.

1. Wells.

The conditions under which drift waters are obtained, and their important bearing on the settlement of the dry districts of this Colony, give this branch of the subject as great an interest as any with which we have to deal. This interest is, in a measure, due to the difficulties surrounding a satisfactory solution of the origin of, and the varying conditions under which these waters are discovered; but still more is it due to the fact that this source of supply, when the quality of the water is suitable for stock, is at once the most certain and economical means of meeting the great want which settlers in that country have to contend against. So far our experience of the question may be considered as confined to the more shallow-seated and unfortunately non-artesian drifts; but it is a matter for congratulation that money has been voted by Parliament, and operations commenced for testing the great west and north-west country for a deeper seated and hoped for artesian supply. Should the predictions regarding the existence of such a supply prove well founded, and the water that may be discovered prove suitable for stock, or still further, for irrigation purposes, it will be almost impossible to estimate the increased facilities that will be offered to settlement, or to assess the increased value of that portion of our territory.

Whether the predictions are likely to be realized appears to be a question that can only be satisfactorily settled by the *boring-rods*. Theorizing, though much has been indulged in, has so few well ascertained data on which to build hopes of an ever-flowing, inexhaustible supply, and is opposed by so many ascertained facts proving the uncertainties connected with the discovery of water in the shallower drifts, that we may, if hopeful, wisely be doubtful, till all room for doubt is disposed of by actual test.

Many reasons have been advanced by the advocates of an artesian supply to support their views; amongst others, the mud springs between the Darling and the Paroo, and the height to which water has risen in some of the deeper wells north of the Darling. These are *facts*, but whether they are entitled to the wide interpretation given to them—whether they indicate *general* and not merely *local conditions*—remains to be proved.

The Government Astronomer, in his "Rain and River Observations" for 1880 and 1881, has published some very interesting reports bearing on this question; but it may possibly be found that the deductions he has drawn may be capable of very considerable modifications when the conditions connected with the rainfall on the Darling basin are investigated. In his report for 1880 he writes:—"Since the rain measures of 1880 and the river measures for the same period are more complete than they have ever been before, it will be worth while to test one by the other. I have before endeavoured to prove that the water passing down the Darling in an average year is only a very small portion of the rainfall, and is in fact very much less than must be available for that purpose, after every allowance that can be made for evaporation and vegetation. For 1880 we have the means of testing this question by observations more complete than any which have previously been taken over the best part of the watershed of the Darling, that is the western slopes of the Main Range, where, from the abundance of rivers and creeks, it is obvious that the rain-water readily runs off the soil. There are forty-five rain stations, and the mean rainfall derived from these is 20·74 inches; the area included is about 110,000 square miles; all the drainage from this country passes Bourke, in the river Darling, and at this point a daily record of the height of the river is kept, and the mean result shows that the river has averaged throughout the year 6′ 8″ above the summer level. The width of the river at Bourke is 180 feet, and the velocity when in flood is rather less than one mile per hour. A few figures, which I need not give here, suffice to prove that ¼ of an inch of rain over the watershed, or $\frac{1}{70}$ part only of the rainfall, represents all the water that passed Bourke during the whole year. When full allowance is made for the power of evaporation in a dry year, and for all other circumstances which might prevent the rain-waters reaching the rivers, it is certain that a very much greater proportion than $\frac{1}{70}$ becomes running water. In such country as that under discussion, common experience would give ⅓ of the rainfall as the available water, but for the sake of being on the safe side, we will assume that only $\frac{1}{70}$ of the rainfall becomes running water, and it still represents a quantity sufficient to supply eight rivers like the Darling for the whole year.

"It therefore seems impossible to doubt that an unlimited supply of water passes away underground, more in fact than would suffice to make the whole of the western districts a well-watered country, and all that is wanted to make this supply available is a judicious use of the *boring-rod*."

In his report for 1881 Mr. Russell further states:—"The evidence is conclusive that the annual supply from rain finding its way into this great natural storehouse is perfectly inexhaustible; it is also certain that as much must find its way out as in, every year, under natural conditions, and the few wells that have been sunk prove that the outlet is so situated that the water is under pressure in the reservoir, and will rise up to or above the surface when wells are sunk into it."

Mr. Russell speaks with no uncertain voice; and as his views have an important bearing on the question of water supply for these districts, both as regards wells and surface conservation, they are well worth our serious consideration.

The rainfall over the Darling basin above Bourke having been determined with more or less accuracy during 1879, 1880, and 1881, and the mean level of the river at Bourke having been also ascertained for the same years, we are enabled to make a rough comparison of the fall and discharge.

1879.—Mean rainfall...	33·24 inches.	Mean river level...	29·08 feet.
1880. " " ...	20·47 "	" " ...	6·66 "
1881. " " ..	18·88 "	" " ..	0·75 "

The proportional difference between the rainfall and the river discharge for these years is so great that it is necessary to try and discover a reason for the discrepancies, and then, if possible, show the connection this may have with the general question—that the enormous proportion of the rainfall, mentioned by Mr. Russell, disappears underground and feeds our water-bearing drifts.

In

In 1880 and 1881 it will be seen that the rainfall was very near the same, yet in the latter year the discharge, which, if there were no disturbing elements, ought to correspond, was only ⅛ of what it was in 1880. Again, in 1879, the rainfall, which was 80 per cent. in excess of 1881, was accompanied by a discharge thirty-eight times as great. There must be some reasons for these differences, and as they have an important bearing on the estimated loss by a deep soakage it will be well to consider how they can be accounted for.

In the first place the mean rainfall must be considered, and by referring to the rain maps there appears to be a possibility that this has been over-estimated. These maps show that there are a greater proportional number of observing stations on the eastern side of the watershed than there are on the levels occupying the central and more westerly sections; and as the rainfall is greater on the eastern side, any preponderance of observing stations there must give an excess of the true mean, unless the area composed by each station is made an element in the calculation.

The discharge of the Darling at Bourke also appears to have been incorrectly estimated, and to be less than the actual discharge. The estimate is based on the velocity of the river in its normal state, that is, on the velocity when there are no disturbing influences, as when the river is in flood and full for a considerable distance above and below the point of observation. This velocity is estimated at nearly one mile an hour, and, with the cross section of the river waters at their mean level, forms the basis on which the discharge is calculated. If we examine the river curves at Bourke, we find that the floods are in many cases of short duration, forming a series of waves succeeding one another at longer or shorter intervals. This being the case, the normal velocity can scarcely be considered a satisfactory factor, as it should have an increased value when the river is at its higher levels and the water coming down in a wave. This is borne out by Mr. Russell's statement that a flood in November, 1881, travelled from Bourke to Wilcannia in three days—this gives a velocity of *seven* miles an hour.

The proportion of rainfall likely to become running water must to a great extent be dependent on the features of the watershed. On the eastern side, which is bounded by the coast range, the proportion must be much greater than it is on the levels, where but a very small percentage finds its way into the main channels; and when the rainfall is greatest on the eastern side of the shed, we must expect to find that a larger proportional quantity finds its way into the river than when contrary conditions prevail. *This was decidedly marked in* 1879, when there was such a great discrepancy between the *supposed* mean rainfall and the river discharge, as compared with the two other years quoted. The conditions under which the rainfall occurs must also have an important influence; the heaviness of the fall, that is, the quantity measured by the time; the intervals separating different falls; and the state of the ground at the time of the fall, whether dried and cracked by summer suns and capable of absorbing largely; or with a close saturated surface capable of throwing off the maximum proportion of the rainfall. Account must also be taken of the enormous bodies of water brought down by the rivers that are intercepted and diverted in filling lagoons, warrambools, swamps, and lakes; and that in heavy floods, are thrown back over the level country for scores of miles, and largely retained there when the floods in the rivers recede; retained in shallow creek beds and swamps, when the evaporation is enormous.

These causes—over-estimated rainfall—under-estimated discharge—*enormous* evaporation on the levels which form the largest proportion of the area of the basin—the loss in filling secondary channels, &c.—and the surface soakage—all taken together, may probably materially modify the results arrived at by Mr. Russell.

It may be advanced that the "surface soakage" just alluded to is the great source of loss, that, percolating to the lower drift beds, is their main supply; but the soakage referred to is of a very different character, and that it takes place to an enormous extent is known to all who are acquainted with the country under consideration. The dry, parched soil, seamed with cracks and fissures, hungrily drinks in the water falling on it, but the impermeable clay beds prevent its descent to any great depth, and the burning summer heats and dry thirsty winds rapidly evaporate the water lying on the surface of the ground, dry the soil, and the moisture carried away from the surface layers is replaced from below by capillary attraction, and exposed to evaporation under conditions which reduce it to vapour much more rapidly than it can take place from a water surface.

That there may be places where large quantities of water find its way underground, to supply the lower drift beds, cannot be positively denied; but that such wholesale percolation takes place generally is very improbable; and if the conditions advanced fail to support the view that this enormous loss by percolation does not take place, then it would be interesting to ask how this large body of water is disposed of; and how far our knowledge of the conditions under which water-bearing drifts are discovered in that country sustains or disproves the assumption that they are so lavishly supplied from the surface.

The geological bearings of the case I leave for those more conversant with that science than I am, but *en passant*, it would be interesting to ask this question—Where is the subterranean outlet for the enormous proportion of the rainfall that has been and is being absorbed on the Darling watershed above Bourke, if Mr. Russell's assumption is correct? Is not its escape to the ocean debarred by the older rocks that crop up through the alluvial deposits, and that extend from the dividing range between the Lachlan and Darling near Gilgunnia, through Cobar, and running northerly with some *surface* breaks, cross the Darling on to the Warrigall? It appears very probable that these older formations must cut off the alluvial deposits to the east of this line from those to the west, and therefore from the ocean, and that consequently the assumed percolation on the Darling basin should be stored locally, and that the increasing storage should show itself in an increasing rise in well waters in that district or in surface springs. But this is not the case. Again, assuming that this rock barrier does *not* exist, and that the drift beds are continuous to the ocean, we are met by as great a difficulty in reconciling such a discharge to the conditions of the case. A thousand miles of drift must oppose an insurmountable obstacle to a free discharge of water; and assuming that it has an existence, there should be a very perceptible rise in the levels of well waters, more particularly towards the eastern side of the shed and during wet seasons; this is however not the case.

Apart from these views, there are several other considerations that have an important bearing on the case, and that are difficult to reconcile with Mr. Russell's views. Those who have conducted boring operations or have sunk shafts in that country, or those who have watched and noted the work carried out by others, must be aware that in the alluvial country it is very rarely that water is missed at the ordinary depths of the shallower-seated drifts underlying those districts; they must also be aware that there are thick beds of stiff impermeable clays passed through before water is obtained; that water when struck rises to a greater or lesser extent, and then retains that level, independent of either long continued dry or wet seasons. The conclusions to be drawn from these works, which at intervals are pretty well scattered over that country, is that the water-bearing drifts and underlying clays are general. This being the case, how can the extensive soakage assumed to exist in accounting for the small discharge of the Darling as compared with the rainfall on its basin, be accepted as reasonable? Again, if instead of admitting general loss by soakage, we admit that it may occur on a large scale in certain localities, we have to face the same difficulty in reconciling a varying head of supply with a constant level in the wells tapping these drifts. If it is said that this uniformity is due to the fixed level of the discharge of the drifts beds it does not relieve us from the difficulty, for whether the level of the discharge is regulated by the ocean level or whether that discharge takes place before reaching it, there must be such an enormous length of drift to be travelled by the water before obtaining an outlet that the back pressure would be virtually equivalent to a seal. Again, if this constant feeding and escape of water is going on now it must have been going on for ages past, and it therefore appears strange that, as it had been found that brackish surface drifts improve by being worked, that all the brackish elements have not long since been washed out of the deeper drifts by the constant assumed flow through them. The objections now raised naturally point to an old supply for these drift beds—a supply which has remained stagnant and locked up for ages—a supply that is exhaustible with time and pumping plant, and which is so inconsistent with the views held by those who have fondly dreamed of perpetual artesian flow, that it is not at all likely to be kindly received by them. They have, however, the pleasure of knowing that their theories are opposed only by theory, and this shows the necessity that exists for obtaining, by systematic effort, data connected with this question; until this is done, all efforts to arrive at a satisfactory solution of the apparent inconsistencies which are constantly cropping up will be futile. Mr. P. K. Abbott collected many facts relating to wells in the Liverpool Plains district, and, in a very interesting paper read before this Society, in November, 1880, gives much valuable information bearing on the question in that locality. The observations commenced by this gentleman should be followed up in other parts of the Colony, the positions of all works of this character being determined and marked on a map; the level of the drift containing the water and the level to which that rises in the bore or shaft being shown in each case, and the levels reduced to a uniform datum. The strength of supply and quality of the water, with the influence of long continued droughts or wet seasons should also be noted. In the course of time, when the level above alluded to had been determined over a large area of country, it might be possible, *if there is any under-ground flow*, to plot a curve giving a value to the head of supply and the back pressure in these drifts. The general information, when a sufficient amount of it has been collected, might enable the courses of the drift channels to be traced, and save much loss of time and capital in uselessly sinking upon salt-water beds.

In

In the works constructed by the Government for reaching, lifting, storing, and distributing underground waters, the shafts are slabbed right through, and divided into two compartments, each 2 feet 6 inches square, by a brattice extending from the top to the bottom of the shaft. The lifting appliances consist of a whim and gearing working two self-acting buckets, which discharge into a timber-framed, iron-lined service tank communicating with the troughing for watering the stock. In carrying out these works, great care has to be taken to have the slabbing thoroughly fitted, and clay well puddled into all spaces at the back of same. Care must also be taken to have the shaft carried down truly and having the runners properly fixed, as the smooth working of the buckets is dependent on attention to these points; while all roughness or jarring in their travel very soon loosens the slabbing and increases the cost of maintenance. Some of the water-bearing drifts are very troublesome and difficult to deal with, and in such cases if the water has a considerable rise, with a strong supply, it will often be found advisable not to sink to the drift, but to stop some few feet above it and then put down a carefully tubed bore to tap the water. Boring can also be advantageously resorted to in some cases, to avoid the necessity of puddling back water of bad quality—often a difficult and expensive operation—when it is underlaid by good water having a sufficient rise to give the required supply in the shaft sunk to within a few feet of the former.

When these works were just initiated several modifications of the type adopted were considered by the Department, and amongst these were:—

1. Brick-steining in lieu of slabbing. The objections to this proposal were based chiefly on the increased cost, and on the difficulty, which in some cases amounted to a practical impossibility, of obtaining labour and material for the purpose. A modification of this proposal was also considered, to stein the lower portion of the well in this way to protect the water from the effects of the timber slabbing, but it was not adopted, as a composite system would have been awkward on account of the change in the shape and dimensions of the shaft that would have been necessary. The cost and difficulties before alluded to were also at the time prohibitory.

2. The employment of masonry and of puddle for service tanks was also considered, but at the time framed timber lined with galvanized iron was adopted, as being more certain and better adapted for the purpose than either of the others. Stone is often far more difficult to procure than timber, and lime or cement becomes very expensive on account of the cost of carriage. Masonry service tanks are now being constructed in a few cases where timber is very scarce and stone procurable close to the work. Earthen puddle tanks require great care in their construction and in their maintenance; they should never be allowed to run dry, as if they do they soon begin to lose water; but where they are attached to wells where a constant supply of water is available to keep them full, they would, if attended to, prove more economical than either the framed or masonry tanks; and as their use would allow of a large storage at a small cost, wells having a weak but steady supply could in many cases be utilized. Iron-framed, buckled plate tanks are now being tried, and should prove more lasting and economical than any other type yet adopted.

3. The use of pumps in lieu of the primitive whim was also considered and abandoned, as at the time it would have been difficult to effect necessary repairs, and this might have caused great loss to stock dependent on watering-places where the pumping gear was out of order. The conditions surrounding these works have however altered so much since they were initiated that it is now well worth while considering whether water cannot be raised in a more economical manner than by the use of the whim, which under favourable conditions fails to utilize more than 50 per cent. of the horse power. The application of this power to pumping gear would give better results, and would not only be more economical in itself, but would very considerably lessen the cost of the shaft; for when double buckets were dispensed with the size could be very much reduced, lessening the outlay on both sinking and slabbing; the latter too would not be subjected to the same strains as with buckets working either on runners or with bumpers; strains, that in bad ground, especially running drifts, often lead to great expense for repairs and, in some cases, total abandonment of the work. The use of the horse as a motive agent, even when applied to improved gear, should however be avoided as much as possible, as in bad seasons there are elements of uncertainty attached to it, even as there are to its more economical rival wind. This agent has up to the present time not been tried by the Government on these works, and for the same reason that prevented it, years ago, adopting improved pumping gear; but the time has arrived when the primitive machinery of the past can be abandoned and more perfect appliances adopted, and in future works of this class, where the conditions are favourable, windmills and pumps will be provided instead of the whims now used for the purpose. Objections have been urged against the use of windmills for these works, on the ground that the wind might fail at the very time when a lot of travelling stock required water. This objection is perfectly valid; but the evil can be met by constructing larger service tanks, which, as there would always be water in them, might be made of puddled clay walls and bottom, which would without any increased cost provide a much larger surface storage to meet any sudden demand.

Before concluding these remarks on wells, it may be advisable to draw attention to the use that could in many cases be made of drainage shafts in localities in the dry districts where drifts are known to exist within from 10 to 20 feet of the surface, are also known to have a limited area and to be influenced by the local rainfall. In such cases the power of storage could be very much increased by sinking shafts to tap these drifts in places where the surface features favoured the collection of either standing or running water, which would then discharge down these shafts and be rapidly stored under favourable conditions as to temperature and evaporation, and at a depth from which it could be economically raised to the surface as required.

2. Tanks.

Most of the works for supplying the stock routes with water come under this head; and before describing the different types of tanks that have from time to time been adopted, it may be as well to give a short sketch of the conditions under which surface waters should be collected and conserved, and under which stock using these works should be supplied with water. In selecting a site for a tank the main points to be attended to are—that the area of the watershed will suffice, under the conditions of rainfall, to fill the tank and keep up the supply necessary to meet loss by soakage and evaporation and the demands made by stock traffic; that the nature of the surface of the shed allows of a sufficient proportion of the rainfall being available for storage, this being materially assisted by a proper system of gathering drains, by the fall of the country towards the tank, and by the consolidation of the surface by stock or otherwise; that the soil in which the tank is to be excavated is of a retentive nature; and in estimating this latter condition it must be borne in mind that many tanks which when first constructed lose water subsequently become thoroughly water-tight, this result being due to the deposit of clayey silt brought off the catchment by the rains. Advantage should if possible be taken of the features of the locality to provide for a storage of water above the surface of the ground. This course, when it can be carried out, materially lessens the cost of the work, as a much smaller amount of excavation will suffice than where the whole of the storage is below the natural service. This super-surface conservation may be effected either by gravitation or by pumping over the embankment enclosing the excavation. In the former case, which is of course the more preferable, there must be rising ground near the tank site, with a sufficient catchment above the level of the embankment to allow of the enclosed area of the tank being either wholly filled, or filled to a sufficient extent to warrant the expense of fluming. In the latter case the features, though not suitable for an over-bank discharge, must allow of a collection of water at the tank site which, after filling it to the same level through an inlet pipe, can then be pumped over the embankment into the tank.

When tanks are constructed in watercourses, the plan adopted by the Department is to make an embankment below the excavation; and in cases where the channel is shallow and the fall of the bed considerable, this dam is carried above the level of the creek banks, and flanking embankments carried on the same level as dam are continued up each side of the creek until they cut the natural surface of the ground. In other cases, where the fall of the bed is inconsiderable, a dam is constructed both above and below the excavation, and these if raised above the level of the creek banks are joined by lateral embankments; an inlet pipe is laid under the upper dam, which allows water to gravitate into the excavation and enclosed space until it reaches the level of the water outside; a valve is then closed, and if necessary the outside water is pumped over the embankment into the reservoir. This plan, while giving a greater depth of water, at the same time shuts off the tank supply from that in the shallow reach above it, and considerably reduces the loss by evaporation and soakage. In all works of this character great care must always be taken to provide an adequate by-wash, and wherever it is possible, the work should be located to allow of a natural channel being used for this purpose.

The system to be adopted in watering stock at these works involves two questions of great importance; that of the economical use of the water; and the preservation of its purity as far as is practically possible when it is gathered off what must be to a great extent a camping ground. It may be laid down as a broad principle that, to attain these ends, stock must not be allowed to water *in* the reservoir; for the amount of water carried away by sheep in their fleeces, the amount of silt carried by them into the tank, and the pollution of the water by all kinds of stock when drinking are all so great that no arguments are necessary to support this view; and it was fully recognized by the Department when the first works were constructed.

constructed. These tanks provided for independent watering, but subsequently many departures were made from the original design. These modifications, which will be presently described, were made to reduce the cost and to simplify the details as much as possible; the latter course being rendered all the more necessary on account of the heavy outlay that had to be incurred in repairing the older works which had been very inefficiently maintained.

The first departure made from the original design was to introduce a separate tank with flattish slopes for stock to water in; this being connected with the main tank by a pipe with a valve, so that the inflow of water to the drinking slopes could be regulated to the demand. The advantages claimed for this design are—economy in first cost, economy in maintenance, and simplicity of detail. The disadvantages, which overbalance the benefits, are thus set forth by Mr. Bruce, the Chief Inspector of Stock (report for 1880):—"That a great deal of the water, as now supplied from them, is liable to be polluted and carried away by the stock wading into it, especially by sheep; that they are liable to be crushed and injured in crowding down into the drinking-tank; and that the waste of water by evaporation is greatly increased by its being allowed to run into and stand in the drinking-tank." Mr. Bruce might have added too, that the inlet pipe from the main tank to the drinking-tank is very liable to be silted up and rendered inoperative.

On the Cobar to Nyngen Road the tanks are simple open excavations, in which all stock water direct. This is undoubtedly the simplest, and, in first cost, the cheapest form, but it is open to the objections previously urged as to waste and pollution of water, the latter too in an aggravated form which is very marked when the water is low. These tanks were constructed to meet the urgent wants of the Cobar township and mine, and to secure the trade from that important district for the Sydney market.

The last type of tank to be noticed is that adopted in the Bourke district, which, with a separate drinking slope, has an *open* communication with the main reservoir, through a box drain. This plan nullifies any advantages that might be claimed for the separate drinking-tank system as already described, and aggravates all the objections to it, reducing it in fact to a level with the open single excavations on the Cobar to Nyngen Road, with the added disadvantages, that the first cost—for equal contents—is greater, and the exposed areas for soakage and evaporation much increased.

The experience gained in carrying out these works has led to the conclusion that the system first adopted is that which, considering the greater facilities that now exist for obtaining skilled labour, and for transporting and repairing the necessary plant, should be adopted in all future works; and type drawings have been prepared which, while showing some alterations in detail, embody the same principles that were followed in the first works of this class carried out by the Department.

The main alteration in the details of construction is the employment of pumping gear in lieu of the M'Comas water lift. This avoids the necessity for a lot of submerged timber-work, which, in addition to being very expensive, is always an element of weakness; it also lessens much of the annoyance and inconvenience due to silting, which chokes the M'Comas lift but is avoided with our pumping appliances, by a floating suction pipe. Another alteration is the construction of a service tank to supply the troughing instead of connecting it direct with the pump. This gives stock a much steadier supply when they are watering, and provides a reserve to meet any sudden demand when the pumps are under repair.

The use of pumps for increasing the storage by lifting water over the embankments, in cases where it collects outside the works, has been considered and approved, but the power to be employed has not been determined. In all cases where the conditions are favourable windmills should be employed; and in forming an opinion on this point it must be remembered that, as they are slower and more uncertain in their action than steam, they can only be advantageously used for feeding the main tank when there is a considerable collection of water outside the embankments. When this is not the case, more rapid pumping will be necessary, and then steam should be employed if fuel is procurable within a reasonable distance. Pumping appliances should be erected at each work, and used for filling the service tank, in addition to pumping water over the embankments for storage. This course is preferable to having a portable engine and centrifugal doing duty at the tanks along one or more lines; for in many instances fuel would be too distant from the sites to be economically used; the stages would be too long, and the delay as between one tank and another would mean the loss of the outside water, which if it collected in sufficient quantities to admit of such delay, should be pumped into the tank by wind-power.

Windmills, though they have not received much attention, and have been but little used in those districts, are destined to be extensively employed in lifting water both for stock and irrigation. When it is considered that there are very few days in the year during which good work could not be obtained from a well constructed mill—that the first cost is comparatively small—and that the after cost for work done is confined to the expenses for maintenance—it seems very strange that attempts have not been more generally made to utilize this power. When its value has been practically tested and the results are presented in a tangible form, there is little doubt but that it will be extensively used by all who are interested in the adoption of a cheap means of raising water, whether from wells or tanks, whether for stock watering or irrigation purposes.

Great difficulties are often experienced in letting these works, more particularly during dry seasons, when the want of water and feed within a reasonable distance of the tank site render it absolutely impossible to carry them out; and in other cases, somewhat less unfavourable, has increased the cost of excavation from 30 to 40 per cent. above the price for which it could have been done in good seasons. This is the necessary consequence of employing animal power in ploughing and scooping—though this system has very much reduced the cost of excavating and has almost entirely superseded manual labour. Attention has consequently been directed to steam power, and Fowler's ploughing and scooping plant has been successfully used for some time in South Australia. More recently the Messrs. Edols at Burrawang purchased and worked a similar plant on their property, where I saw it in operation in May last. The following extracts from my report to the Department explain, from my point of view, the relative advantages of steam and animal power under varying conditions:—

"This plant consists of two 16-h.p. traction engines, with horizontal winding drums for working a double three-furrow balance plough and an earth scoop. There is also an 8-h.p. traction engine for drawing water and firewood, and for assisting the main plant when travelling from one side to another. The cost of this on the station was about £5,000.

"The advantages claimed for this machine are—

"1. That it is independent of the seasons, and able to work under conditions that would prohibit the use of bullocks or horses.

"2. That it is much quicker and more economical than animal power.

"3. That it is easily transported from one locality to another, and through country where bullocks would die for want of water and grass.

"In practice I think it will be found that these advantages are not fully realized, and that there are very important modifying influences to be considered.

"1. Though it can work under conditions that would prohibit the use of bullocks or horses, it is not fully independent of the seasons, inasmuch as it consumes about 1,800 gallons of water per diem, which is equivalent to what would be consumed by about 120 bullocks. Herbage or grass is of course not needed, and so far this plant is independent and is in a position to do work where animal power could not be applied; but firewood and water are as necessary for the engines as are grass and water for bullocks; and where these requisites are scarce, and have to be hauled from any considerable distance, the limit for the application of this machinery is very soon reached. In favourable country for running the traction engine I consider, from what I saw at Burrawang, that 20 miles would be about the limiting distance for haulage of wood and water; but in unfavourable country, that is, where the ground was loose and sandy or where it was boggy, the limiting distance would be much reduced, for in such ground the traction engine is unable to work, or works under such difficulties that its normal efficiency would be very much lessened.

"2. The claim for superior speed and economy can only be partially sustained. In bad seasons, when animal power could not be applied on account of there being no feed, and in places where firewood and water were within a reasonable distance by a sound track, the steam plant commands the situation; but in good seasons the work could be more rapidly carried out by bullock plants if the same capital was invested in them, but not at the same price, though even on this score there is not much to be advanced in favour of the steam plant, as will be seen by reference to the following figures showing the cost of excavations by both systems:—

"Cost of steam plant £5,000

Weekly

Weekly expenses—				
1 engineer and manager	@ 80/ =	£4	0	0
3 drivers	@ 30/ =	4	10	0
1 steersman	@ 25/ =	1	15	0
1 scoopman	@ 30/ =	1	10	0
1 clearer (for rope)	@ 25/ =	1	5	0
2 woodcutters	@ 20/ =	2	0	0
1 cook	@ 20/ =	1	0	0
10 rations	@ 12/ =	6	0	0
Oil, &c.		0	10	0
Interest @ 8 per cent.		8	0	0
Depreciation @ 12 per cent.		12	0	0
Total		£42	0	0

"The work done in a week is equivalent to about 2,500 cubic yards, which makes the cost 4d. per cubic yard.

"This estimate of cost is based on the supposition that there are no stoppages, and that there is no delay between one tank and another; but, as a matter of fact, there are many stoppages and much delay in transporting plant. This latter element of loss increases to a great extent in sandy country or in wet seasons, when the bullock plant is most favourably circumstanced. Taking these disturbing elements into consideration, we must fix the price of the work done at a much higher rate. I estimate that only thirty-four weeks in each year can be relied on for work, the balance being required to cover the various unavoidable delays. This affects the estimate of cost to a considerable extent; for with a plant of this character, requiring trained men to work it, no reduction can be made in the weekly expenses during the time it is idle; consequently we have fifty-two weeks' wages, &c., at £42, representing thirty-four weeks' work at 2,500 cubic yards a week, or 85,000 cubic yards, costing £2,184, being at the rate of 6d. per cubic yard.

"Cost of bullock plant				£1,300
Weekly expenses—				
1 manager	@ 60/ =	£3	0	0
5 bullock-drivers	@ 30/ =	7	10	0
2 ploughmen	@ 30/ =	3	0	0
5 scoopmen	@ 30/ =	7	10	0
1 tailer	@ 25/ =	1	5	0
1 cook	@ 30/ =	1	10	0
15 rations	@ 12/ =	9	0	0
Interest @ 8 per cent.		2	0	0
Depreciation @ 10 per cent.		2	10	0
Total		£37	5	0

"A strong plant like this could excavate about 1,500 cubic yards in a week, which would cost 6d. per cubic yard.

"This estimate, like that for the steam plant, requires modification, as the bullocks could not, for various reasons, be constantly worked. Estimating the same loss of time, which taking the average run of the seasons is I think, equitable, and we have—

34 weeks' work	@ £37 5 0 =	£1,266	10	0
18 weeks' idle time	@ £18 0 0 =	324	0	0
		£1,590	10	0

"This amount represents thirty-four weeks at 1,500 cubic yards a week, or 51,000 cubic yards, and the cost per yard is about 7¼d.

"From this it will be seen that the same amount of capital invested in bullock plant would give a much larger output while at work, but at an increased cost of 1½d. per cubic yard. Could the seasons be relied on, there is little doubt that animal power would be preferable to this form of steam plant, as the extra cost by bullocks is fairly balanced by the risk of breaking down, &c., which in the out of the way places where this machinery would be employed, would entail great loss of time and money, and very soon cover the small margin of difference in favour of steam.

"When, during long continued droughts, it is impossible to employ animal power, and when water and fuel are available for steam, then this plant comes to the front and offers the only practical means of tank excavation."

Another excavating machine, invented by Mr. Waugh, is now at work near Sydney; and though it does not avoid the necessity for employing horses and drays to remove the material, promises to very greatly reduce the cost of "getting." It has the advantage of being less cumbersome than the ploughing and scooping machinery, is much less costly, but is far more limited in its application. The patentee is perfecting the machine, which, being constructed on a new principle, has naturally exhibited some defects. When these are remedied, it promises to be a valuable addition to the resources at our command for reducing the cost of excavation either in tanks or canals.

II.—Water Supply for Irrigation.

There are few questions of such importance, few questions with which the future prosperity of this Colony is so intimately interwoven as that of irrigation; and considering the extent to which works of this character will promote settlement and mitigate the uncertainties that now attend both pastoral and agricultural occupation, it seems strange that no steps have been taken to ascertain to what extent and at what cost the rainfall of this Colony can be conserved and distributed over the waterless areas of our western sheds, where a rich soil, now lying fallow, only waits its invigorating influence to yield returns, that, with the climate we possess, would convert it into a mine of wealth. Surveys that will require years to complete, and that are essentially necessary to assist in framing a comprehensive scheme, are not even commenced, and the time must be far distant when we shall be able to lay claim to having taken the first great step towards developing the wonderful resources of our lands. It cannot be said that attention has not been drawn to the advantages to be derived from such works, for seventeen years ago, when giving evidence before the Board appointed to inquire into the Moama and Deniliquin railway scheme, Mr. W. C. Bennett, Commissioner and Chief Engineer for Roads, drew attention to the yearly waste of water brought down by our western rivers, and the practicability of employing it for irrigation purposes. The Commissioners appointed to inquire into a water supply for Sydney and suburbs, in their report thus allude to the subject:—"Although our commission limits us to an inquiry into the supply of Sydney and suburbs, we have not been unmindful of the great desirability of obtaining such a plentiful command of water as would permit of its free use in irrigation; not only in the immediate neighbourhood of Sydney, but also over some considerable portion of the county of Cumberland. We feel convinced that this question of irrigation ought no longer to be neglected. Our comparatively dry climate, coupled with the very unequal and uneven distribution of rainfall, point imperatively to the necessity for making provision for storing up the superabundance of rain that occasionally falls, that it may afterwards be dispersed to the thirsty soil as required, and thus secure fertility and plenty in all seasons." Time after time have letters and leading articles appeared in the public journals drawing attention to what has been done and gained by such works in other countries, and showing the necessity of action if we intend to avail ourselves of the latent wealth at our feet; but in even plainer language and with practical force has Nature herself indicated what water can do in the dry districts, and how readily, if conserved and at our disposal, it can be distributed over the face of the country. In proof of this I instance the spread of the flood-waters of the Murrumbidgee, Lachlan, and Darling, in 1871; the net work of connections between the Bogan, the Macquarie, and the Castlereagh Rivers, in the counties of Clyde, Leichhardt, Gregory, &c.; the water circulation in North Gipps, which, with many other instances, point in no unmeaning manner to the facilities offered by the natural features of the country for distributing the supply brought down by our rivers, and for pouring living streams of water over the thirsty plains. Yet notwithstanding all this, season after season as it rolls by shows us our rivers, fed from the higher lands by the greater rainfall, by melting snows and by springs, carrying

carrying the life-blood of the country through the very districts where its fertilizing agency is a necessity to success, to discharge it to waste in the ocean; while those who have eyes to see, and *must* see the incalculable advantages that would accrue from utilizing it, look on and abuse Nature rather than exert the powers they possess and assist her to assist them.

The conditions surrounding this problem in this country are widely different to those which had to be dealt with in India and Southern Europe; there a teeming population made it necessary that increased and certain returns should be obtained from the soil, and there as soon as the facilities for obtaining water were afforded they were immediately taken advantage of, and thus, both by direct and indirect returns, enterprise in this direction was encouraged. In the former country, though much remains to be done, it is almost impossible to over-estimate the blessings that irrigation works have conferred on the people, improving both physical and moral tone, and to a great extent mitigating the evils that in a densely populated country attend the failure of the crops that form the great staple of life. In this country, instead of having a large population settled on the soil requiring the assistance offered by such works to meet their wants, we have an immense territory possessing a soil capable of growing any products suited to the climate, which is now little better than a huge sheep-walk, but which is capable of being converted into great agricultural districts capable of supporting thousands where now it is difficult to count tens. This paucity of population has been urged as an argument against such works being undertaken, the inference being that population must precede irrigation. This means that irrigation will never be carried out on the great western plains, for I maintain that in the Riverina districts irrigation works must precede settlement, that is, settlement on any but a pastoral basis. To those acquainted with these districts this must be obvious, for without water agriculture is impossible, and except in certain confined and favoured localities, it is impossible for irrigation to be applied to any agricultural holding by ordinary private enterprise. The pastoral tenant—the sheep farmer—can provide all the water he requires for his flocks by local conservation in tanks and wells; but the large quantities of water required for crops cannot be locally conserved in the flat country, while to obtain it from distant sources means an expenditure of capital far beyond the abilities of any agriculturist, and far in excess of any returns that could possibly obtain from individual holdings. Maintaining these views, I fail to see how the hopes entertained as to settlement on a large scale, following on the liberal railway policy pursued in these districts, can possibly be realized; I fail to see how, unless water is at our command, the lines constructed, being constructed, and those proposed, more particularly the latter, can ever carry much besides pastoral produce. Whether railways through these districts will pay under such conditions remains to be proved; but that they would do so were a population settled on the country, actively engaged in cultivating the soil, does not admit of a doubt, any more than does the fact that, taken in connection with a water supply, they would have an important bearing on settlement in such improved districts, by the facilities they would give for distributing produce grown in those districts.

Believing as I do, that in those districts the construction of the main channels for distributing water must precede settlement, it follows, that for some time after their construction they will have a more important bearing on pastoral than on agricultural occupation; and though, even from this narrowed view of the question, they will be of immense importance, it cannot be expected that they will prove remunerative until they are utilized for the more comprehensive objects for which they were constructed. The advantages to be derived from such works by the sheep-farmer are manifold, and in themselves well worth consideration. Prominent amongst these are—the direct facilities that would be afforded for watering stock by giving new frontages along the arterial channels, while the benefits from this source could be much increased by cutting distributing channels to feed tanks off the main lines, and by turning surplus waters into the many natural hollows existing in those districts. A great saving of feed would result from this, by allowing of a more equable distribution of stock and by lessening the distances they would have to travel between feed and water. Such channels would also aid in keeping communication open in all seasons, and thus allow, should occasion arise, of the transfer of stock from less to more favoured districts, and materially lessen the enormous losses to which pastoralists are liable during droughts. Nor must it be forgotten that these channels would in their districts afford the means of mitigating to a greater or lesser extent the evils attending droughts, by the facilities they would give for growing artificial crops, which being stored during good seasons would materially assist in meeting the wants of stock during bad seasons.

One of the first steps to be taken, or that, judging by the benefits that are likely to be derived from a comparatively small expenditure, should be taken, is to assist Nature where she has defined the course of the waters during flood-times, and improve the *régime* of the overflow channels from our rivers, such as the Merowie, Middle Billabong, and Willandra from the Lachlan; the numerous creeks leading from the Macquarie to the Bogan; the various channels forming a natural system of distribution in North Gipps; and many other cases, all of which are capable of being made of immense service to their respective districts. These watercourses should be straightened and improved, so as to admit of an inflow at a lower flood-level, and to allow of a larger body of water being carried down them during the comparatively short periods when the rivers afford a gravitation supply: these periods should also be lengthened by the construction of weirs. Branch channels should be cut to divert flood-waters from the rivers and overflows into the numerous lakes, swamps, and natural depressions found in those districts, which could in many cases be utilized, not only for the benefit of the adjoining lands, but also as reservoirs to make good the loss from various causes in the overflows, &c. The advisability of carrying out this latter work would of course be greatly dependent on the advantages to be derived as compared with the cost of cutting the feeders; but as these could be utilized along their courses, the distances of these natural reservoirs from the point of diversion becomes a matter of less importance. Sluices would necessarily be required to regulate the waters and to prevent a back flow when the rivers fell. Private efforts have been made in some few instances to attain these ends; inlets have been cut from the rivers to these secondary channels, which, generally speaking, are more imperfectly defined where they leave the rivers than they are further on in their course; but most of these efforts have failed to fully realize the expectations of the promoters—failed because, though admitting the river waters at a lower level, the channels below the inlet improvements were left unaltered, and only capable of carrying the water forward at the velocity due to their natural *régime*, this velocity being very small, on account of the sinuous course of these creeks through a comparatively level district giving a much lesser fall than that of the country on the general direction of flow. Much could be done in this direction by judiciously planned works—done, too, with a very moderate outlay; and though these improvements would have a limited application to irrigation, they would yet assist in that direction and would be of immense benefit to the pastoral industry, and would greatly increase the value of the Crown Lands and the rents that ought to be derived from them; and when, later on, they were connected with a more perfect scheme, they would be as valuable to the agriculturist as in their earlier stages they were to the sheep-farmer.

The important bearing of these channels, &c., on the water supply for the districts they intersect points to the urgent necessity that exists for taking prompt measures to reserve from sale all lands adjacent to them, that, under normal conditions, can only be utilized for grazing, but that would be valuable for agricultural purposes when provided with a certain water supply. This course should also be adopted under similar conditions of settlement on all belts of country where, without survey, there is sufficient reason to think they can be brought within the scope of any general scheme of irrigation. This course will be necessary to prevent the improved areas, or the areas proposed for improvement, being alienated for purely pastoral purposes, and to ensure that the Colony generally shall reap the full advantage of the increased value of these lands—an increased value that should be credited to these works, and which, while recouping the country for a considerable proportion of the outlay, would at the same time practically prohibit these areas being devoted purely to grazing. The increased cost of such land would also have the effect of making the holder more rapidly develop its capabilities, and would ensure every advantage being taken of the irrigation works, without which the cultivator could not rely upon a return for his labour and capital, and without which these works could not be expected to prove remunerative.

In considering this question from a general point of view, it must be borne in mind that as the features of the country to be dealt with vary, so may there be room for an equal variation in the nature of the works best adapted for the object to be attained; and it will therefore be advisable to divide the subject into two main branches, dealing separately with irrigation derived from local sources, and with that derived from our great rivers; not forgetting that many cases may arise where the supply obtained from the former could be largely aided by the latter, and *vice versa*.

The country to be dealt with consists in the west and south-west of extensive plains, broken here and there by sand-hills and low ranges, and with a small fall in the direction of drainage, but nearly level transversely to such lines, except where watercourses and ridges are intersected. To the eastward the ranges become more frequent, and of greater magnitude, gradually culminating in the coast range which divides the eastern and western watersheds. The rivers and their earlier tributaries have a considerable fall in their upper courses, but this gradually diminishes as they run westerly, till in the plain country it does not much exceed 4 inches in the mile, but as the bends give a river length roughly estimated as being three times greater than that of a direct line, the fall of the country would be about 12 inches per mile.

The

The rainfall over these districts varies very much, being dependent to a great extent on the features of the country and on position in regard to the main coast range, where the fall is heaviest. From this range there is, with some slight local irregularities, a marked decrease of the rainfall as we advance westwards. The nature of the rainfall is not only spasmodic in its annual amount, but is equally fitfully distributed over each year. This has an important bearing on the proportion that is converted into running water and that can be conserved for future use, as also on the loss by evaporation; this must be greatest on the low-lying western plains, where the ground has a high temperature and the winds are very dry and act very continuously. The loss from this cause must attain its maximum when the annual fall is so distributed that the minimum of running water is formed, when, consequently, there is no concentration of rainfall off large areas to reduce the evaporation surface, and to further lessen loss by the difference in the rate of evaporation off a water surface as compared with that off the soil. In such cases I can readily understand that, were the supply kept up under equally favourable conditions for the whole year, we would have fully 20 feet to record as the result. But unfortunately we have no data on this point, any more than we have as to the proportion of this evaporation that may be given back by condensation in other form than that of rain. But although these data are not at our command, and as it is consequently impossible to arrive at definite conclusions as to the exact number of inches, we must take the measure of evaporation in different localities; and although we admit that where light recurrent rains fall on a baked and heated ground surface, and are exposed to hot and thirsty winds, the evaporation must be enormous, I yet think we are justified in taking more hopeful views as to the possibilities of irrigation than has been done by those writers who have *lately* made a bugbear of the evaporation question, and have tried to prove that it must render any irrigation scheme impracticable. It cannot be denied that in the eastern and hill districts of this watershed the rainfall is greatest, and evaporation much less than on the plains; that the incline of the country favours a rapid concentration of rainfall, giving water surfaces of limited area for evaporative agencies to act on. In these districts the rainfall must be impounded for after distribution through artificial channels; and while so concentrated, the loss by evaporation need not trouble us here much more than it does in other dry countries, save that we have not as copious and constant a supply to draw on as other countries have had for their irrigation schemes; but when concentration ends, and the water is discharged over the surface to be irrigated, then the loss from this cause will be heavy; but it still remains to be proved whether a 2-inch watering, even admitting the rapid loss, will not produce as great a vegetable growth with the forcing climate of our plains as the same amount of water where the heat and evaporation are less, and where the water remains longer in the soil. Judging by the wonderful effects produced by even half an inch of rainfall in the same country, it appears probable that the rapid loss by evaporation is in a measure made up to us by the equally rapid growth of vegetation. Should this view be incorrect, is the loss through evaporation so *much* in excess of what it is in other dry countries that we should at once despair? I think not. The loss from a water surface in Bombay has been estimated at about 6 ft. per annum; in this Colony, at Bourke, Mr. H. C. Russell estimates the evaporation at about 7 ft. Presumably the evaporation off the soil, as compared with that off water, will bear the same proportion to one another in both countries, in which case our position is very little more unfavourable than is that of India, where irrigation has been carried out on a large and most successful scale.

From the foregoing it will be seen that there are two classes of country for us to deal with: that on the middle levels, where the rainfall is, taking an average of years, fairly abundant, where the evaporation is not very great, and where the slope of the country is sufficiently marked to convert a large proportion of the rainfall into running water, which under normal conditions is rapidly carried away by creeks and rivers. The other class is on the level lowlands, where there is a minimum of rainfall, a maximum of evaporation, and so little incline, that under ordinary conditions of rainfall but little running water is formed.

Local conservation of rainfall for irrigation purposes can only be adopted in the hill country, where the natural features offer facilities for storage. The works for this purpose, which in India are called tanks, have been largely used in that country from time immemorial, and great benefits have been and are still being derived from improvements of this class. In the Madras Presidency, in 1853, there were, according to Captn. R. Baird Smith, no less than 43,000 tanks in use, and 10,000 more which had been allowed to get out of repair and were of no service. In forming an opinion of the amount of work involved in the construction of these reservoirs, it must be remembered that the work "*tank*" has a much broader significance in India than it has in this country, where they are little else than excavations, few of which contain more than 20,000 cubic yards; *there*, tanks are large reservoirs conserving enormous bodies of comparatively shallow water, which is impounded by embankments. The Ponairy tank in Trinchinopoli covers an area of about 80 square miles, the embankments being 30 miles in length; while the Veranum tank has an area of 35 square miles, and embankments 12 miles long. Similar works could be constructed in this Colony, and a large proportion of the rainfall locally conserved and distributed. Dams could be thrown across valleys and basins, and, where the drainage from the watersheds naturally feeding these reservoirs was insufficient, channels could be cut to bring an extra supply from some adjacent shed, or, in many instances, could be made to divert the flood-waters from neighbouring creeks or rivers. By such means as these the evil effects of our spasmodic rainfall could be mitigated in the improved districts, and isolated areas of rich land made permanently reproductive and independent of the seasons in localities which could not be brought within the scope of a general scheme, either on account of the levels being unfavourable, or on account of much valueless land having to be traversed by the canals before the district to be irrigated could be reached. In such cases the cost of bringing water from a distance might be prohibitory, and then the only courses open would be to take advantage of local supply, to trust to the seasons, or to abandon the ground for agricultural purposes. The first of these alternatives can only be successfully followed when the rainfall and catchment area are sufficient to provide the necessary supply, and when the natural features offer facilities for storage and distribution at a cost that will allow of the water being made commercially reproductive; the second alternative of trusting to the seasons seems to be born of the happy-go-lucky style of farming so general in this country, and which, unless in particularly favoured districts, or in favourable seasons, is as general in its failure as in its adoption. The last is often the natural sequence of the second alternative, and in far too many cases for the interest of the community has this been the result of undertaking agriculture under conditions that without artificial regulation are too unfavourable to allow of success; the consequence being that these lands, rich though they may be, revert to the Crown, or are absorbed into some large pastoral estate, the selector and would-be farmer having wasted not only his small capital but some years of labour which could have been more beneficially employed in other channels. Amongst the many advantages to be derived from *local* conservation, is the fact that there need be no such delay in providing the necessary supply as would be the case if the lands to be dealt with had to wait until they could be brought within the scope of a general scheme; and this advantage is increased by the fact that such works could be undertaken by district Boards, whereas the larger and more comprehensive scheme, being national in its aspect, would have to be dealt with by the central authorities. The important bearing of such local works on the welfare of the country is very forcibly shown by the concluding remarks in Captain Smith's report on irrigation in the Madras Provinces. He says: "I cannot close my report without reverting for a moment to the field of improvement presented by the Presidency of Madras in the single department of irrigation. In all parts of India, profit to the State and the people follows, as certainly as effect follows cause, the provision of an abundant supply of water for agricultural purposes, but in Madras the results go far beyond the general average. The staple of agriculture in the irrigated districts being rice, the want of water brings with it abject poverty and discontent, its abundance wealth and contentment. Every acre that is newly watered passes at once from the revenue rate of dry, to that of wet cultivation, guaranteeing to the Government an immediate return, paid with far greater ease to the cultivator of the land than the lower tax leviable before. The return is immediate, and its amount great. I have almost hesitated in adopting the data given by the Madras Commissioners of Public Works, so extravagantly large do they appear; but they are statements founded on official returns, open to verification, and unlikely to be seriously in error. When these show returns varying from 77 to a maximum of 259 per cent. on the original cost of the works, it is inconceivable that fields parallelled only, if parallelled at all, by those of Australia and California, can be left much longer unwrought."

This description, however true it may have been in its application to the districts alluded to at the time it was written, is scarcely parallel with the conditions surrounding the question in this Colony; but after making every allowance for sparse population, high priced labour, and distant markets, there is much still left to excite hope and sustain the belief that the time has arrived when irrigation works should be initiated; and that in the years that must elapse in carrying them into complete effect, settlement will be borne steadily forward on the living streams distributed through the thirsty land; successful settlement developing the latent wealth of the Colony and ensuring a grand future of peace and prosperity.

The local conservation we have been considering, though it must have a great influence on the advancement of agriculture, is secondary its extent and importance to the supply offered by our river systems, on which we will have to depend for irrigation in the low country, or for providing water for any comprehensive scheme; and sooner or later active steps will have to be taken to draw these waters into our service, and to utilize them so that they will lessen the loss and misery attending droughts in the pastoral districts, increase the stock-carrying capacity of the country, and develop the extraordinary but latent

latent agricultural resources of districts where an unrivalled soil and climate will yield abundant returns to reward our enterprise. To attain these desirable ends water and population are necessary. The former we possess, and it only needs capital and skill to divert it into channels where it will be at our command, a potent power in the advancement of the Colony, instead of being carried wastefully to the ocean, a practical satire on our plaints and prayers: the latter—population—must, as far as the dry districts are concerned, follow, not precede, such works; and there is little doubt that when water is obtainable for irrigation, agricultural settlement will certainly follow, more particularly as the preliminary cost of preparing the surface will be much less than what it is in many other countries, both on account of its natural evenness and on account of the small quantity of timber to be dealt with.

The few attempts at irrigation that have been made in the Riverine district have been conducted under great disadvantages, as the water has been pumped from a low level, and the cost consequently increased to a very great extent. Notwithstanding this great drawback the results have been very satisfactory, and point in a most unmistakable manner to the benefits that must be derived from the construction of works that will deliver the required supply by gravitation. The following extracts from a letter kindly written by a gentleman who is intimately connected with one of the largest pastoral properties on the Murrumbidgee, need little comment, except to draw attention to the fact that the water was raised by steam power, and that the cost of irrigation on which the writer's opinions are based was much in excess of what it would have been under a properly carried out scheme delivering the water by gravitation, and also much in excess of what it would have been with steam pumping, had there been weirs to raise the water level and reduce the lift. This gentleman writes as follows:—"Some years ago I ploughed up about 10 acres near a lagoon on this station and sowed a portion in lucerne, a portion in prairie grass, a portion in maize, and a portion in oats.

"The soil, although rich enough, is rather stiff and clayey, and it was very imperfectly broken up when the seeds were sown; the consequence being that the crops came up very unevenly, but all the plants that did come up grew very luxuriantly.

"I irrigated the patch by pumping the water by means of a 12-inch centrifugal pump, and a 12-horse power engine from the lagoon into a raised channel carried round the higher side of the land; from which channel the water was allowed to overflow, by making breaches at intervals in the bank, spreading itself about until all the land was saturated. The ground is almost a dead level, so that there was little difficulty in distributing the water over the surface.

"I watered it about five times during the summer months, giving it on each occasion a soaking which I should think equal to 2 inches of rain or thereabouts.

"The maize crop grew well to a height of 8 or 10 feet, and the cobs of corn were of good size, but I kept no record of the quantity gathered. The lucerne and prairie grass were fed down with sheep, and the oat crop, a very fine one, was cut down for hay. The lucerne is still growing and thrives well. The prairie grass died out last summer, when I did not irrigate it.

"The primary object of my experiment was attained in satisfying me that crops of all ordinary kinds suited to the climate can be grown in great abundance in this district by means of irrigation, but I could not pretend to give anything like an accurate estimate of the cost per acre of laying down and watering, or to speak with anything like authority as to the profitableness or otherwise of the work.

"I am inclined to think that ordinary agricultural products of a compact and easily transportable kind, such as flour, would be more cheaply purchased elsewhere, and brought down by rail, than grown here under irrigation, but that irrigation might be profitably used for producing hay, which is bulky, and consequently expensive of carriage; or for raising potatoes or roots, which are perishable, or green stuff to feed valuable stock on in time of drought.

"I think also that wine-growing might be profitably carried on under irrigation, as vines thrive very vigorously here when liberally watered, and produce grapes of great richness and flavour.

"One thing I may mention which may appear somewhat incredible to people who have seen the Murrumbidgee River only in time of flood, viz., that I think the supply of water in the summer-time would sometimes be found inadequate to very extensive irrigating operations.

"The stream is frequently, from January to March, so shallow that a horse may ford it without wetting his knees, and of no great width; and from the quantity of water I have myself pumped up with one engine and pump for irrigating and sheep-washing purposes, I feel sure that if 500 or 1,000 other people were each withdrawing a similar quantity of water from the river the stream would be found insufficient.

"This drawback could of course be obviated by the construction of weirs to impound large quantities of water in the channel, and prevent it from running to waste; but this work would probably be found too expensive to be undertaken until the country becomes very much more thickly peopled than it is likely to be for many years yet."

From the foregoing extracts it will be seen that the writer only tried and only formed an opinion on the profitableness of irrigation from the results obtained with the everyday agricultural products of the Colony; but, great as would be the advantages of extending the cultivation of such products into the dry districts, they would be insignificant when compared with the returns that would be obtained from the more profitable cultivation of plants that are more particularly adapted to the Riverine climate, such as indigo, madder, chardon, hemp, limes, olives, &c.

The concluding paragraphs of the letter have an important bearing on the question; and, before proceeding further, it may be well to consider the nature of the rivers from which our supply must be drawn, and the conditions under which water can be stored and diverted for distribution. As has been previously remarked, the fall of the rivers, which is very slight in the lowlands, increases considerably as we trace them towards their sources. Another feature is, that where they have the greater fall they run through deep and comparatively narrow valleys, bounded by ranges of considerable abruptness, and generally of a rocky, barren character; that when the fall is slight there they run in deep-seated beds through a plain country, over which the waters spread for very considerable distances during floods. The quantity of water brought down by these rains is, on account of the spasmodic nature of the rainfall, very variable; some seasons give a full river for months at a time, while there are equally long periods during which the flow is insignificant. To meet these variations and to equalize the supply that must be provided for irrigation, impounding works are the first necessity, and there is little room for doubt that this must be carried out, not only in the comparatively level reaches of the rivers, but more particularly in the middle and upper courses of the main channels and their tributaries. Many of those who have interested themselves in the question consider that weirs in the lower courses of these rivers, impounding water on the frontages of the lands to be irrigated, will meet the requirements of the case; but a little consideration will show that any such limited supply would be quite inadequate for any broad irrigation scheme, and that the cost of the works to carry such a plan into effect would be out of proportion to the benefits derivable from it.

The quantity of water annually required may be estimated at 12 inches, being six waterings of 2 inches each. This amounts to 43,560 cubic feet per acre. Assuming the river to have an average width of 150 feet, and that the depth maintained was 20 feet, this would give a storage of 15,840,000 cubic feet per mile of river channel, and would provide for the irrigation of 360 acres, or a strip of land on each side of the river about a quarter of a mile in width. It may be said that no account has been taken of the occasional supply brought down, and which would refill the ponds; but as there *are* seasons when no such supply could be relied on, and as irrigation to be successful must be certain, I have left this out in my estimate. The expense of constructing weirs and, on our navigable rivers, locks, for maintaining traffic, would be out of all proportion to the advantages derived, for even then the water would have to be raised by steam or wind power. The construction of weirs in the alluvial country characterizing the lower reaches of the western rivers of this Colony would be a very costly undertaking, on account of the difficulties that would be experienced in protecting such works from scour. Exceptional cases might arise where rocky bars would be found crossing the rivers, on which such works could be securely founded, but these cases would be few and far between, and can almost be neglected in considering the subject. It may possibly be urged, as against the objections now raised, that the expense of constructing such works could not be charged in its entirety to the irrigation funds, inasmuch as with locks in connection with the weirs permanent navigation would be established, and this should be debited with a portion of the outlay. This, however, cuts both ways, as it reduces the quantity of water at disposal for irrigation by the depth that would have to be maintained for navigation; but, apart from this, it is worth consideration whether, if such improvements are ever considered advisable, lateral canals would not be found preferable to improving the existing channels, with their tortuous courses; with the large supply of water required to provide for their unnecessary length and width; and with the constant difficulty of maintaining such works in flood-time. Taking all these points into consideration, such a system for irrigation supply must be discarded, though, *in connection* with the impounding operations that should be carried out in the upper reaches, weirs might be of modified use on the lower levels for assisting in the diversion and storage of water.

The great object to be attained is to provide a steady, certain supply that can be distributed by gravitation, and to compass this a sufficient body of water must be stored in the upper courses of the main rivers and their tributaries to provide

a supply during the season of least rainfall, when the natural flow would be insufficient; and, having made this provision, to construct canals to receive and carry into the dry districts the water so stored. The upper and middle, or upper-middle courses of the rivers to be dealt with, are far more favourably circumstanced for economical storage and diversion works than they are on the levels; for the fall, though not too great to allow of moderate impounding works throwing back the water to a great distance, is yet sufficient to allow of the water being readily diverted from the natural channels into artificial canals excavated for the purpose. The valleys through which these rivers pass are in many places very much contracted, the waters running through narrow gorges which open out above into large basins. These sites offer favourable opportunities for constructing weirs, the foundations on these sections of our rivers being of a sound character, and no difficulties likely to arise from the flanking action of scour. Enormous bodies of water could be stored in such places without any disproportionate expense being incurred, and in some cases with a very small outlay. The tributaries to these rivers would have to be similarly dealt with, means being provided in each case to allow the impounded waters to be discharged as required, so that any surplus over what would be needed for merely local wants could be passed down to supply the lower ponds where the water was being drawn off by the main canals, and those ponds still lower down where, either by steam or wind, water was being raised for irrigation along the rivers.

The preceding remarks are necessarily of a merely general character, for the data at our command are of such a very meagre nature that it is a matter of impossibilty to formulate any scheme. Before this can be done, careful observations must be made of the discharge of our rivers at different points, and extensive and accurate surveys prepared, showing the quantity of water we can command and the cost of the works for conserving and distributing it. Until this is done, any views on this question must be vague and ill-defined; but we know enough of the conditions under which irrigation will have to be carried out in this country, and under which it has been carried out in other countries, to enable us to take a practical view of the question as a whole; enough to protect us from being carried away by the mad enthusiasm which pictures the whole of the dry country converted into a garden of Eden, and at the same time protect us from the baneful workings of those who handle our rainfall and evaporation as weapons of attack with which to rout those who earnestly desire to see this country benefited by a wise use of those blessings we have too long neglected. For the present we must wait, wait patiently but not without hope, for the first steps to be made to carry out the necessary surveys in connection with, at least, one of our rivers, and to obtain other necessary data on which to frame some tangible, practical scheme.

APPENDIX J 1.

Notes on Drilling and Boring Artesian Wells, as practised in the United States of America; by Mr. C. W. Darley, M. Inst., C.E., Principal Assistant Engineer, Harbours and Rivers Department.

During my recent visit to America I availed myself of the opportunity, thus afforded, of inspecting the various systems which have been adopted there for sinking artesian well bores; and, at the request of the Honorable the Colonial Secretary, I now have the honor to submit a report upon what I saw, together with particulars and sketches of the appliances in use. I trust that my notes may be of some practical benefit and assistance to those who are likely to be engaged in searching for water at great depths in these Colonies.

In some respects I fear the information I have obtained may appear scant and insufficient; but it must be borne in mind that the time at my disposal was somewhat limited, and the distances to be travelled over, in order to see the various boring operations in progress, were immense.

The boring, as hereinafter described, being in most cases carried on by contractors who have portions of their apparatus covered by patents, some difficulty was found in obtaining information on many important points of practical detail, the contractors frequently being reticent, and suspicious as to the object of my interrogations; on the other hand, manufacturers and vendors of apparatus were most willing to furnish me with abundant information, but in all cases this had to be received *cum grano salis*, as the information imparted seldom went beyond praise of their particular apparatus, and but rarely were any really useful and practical notes to be obtained from such sources.

The States where I found most boring operations in progress were, California (where wells are being sunk for both water and oil) Colorado, New York, and Pennsylvania; in the latter State, so far as I am aware, oil and gas wells only have been sunk.

The process of sinking holes through rock, as is necessary in nearly all instances where great depths have to be reached, either for water or oil, is usually termed "drilling," and "boring" when alluvium or gravel and sand beds only have to be passed through; but in these latter cases drill gear is sometimes used to advantage, as will be hereinafter explained,—the immediate difference between the two methods being that drilling is usually done with only a limited length (about 40 feet) of iron rods, which are worked suspended from a stout hawser, while boring is carried on with continuous bars, either wood or iron, in about 25 feet lengths.

In California I found a great number of wells being bored all through the San Joaquin Valley, which embraces a large district, some 280 miles in length north and south, and some 70 or 80 miles wide, lying south of Stockton, and between the foot of the Sierra Nevada on the east and the coast range on the west. This district in its natural state, owing to the extreme dryness of the climate, the rainfall only averaging from 8 inches to 10 inches per annum, is a barren desert; the soil is of a light loamy or sandy nature, only covered in places here and there with patches or tufts of a wiry grass, and so far as I could ascertain is quite useless without irrigation. Within the last five years this land has been obtainable at about a dollar (4s. 2d.) per acre; its value however when properly irrigated has long been known. Some years ago a large tract was brought under cultivation, with the assistance of water supplied by canal and flume companies, who constructed flumes from the head waters of the King's River, and entered into contracts to supply landowners with a certain quantity of water per acre per annum, at a fixed rent, the supply being guaranteed to the users by deed for a fixed period, usually 99 years; the right thus acquired is transferable with the land. Owing to the limited quantity of water, however, but a comparatively small district has been thus improved. Knowing how valuable the land became with the assistance of water, induced the settlers to endeavour to obtain a supply by artesian wells, which latter have now proved so successful and reliable that land throughout the valley is worth on an average at least $50 to $60 (£10 to £12) per acre, some land suitable for fruit-growing realizing over $100=£20, per acre.

The water is usually found at depths varying from 350 to 600 feet, in a bed of sand which is overlaid by beds of impervious clay, and clay and gravel mixed, the upper 40 to 80 feet throughout the valley being light, loamy, and alluvial deposit.

In the gravel beds, immediately beneath the upper alluvial deposit, water is frequently met with, but it is usually limited in quantity, indifferent in quality, and seldom or indeed never rises to the surface; on small farms and homesteads however it is not despised, being generally sought for and obtained by the ordinary drive, or Abyssinian tube wells; but as the water must then be pumped, it cannot be economically used for irrigation purposes, although in some districts where water has not been obtained from deep artesian wells, hundreds of the drive wells have been sunk and the water raised by windmills.

When sinking artesian wells it is necessary to stop back this upper water, for two reasons; first, to prevent it contaminating the purer supply from below; and secondly, which is the more important, to prevent the rising water being lost or absorbed in the upper pervious measures. This led to the bores being lined throughout with iron tubes or casings, which is an imperative necessity, for in some instances, where the ground was found strong enough to stand without caving, unlined bores were tried, but they were found never to flow till lined.

The absence of watertight lining will probably be found the reason why water has not risen to the surface more frequently than it has done in the numerous well shafts sunk in Australia, where it is well known that a porous stratum, frequently containing brackish water, is usually found at depths of from 40 to 90 feet below the surface, the brackish water in some cases having been stopped back sufficiently to allow the sinking to continue till fresh water was reached; the latter then rose in the well to within some 30 to 60 feet of the surface, but no higher. There can be little doubt that in such cases the lower water found an escape through the pervious measures; had a watertight lining been used, it is quite possible that many of these wells would now have been flowing ones, *i.e.*, the water would have risen above the surface.

I wish, however, to guard myself from being misunderstood on this point, as I do not desire to raise false hopes by conveying the idea that any method of treating artesian bores in water-bearing measures will obtain flowing wells, as this wholly depends on the situation of the bore geologically; to obtain this, the water must be stored in the earth and have communication

communication with an under stream or water-bearing strata, leading from hills situated higher than the ground surface at the bore. The hill source may be a great distance away; still, if the water-bearing-strata are overlain with measures of impervious clay, upon these measures being pierced the water will rise to the surface, unless, as before mentioned, it finds an escape through upper pervious measures.

In the case of the San Joaquin Valley, already referred to, the abundant supply found there of course comes from the neighbouring Sierra Nevada, where the winter snow is stored and given out throughout the spring and summer months, just when the water is most needed, the mountains thus acting as a natural reservoir for conserving the water.

The business of sinking artesian wells has become such a large one in the States that a great many contractors have turned their attention to the subject, nearly all of whom have introduced some special methods and appliances of their own for carrying on the work. Frequently the contractors take the work on the "No cure no pay" system, that is, if they do not find a flowing well they are not paid; but of course this is only done in districts known to contain artesian water, it being merely a matter of going sufficiently deep to reach it. Under this system, should any failure occur, either through carelessness or accident, which may render it necessary to abandon the bore, and perhaps a considerable length of the casing within it, the loss falls on the contractors. So far as I could ascertain, the cost of the work is very much the same with one apparatus as with another; but as there are varying circumstances under which each kind may have a special advantage, I will describe three kinds of apparatus which will fairly represent the different types of machines mostly in use:—

1st. The ordinary boring apparatus, with a variety of special tools used in connection therewith.
2nd. The hydraulic well-borer.
3rd. The ordinary drilling apparatus, as specially suited for artesian wells where the depth rarely has to exceed 600 feet.

Hand-boring Apparatus.

The ordinary boring apparatus consists of a wood or iron derrick (see plate I), with a sheave on top, about 30 feet over the ground; beside the single leg is placed a crab-winch carrying a sufficient length of 1½" iron or steel wire rope; the winch usually has two driving pinions, one for working by hand, the second for working by horse-gear, for running up the rope quickly, more especially when working with the sand-pumps. The boring bit (varieties of which are shown on plate II, figures 7, 8, 9, 11) is attached to the rods, which are usually made up in 25 feet lengths, either wood or iron, the iron ones being made of 1½" gas pipe, with screwed pin and box ends welded on; these however would be found too heavy on the boring tool if wholly used, so it is the practice to use some rods of pine, 4" x 4" (see plate I, fig. 2), which owing to their buoyancy in the water with which the bore is charged, help to balance the weight of the iron rods. The top or working rod is usually made of 1½" square iron, on which a capstan spanner travels and works—two men are sufficient for giving the necessary circular motion to the rods. It will be seen that in this process much delay must necessarily be incurred in drawing the rods every time the auger is filled, which happens about every fourth or fifth foot sunk. The rods on each such occasion have to be raised, unscrewed, and laid aside one by one, the reverse operations when lowering taking an equal time. Notwithstanding this delay, I found that the 7-inch wells were bored to a depth of 400 feet and lined with casing at an average rate of nearly 25 feet per day—the first 100 feet being performed much quicker, and of course the last 100 feet proportionately slower. When adding on or sinking casing, the rods need not be withdrawn, but left standing on the bottom or suspended from the expanding plug (see plate II, fig. 3), the top or capstan length only being removed. The auger bits are made in a variety of patterns, some altogether with closed sides for working in sandy or very loose ground, others made with one side quite open like a carpenter's shell auger and termed the pod auger (see plate II, fig. 7). This pattern is found to work very well in stiff clay, and is readily emptied. When beds of fine sand are met with, then the sand or sludge pump, as shown at plate V, fig. 15, must be used; this is usually lowered by a small line and jumped when at the bottom till the sludge or sand is worked up loose, when it readily fills, and upon being drawn up quickly the ball valve prevents the sludge from escaping; when emptied it is again lowered, and the process repeated till the bore is clear ready for the rods to be lowered and the boring resumed.

Besides the common sand-pump last referred to, which can only be filled by jumping it on the bottom, there are others made with a sucker valve rod, which, when the pump reaches the bottom, is worked up and down with a light line from the surface; this pumps the barrel full of the sand or silt, at the same time discharging the water above the plunger. Another form of pump for clearing out bores is shown on plate V, fig. 12. The great advantage attending this somewhat more expensive form of pump is the facility with which it can be emptied by simply knocking up the sliding sleeve on top, when the tube opens longitudinally with a scissors' joint, instantly releasing its contents.

Care must be taken in boring not to let the excavation get too far in advance of the casing, or the sides may cave in, and cause the bore to become out of line. Should this occur it may be found impossible to force down the casing, and consequently render it necessary to abandon the bore.

I found that the invariable practice is to start the bore 7 inches diameter, and if possible carry it the same size all the way down, but in most cases the friction against the casing becomes too great to admit of its being sunk more than 300 feet of this size, and then a 6-inch casing is put inside and the hole carried on with the smaller diameter to the required depth. In a few cases I found 8-inch and 7-inch holes being sunk, but these sizes are exceptional, 7-inch and 6-inch being generally found large enough. When a hole containing two sizes of casing, in this way, is finished, the inner or smaller casing is usually cut off by special tools a little above the bottom of the large casing, and the upper length withdrawn to be used again. A tool suitable for this purpose is shown on plate II, fig. 6.

As it is necessary that the auger should bore as near as possible to the inside diameter of the casing, it is necessary to have a set of augers for each size, *i.e.*, about a 6¾-inch auger for the 7-inch casing, and 5¾-inch for the 6-inch casing.

When about to start a bore, as soon as the derrick is set up, a hole should be dug under the centre some 6 to 8 feet deep, and the first length of casing set up vertically in the centre; the earth is then filled in round it again and well rammed, thus forming a guide and insuring a fair start for the boring tools.

A horse-power machine is usually used in conjunction with this boring apparatus, for the purpose of operating the winch rapidly when drawing the rods and working the sand-pump; the most convenient method of conveying the motion to the winch is with friction wheels applied with a cam motion; in this case the horse can be kept constantly moving when drawing rods; the attendant need only place his foot on a lever to throw the friction pinion in contact with the winch wheel, and thus wind up the rods 25 feet at a time, or as may be necessary. The circular motion for working the rods is, however, given to them by two men walking round with the capstan spanner as before mentioned.

Hydraulic Boring Apparatus.

This apparatus (see plate III, fig. 7) is worked very much on the same principle as the diamond drill, the action of which is, I believe, pretty well understood now in this country. The rods are formed in the usual 25-feet lengths of strong gas or lap-welded iron piping, 2½-inch or 2¾-inch internal diameter, with screwed wrought iron spigots and socket connections at their ends (see plate III, fig. 1); the lower length carries the cutter, the best form of which is shown at plate III, fig. 2.

A strong stream of water is pumped continuously down the rods, through a swivel cap at the top, shown at fig. 4. The rods are driven at a speed of about 80 to 100 revolutions per minute, and the débris from the cutter is carried up the annular space between the rods and the casing, with the escaping water, and discharged at the surface. As the casing is rarely less than 7 inches internal diameter, it is necessary to thicken up the rods, encasing them in wooden lagging to reduce the area between the rods and casing, and thus increase the velocity of the discharge water, to enable it to carry up the débris as fast as the cutter excavates it. The rods, joint, and lagging are shown at figure I.

The arrangement of derrick used is shown on plate III, fig. 7. To secure the proper speed and power requisite to manipulate this machinery a steam-engine is necessary. The pump for forcing the water down the boring bar may be attached to the engine, and the water supplied to the pipe head through a flexible rubber hose. This machine is capable of doing very rapid work. I witnessed about 20 feet being sunk in about half an hour, the depth of the bore at the time being some 524 feet below the surface; this included pressing down the casing at the same time, but of course not the building and riveting up of the casing, this part of the work occupying more time than the actual boring.

The contractor had arrived on the ground with his plant to start the bore just 11¾ working days before the date of my visit, and, as above mentioned, the bore was then over 500 feet deep, cased all the way; necessarily some time was lost at first in setting up the derrick and engine, excavating a tank for water supply, &c., so that the actual boring and casing must have been carried on at a rate considerably over 50 feet per day. The actual quantity of water required was not very great; for by providing a settling tank to receive the discharge water, the silt and débris soon settles, and thus the same water can be used over and over again. However, the very fact of any water being required, even for working the engine, will restrict the use of this apparatus very much indeed in Australia.

Upon

Upon reference to plate III, fig. 4, it will be observed that on the upper hollow boring bar *a* is screwed a short length, *b*, carrying a cast-iron chamber, *c*, in the base of which the head of the short bar *b* can revolve freely between brass washers, at the same time making a comparatively watertight joint; on the same bar is keyed a spur wheel, *d*, into which a pinion-wheel, *e*, gears; this pinion has a square hole through the centre, travelling freely up and down the 1½-inch square bar *f* at the side; to this bar is conveyed rapid rotary motion through bevel wheels, *g*, which are driven by a belt from the main shaft *h*. As the bars sink in the hole, the pinion slides down the square bar, following the spur-wheel and imparting the necessary rotary motion to it in every position. To the head *c* is coupled the flexible hose leading from the pump attached to the engine.

In this apparatus, as in the hand-boring apparatus, much time is lost when it becomes necessary to draw the rods; but of course, owing to the débris being conveyed out of the bore by the water, the rods have not to be so frequently drawn; but when a gravel bed is passed through the large stones cannot be washed up, and the rods must then be drawn, and a large-valved sand-pump lowered down to bring up the shingle, &c. With this apparatus I saw hydraulic pulling-jacks, very suitably applied for drawing down the casing, which will be described further on, one man attending them drawing down the casing, while the second man attended to the engines and boring apparatus. An ingenious and simple device for suspending the rods in the bore while adding on casings is shown on plate II, fig. 3. This is simply a round piece of pine, nearly the diameter of the casing, cut in three pieces, the central portion being wedge-shaped. Into this piece is fixed a length of bar with spigot and socket screwed unions; this is screwed on to the top of the rods and lowered; when a short way down the side pieces are checked with a string; the weight of the rods drawing down the central wedge causes the blocks to jamb in the casing; there they remain suspended till the upper bar is lowered down, screwed on, and pulled up, thus drawing the wedge and permitting the rods to run up freely.

It is only right that I should mention that Messrs. Jerome Haas and James Manning, of Stockton, California, U.S.A., contractors for well-sinking, have brought this system to great perfection, and have taken out several patents for improvements in the various parts of the apparatus.

Drilling Apparatus.

The drilling apparatus ordinarily used for sinking wells not exceeding (say) 800 feet deep is shown on plates Nos. IV and VI. These are both handy and portable machines; they are usually provided with an axle and wheels, which enable them to be transported across country easily, all the gear, horse-power, &c., being stored on top for transit.

When holes have to be sunk much greater depths, such as 1,500 to 2,000 feet, then it is desirable to use much heavier appliances driven by steam, and what is known as a walking beam or Pennsylvanian rig becomes necessary; this is, however, seldom made in a portable form, a fresh derrick being usually erected over each hole. Nearly all drilling apparatus for bores from 600 to 800 feet deep are worked on the same principle, so one description practically answers for all.

The derrick, shown on plate IV, fig. 1 (and partly enlarged at fig. 2) has two working barrels; on one is wound sufficient 2-inch rope, termed "the sand pump line," to reach the bottom of the deepest bore required, and the second barrel carries the drill cable, which may be either a hempen or Manila rope of similar length and about 5 inches girth; this rope passes from the barrel over a sheave, fixed halfway up the derrick, then down and through what is termed the Pitman sheave, *a*, in fig. 2, then up and over the sheave at the head of derrick, and finally down and made fast to the head of the drill bars.

The drill bars are made up as follows:—

First the bit,	... ...	about	4 feet long
next ,,	auger stem	,,	12 ,,
,,	jars	,,	5 ,,
,,	sinker bar	,,	8 ,,
,,	rope socket	,,	1 foot long
	In all say		30 feet long.

The above lengths may vary very much, of course, according to circumstances, the bars used for deep oil wells being made up as much as 60 feet long and up to 4 inches diameter; those used for shallow holes need not exceed from 2½ inches to 3 inches diameter.

The derrick is first set up true over the centre of the bore, and the casing sunk (say) 8 feet, as before described, to start the hole fair; then the drills may be lowered into the bore and started. From the sketch given of the gearing, it will be seen that the horse power or engine may be kept constantly going, clutches being provided for throwing either of the barrels or the Pitman sheave into gear when required. When the clutch at *b* is put into gear, the Pitman sheave is given an up and down motion equal to twice the throw of the crank on the end of the shaft *c*. As the drills sink, the rope is lowered out by applying a pinch-bar or feed-lever to the brake wheel *e* and bearing down on it till the pawl in the wheel on the end of the cable drum *d* can be released; then hold the brake and lower out as much cable as may be necessary, and when the tools reach the bottom again throw in the pawl. The lever marked *f* is for working the clutch *g*, which travels on a feather on the driving shaft and engages the cable drum for raising the tools. The lever *h* is for tightening the belt on the pulley on the driving shaft, and enabling it to drive the barrel *i*, which carries the sand-pump line; this may be a light wire rope, to the end of which is attached the sand-pump. It will thus be seen that the tools can be raised rapidly by the cable drum; when they are up and landed disengage clutch *g*, drop the sand-pump into the bore, easing it down if necessary by pressing on the lever *h*; and when filled again press on lever *h* and the sand-pump is rapidly wound up, the engine or horse-power being kept in motion all the time. Thus a very few minutes suffice for raising the tools, clearing out the hole, and lowering the tools down to work again; and the whole operation can be attended to and manipulated by one man, a second man only being necessary for driving the engine or horses; the assistance of the second man is also necessary when it comes to building, and driving or sinking the casing.

When the hole is first started the tools may be kept short by omitting the sinker bar and jars. Should the hole be dry, water must be poured in from time to time, and when the tools stick, draw them and clear out with the sand-pump. As soon as rock is met with it is necessary to add on the jars and sinker bar, otherwise the tools may stick fast in the hole; the loose action of the jars enables an upward blow to be given, by shortening in the cable and continuing to work the Pitman sheave; when an upward hammering action is imparted to the tools this seldom fails to start them up. Should the tools be found to stick, through the hole getting out of shape, one of the reamers, shown on plate V, figures 17, 18, 19, should be used to true up the hole before proceeding with the drilling.

The description above given more particularly refers to the Gillespie Tool Company's machine, but the same will almost exactly apply to the Pierce machine, plate VI. I saw both machines at work at different places, and, on the whole, would give the preference to the Gillespie apparatus, as being the more compact, but in actual work I doubt whether there is any practical difference between them; both being good and well designed machines, and, I believe, the best for the work to be found in the States.

Pennsylvanian Rig.

As I have referred to the Pennsylvanian oil rig, a brief mention of its principle may not be out of place here. This machine is specially arranged for deep sinking, when bores 1,500 to 2,000 feet or over are necessary. In this case the tools are made up exactly as before described, but larger and much heavier; tools 4 inches diameter and 55 to 60 feet long are generally used for deep 7 and 8-inch holes.

Over the site fixed upon for the hole is constructed a derrick, as sketched on plate No. VII. This derrick should be not less than 70 feet high, 20 feet square at the base, and 3′ 6″ at head. The corner timbers of the framing may be 6″ × 6″ pine, or 4″ × 4″ hardwood, well braced on all four sides horizontally and diagonally. At one side is firmly set up a Sampson post, on the head of which is placed the walking beam. Under the outer end of the walking beam is placed a Bull wheel, carrying the cable, and on its end a crank, or what was before termed the Pitman, for imparting the reciprocating motion to the walking beam. The Bull wheel is driven by belting from a steam-engine, set up in a shed some 20 feet back. From the inner end of the walking beam is suspended a rod, with the temper screw (fig. 2) attached thereto. The bore is usually started by what is termed spudding—*i.e.*, working the tools direct from the Bull wheel, lifting and dropping by slacking or surging the rope on the wheel; once they are their own depth below the surface the walking beam is brought into play. The rope is thrown off the Bull wheel, and the end caught by the temper screw; the drilling motion is then imparted to the tools, and, as they sink, the temper screw is slacked out, thus lowering the tools, at the

the same time turning them and preventing their striking twice in the same place. The nut of the temper screw is split and held by a clamping screw, so that the leading screw can be quickly shortened in by slacking the clamping screw; at the same time a corresponding length of rope must be given out, by releasing and reclamping it in a fresh place. When the bore needs clearing out, the rope is taken on to the Bull wheel, and the tools quickly run up; the sand-pump, which is worked by a light line on a second reel, is lowered down and the hole cleaned out. In all operations of drilling, too much care cannot be taken to ensure the bit or drill being kept up to proper gauge. For this purpose it is desirable to have a duplicate of each pattern of bit used, and, with the help of a portable forge, which should always accompany a drilling outfit, the spare bit can be forged to gauge and got ready for work again without delaying the drilling. The club bit, with its hollow or grooved centre, is specially designed for conveniently forging to gauge.

This class of drilling has been carried on to such a vast extent through the oil regions that the men engaged in the work have become remarkably expert, so much so, indeed, that a bore 1,200 feet deep can often be put down in about twenty-five days, and at a total cost of about $2,000 (say £400). I visited the Bradford, Pennsylvania, district early in June, 1883, and saw from local statistics that during the month of May 226 bores had been completed, and on the 1st June that year 384 bores were in progress in the neighbourhood.

Upon completion of the bore, and if oil has been struck, the derrick, together with the walking beam, engine, &c., is usually left in place; for although the hole may spout oil at first it will most probably cease to flow after a time, and then pumping must be resorted to. A pump barrel, with the necessary foot-valves, &c., is then let down the bore and there fixed and worked by long sucker rods, the upper ends of which are attached to the walking beam, which, as before described, is set in motion by the engines and the oil thus pumped to the surface; but should the bore prove a failure and miss the oil, then the rig is usually removed, but in some parts, where timber is plentiful and cheap, it hardly pays to dismantle and remove the derrick. Throughout the oil regions the hill-sides and valleys may be seen thickly dotted over with derricks in all directions close together.

Although I have described the Pennsylvanian rig at some length, I hardly think it will be necessary to introduce it into this Colony for the purpose of searching for water.

Casing.

Hitherto I have referred to casing in connection with the bores, but without describing it. A few words as to the various kinds of casing, their manufacture and mode of sinking, are here necessary.

The class of casing I saw almost wholly used in California was what is termed riveted sheet-iron casing, as shown on plate No. VIII, fig. 1. It is usually made from No. 14 B. W. gauge sheet-iron, in 2 feet lengths, double thickness; at the bottom is a forged steel shoe (see fig. 2), turned with a cutting edge, and bored internally for the reception of a short length (about 14 inches) of inner casing, to which it is riveted; outside this comes a 2-feet length of the outer casing, which then stands 1 foot above the inner length. The tube is then built up of alternate lengths, each 2 feet, of inner and outer casing, thus breaking the joints 12 inches. The casings are made an accurate fit for one another, well tarred before driving together, and two or three rivets put in to secure them. The apparatus used for punching them on the ground, when building over the bore, is shown at figure 3. In country where saline waters are met with it is doubtful whether it would be wise to use this sheet-iron casing, there being so many surfaces exposed to corroding action that probably the iron would not last long; in most cases, therefore, it will be found cheaper in the long run to use the more expensive screwed tubes hereafter described.

The boring or drilling tools, having to work within the casing, necessarily leave a considerable amount of the surrounding soil to be cut away by the cutting edge as the casing is forced down; this is found a desirable arrangement, as it ensures a close fit which cuts off surface or bad water contained in the upper measures from the pure artesian water reached at lower depths.

Should a hard vein of indurated sand, or soft rock, be passed through by the drill, it may be found almost impossible to force the casing through it; in this case the side must be reamered out by an expanding reamer, such as that shown on plate II, fig. 5, thus enlarging the bore to the outside diameter of the casing.

The most usual method I found practised of sinking casing was with a lever, as shown at plate VIII, fig. 6; some planks are buried in the ground, or otherwise suitably loaded to secure the fixed end of the lever to, and then the other end of the lever which rests upon the casing is weighed down, either by the weight of the men, or by applying a purchase tackle to it. A suitable cast-iron cap, fig. 7, must be placed over the head of the casing, for the lever to rest upon during the operation of sinking, to prevent its being crushed or injured.

In some ground the casing sinks very freely. I saw some sinking by its own weight when at a considerable depth (over 150 feet) below the surface; it very frequently happens however that the surrounding friction becomes too great to admit of the first or 7-inch casing being sunk over 200 feet; when this happens a 6-inch casing must be lowered down inside till it reaches the bottom (the tool shown at plate V, fig. 14, being suitable for this purpose); the boring may then proceed as before, but of course with a smaller bit. The weight of the free length of the 6-inch casing helps very materially in the sinking; it will occasionally follow the auger for as much as 70 feet below the 7-inch casing before any forcing down becomes necessary. As soon as water is reached and the boring is stopped, the 6-inch casing can be cut off about 8 or 10 feet above the bottom of the 7-inch casing, by the tool shown at plate II, fig. 6, or a tool somewhat similar to the reamer shown at fig. 5, and the upper portion drawn out, taken apart, and used again in another hole; the same tool, plate V, fig. 14, used for lowering the casing, can be used again for drawing it up.

Another method of sinking casing is by using hydraulic pulling jacks (see plate III, fig. 6). A suitable cast-iron head, fig. 5, which carries a hook at each side to attach the pulling chains to, is fixed over the pipe; two 4 or 5-ton pulling jacks are buried in the ground, one at either side, their lower ends being securely fastened to a framing, which must be previously buried in the ground some 8 feet deep round the casing; the jacks are run out full length, and the long-linked chains upon being drawn up tight are attached to the hooks in the casing cap; the jacks are then pumped down, drawing the casing with them; of course when steam is used this is a simple process, still it is effectively, although at a much slower rate, done by hand. This method has the advantage that one man can be pumping or forcing down the casing at the same time that the other men are carrying on the boring.

A third method of sinking casing is by driving it; this is very simply done when a drilling machine such as the Gillespie Company's is used, for by taking a bolt out of the Pitman crank, a^1 (see plate IV, fig. 2), a peculiar drop action is given the Pitman sheave; it is then only necessary to detach the drills from the end of the cable, hang on the driving weight (plate VIII, fig. 8), place a good block of wood over the head of the casing, with a hole through it to guide the pin shown to project from the weight, then start the machine, and a series of rapid blows can be given to the casing sufficient to drive it down.

Cost of Casing.

The cost of the 7-inch riveted casing, double thickness, delivered on the ground in California, I found averaged 75 cents (say 3s. per foot), and the 6" similar casing cost 60 cents (say 2s. 5d. per foot); this is based on sheet iron costing 3d. per lb, = 28s. per cwt., delivered on the ground.

One great advantage in the use of riveted casing is that the sheets can all be cut and punched true to gauge for inner and outer lengths at the factory, and a number of plates can be safely packed together and conveniently sent up the country, where a very simple curving machine can be at hand to bend them; they are then riveted with cold rivets. There is nothing in the whole process that any handy man could not learn to do in a very short time, with the very simplest appliances.

A more permanent class of casing is made from lap-welded tubes, which can be procured in lengths up to 18 or 20 feet, turned and machine-screwed at the ends as shown at plate VIII, fig. 4. As this class of joint cannot be made on pipes less than about $\frac{1}{16}$ inch in thickness, the cost of such casing is considerably greater than the riveted, but it would certainly be found more durable and safer to use in sinking. The cost of such casing properly screwed, landed in Sydney, would be about 7s. per foot for 7-inch, and 5s. per foot for 6-inch, assuming it to be obtained in fair quantities. There are various ways of making the screwed joints, two of which are shown on figs. 4 and 5. The latter is the cheaper, but that shown at fig. 4 is the better, being the only one that secures a flush surface inside and outside the pipe, which is a most important matter.

A cheap casing is sometimes used in America, made in lengths of 14-gauge sheet-iron wound spirally and riveted along the edge (see plate II, fig. 4). I do not think this can be recommended except in very soft ground, for it is not strong enough to stand the end crushing strain necessary to be applied when pushing it down the bore.

Stopping

Stopping back impure Water.

When practicable it is desirable to use casing all the way to the bottom of the bore, but this is really only possible when the boring is through soft measures free from rock; when rock is met with the hole ought to be reamered a little, and the casing let as far as possible into it, to cut off the downward flow of impure water; but should this not prove effectual to stop back the impure water, some device such as that used in the oil wells for stopping the water back from the oil must be adopted. The method for doing this which I heard was most approved of in the oil regions, where it has been applied to nearly every bore to keep the oil free from water, is by the use of what is known as a "cap packer." This is a rubber block 8 inches or 10 inches long, made almost the neat diameter of the bore, and lowered down on the end of an inner tube, (see plate IX, figs. 2, 3, and 5). *a* is the rubber block; *b*, the inner tube, which of course must be carried up to the top of the bore; *c* is the lower tube resting on the bottom of the bore, which in the case of pumping wells acts as the pump barrel when fitted with a foot-valves, the upper valve being attached to the sucker rods; on top of the lower tube *c* is screwed a funnel-shaped piece of pipe, *d*, which widens out nearly to the diameter of the bore, and is turned with a seat on its upper rim to receive a ferrule, *e*, which slides on pipe *b*, and acts as a seat for the rubber block; pipe *b* has a stop ring, *f*, screwed at its lower end, to prevent the block sliding off when being lowered down, and another ring, *g*, at the top end to catch under a malleable iron ring fixed into the rubber block, for the purpose of drawing it from the well when required; there is another collar, g^1, screwed on, which fits the upper end of the rubber block and bears down on it; this also acts as a joint collar for the pipe. The action is therefore as follows: the lower end of the block rests on the head of the lower pipe, and the whole weight of the upper pipes rests upon the top edge of the block, thus compressing and expanding it against the wall of the bore, and effectively stopping the downward passage of impure water.

In the case of artesian flowing wells, the lower pipe, which is not necessary, can be dispensed with by using the same apparatus, but by inserting a cross-bar, *h*, fig. 2, and attaching to it a ½-inch rod of iron, which should be in long lengths screwed at the ends and coupled together and led up to the top of the bore; the inner pipe, carrying the packer at the bottom, must then be suspended from the surface and the ½-inch rod screwed hard up, to bring an upward pressure against the rubber block and thus expand it.

There is another simple way to make a watertight joint, as shown at figs. 1 and 4. This consists of an iron tube, *a*, say 4 inches diameter, with a flange, *b*, screwed on at lower end, against which are bolted two rubber rings; one, *c*, about 2 inches larger diameter than the bore, the second, c^1, placed underneath a tight fit for the bore; these are nipped up against the flange with a ring washer, *e*, and screw bolts. A calico bag about 2 feet long and made the diameter of the bore is secured at its lower end between the flange *b* and the rubber ring *c*. This bag, which encloses an annular space round the tube, is filled with a mixture of half Portland cement and half clean sand, just moistened and made into a stiff mortar; the mouth of this bag is loosely closed round the pipe, which is then pushed down the bore till the bottom reaches sound rock, at a point below the strata containing the salt or impure water; the cement may then be tamped firm home by a piece of heavy tubing, or annular cast iron weight suspended by a rope as shown on sketch. The cement will soon set hard and make a secure and tight joint.

Cost of Machines and Tools.

The cost of the Gillespie or Pierce Machines shown on plates Nos. IV and VI, including an outfit of one rope socket, one auger stem, sinker bars and jars, two bits, two winches, sand-pump and 500 feet sand-line, 500 feet of drilling cable, and a horse-power, the whole suitable for drilling 500 feet deep, would be about £200, delivered in Sydney, to which might be added about £30 for extra fishing tools, pipe riveters, lifters, stubs, &c., making an outfit in all cost about £230; but even this would have to be exceeded in the first instance by any one commencing to bore, as it would be necessary to provide a portable forge, some blacksmith's tools, spare iron, &c. For going 600 feet somewhat heavier tools would be necessary, but with the same machine the cost would be about £240; by purchasing a supply of spare box and pin stubs, a great many of the special tools shown on the drawings could be made by any ordinary blacksmith and the stubs closed on.

The boring machine outfit would not cost over £80 complete. Excepting the horse-power and crab winch with connecting gear and the screwed ends for the wooden and iron pipe rods, there is no part that could not be made up the country by any carpenter and blacksmith. Most of the machines of this class which I saw at work were evidently constructed by the owners, who in most cases I found had been mechanics, blacksmiths, or general handy men, well able to make all their own tools, as well as the numerous special tools that are found necessary from time to time during practical working.

In situations where many bores may have to be put down, and where water and fuel can be conveniently obtained, I would certainly recommend the use of steam instead of horse-power, for expediting the work, and thereby lessening the cost of labour. Almost any make of portable engine can be adapted for the purpose. To run a 600-feet drilling apparatus an engine of about 5-horse power would be ample. For the generality of work, however, I believe the ordinary horse-power machine will be found sufficient, though of course slower, both horses and horse-keep being cheap and always available throughout the country.

It is unnecessary here to refer to the cost of steam-engines, as full information can always be obtained from any Sydney importer.

American well-drilling tool catalogues quote prices for engines, but English-made engines can be landed in Sydney much cheaper.

Cost of Boring or Drilling.

As regards the cost of boring or drilling, I found nearly the one price ruled all through the country; no matter what kind of apparatus was used, a set contract price seems to have become established. What the net cost was I could not well find out, but of course it would vary a little in every case; but seeing the eagerness with which contractors sought for and took orders, it is evident the contract rate quoted below pays well.

The rates are as follows:—

	s.	d.		£	s.	d.
0 to 100 feet — 100 feet @	2	0	per foot	10	0	0
200 to 300 ,, = 100 ,,	3	0	,,	15	0	0
300 to 400 ,, = 100 ,,	4	0	,,	20	0	0
400 to 500 ,, = 100 ,,	5	0	,,	25	0	0
500 to 550 ,, = 50 ,,	6	0	,,	15	0	0
550 to 600 ,, = 50 ,,	7	0	,,	17	10	0
Cost for boring hole 600 feet deep				102	10	0
To this must be added cost of casing, which, as before mentioned, cost when riveted 3s. per foot.						
600 feet 7-inch casing, at 3s.				90	0	0
Add to this the cost of boarding the contractor and his two men, as I found was the practice for the farmers for whom the work was being done to keep them while at work, say three men for six weeks = 1 man for 126 days at 2s.				12	12	0
Total cost for a 600-feet hole				204	2	0

Say 6s. 10d. per lineal foot.

If a length of 6-inch casing had to be used the cost would be reduced a little. I have allowed six weeks for the boring; this is the outside time a 600-feet hole would occupy, unless some serious mishap occurred to delay the work. I have already mentioned a case where with the hydraulic boring apparatus a hole had been sunk over 500 feet in 11¾ working days. It must be borne in mind, however, that in this case a steam-engine was used, and when an allowance is made for procuring water, fuel, stores, &c., the cost of the work will nearly mount up to as much as the slower horse-power machine.

ARRANGEMENT ADOPTED IN CALIFORNIA FOR IRRIGATING FROM AN ARTESIAN WELL.

Upon the completion of a bore, if it prove a flowing well, the casing is left standing from 4 to 5 feet above the surface; an area of about an acre is then enclosed to form a reservoir around the well, by raising a mound of earth (say) 5 feet high; the land around is cut up into about 5-acre paddocks, termed "checks," and properly levelled off for irrigation; four main feeders, termed "ditches," are constructed from the central reservoir along the boundaries between the checks, the bottom of the ditches being kept a little above the surface of the check; very simply constructed wooden gates are placed at the opening to each ditch, by raising any one of which the water can be led along the ditch and again let out through side gates over any one of the surrounding checks needing irrigation. It will thus be seen that the storage reservoir, which holds about one and a half million gallons, is filled by the well, and emptied daily, or as the land needs it, by running the water off through the various ditches. I was informed that the farmers generally considered a good well sufficient for irrigating from 160 to 200 acres of tilled land. An arrangement of dams, ditches, and checks, such as above described, is shown on Plate X.

I experienced great difficulty in obtaining information as to the quantity of water discharged from any of the wells; the amount of course varies considerably. Only in one or two instances could I get near the tube to measure the height the water rose over the lip of the pipe; for, as already mentioned, they invariably stood out in the centre of a round reservoir some 4 feet or so deep.

I measured a few that I gained access to, and in these instances I found the water rose from 2 to 3 inches over the lip of the pipe, the local practice being to speak of the well as an inch, 2-inch, or 3-inch flowing well, as the case might be. I only saw a few 3-inch wells, and they were considered amongst the best. I estimate the discharge from a 3-inch well would be about 550,000 gallons per twenty-four hours, and from a 2-inch well about 350,000 gallons per twenty-four hours. Of course there are cases where the artesian water rises under very heavy pressure. When such are found, pipes can be connected with the casing-tube, and the water led away for supplying buildings.

A portion of the town of Honolulu, in the Sandwich Islands, is supplied from an artesian well in this way. I there saw some wells discharging under very heavy pressure—one was throwing water through a 5-inch pipe to a height of at least 25 feet into the air—but in California I did not see or hear of any such wells.

TORPEDOING WELLS.

The system adopted in Pennsylvania known as "torpedoing," for increasing the flow of oil wells when first bored, might perhaps be found of use in artesian wells.

When the oil-bearing strata is reached, and the boring is considered deep enough, a heavy charge of dynamite, with a fuse attached to it, is let down to the bottom of the well—or, better still, the dynamite charge may be lowered down with insulated wires attached, and when on the bottom fired by a portable battery on the surface. The explosion shatters the surrounding rock, opening the joints, and allows a free escape of the oil to the bore. Although this method is almost universally adopted in oil wells, I never heard of its being tried in a water-bore, but I think the experiment would be worth trying with a light charge in a case where water may be met with on strong ground.

SUGGESTIONS AS TO IMPORTING APPARATUS.

I have not had an opportunity of making myself acquainted with the nature of the apparatus that has been tried or now is being used in this Colony for drilling or boring for artesian wells. I am aware the diamond drill is being largely used for boring to test for minerals, but for the purpose of obtaining a water supply such drills are quite useless, owing to the small bore. Diamond drills can of course be made for all sizes up to 20 or 24 inches diameter, of which latter size I have seen one, but when the ordinary small bore is exceeded the cost increases rapidly. Should the Government not have already imported any machine such as I have described in my report, I would recommend that an order be sent to either the Gillespie Tool Company or the Pierce Well-excavator Company—or perhaps to both—to send out a machine and complete outfit suitable for drilling 500 to 600 feet deep; also, that they be requested to send out an experienced man with their machine to work it here upon arrival. I am sure either of the manufacturers would for their own sake select a skilful and trustworthy man, who would soon train others here into the work. Should the Department in charge of the water-augers once show that boring can be done expeditiously and at a reasonable expense, I am persuaded that private enterprise will not be slow in coming forward to import the appliances found most suitable, and that in a few years' time the Government will be entirely relieved of the trouble of carrying on this work, except through the medium of contractors.

In the event of any one having read the foregoing notes wishing to write to America for further information about the various machines referred to, I give the addresses of the makers whose names I have mentioned.

APPENDIX J 3.

GILLESPIE TOOL COMPANY—MANUFACTURERS OF DRILLING MACHINERY AND TOOLS, PITTSBURGH, PENN'A., U.S.A.

An all-wise Providence has placed within the reach of man, no matter where situated upon the habitable globe, the means of procuring an abundance of pure, fresh, and health-giving water.

In the great deserts of Egypt, during the late Arabi Pasha and English war, necessity and Yankee invention developed the fact that an abundance of pure water could be obtained wherever needed. The great African desert has been pierced and yields up the *aqua pura*, and it is a settled fact that fresh water can be procured anywhere through its vast extent by the use of machinery at a nominal cost. French engineers have sunk a hundred wells in this desert, which yield 600,000 gallons of water per hour, and bring under a high state of cultivation a large space of land.

The great American desert, extending from Dakota in the north to the Rio Grande in the south, including the staked plains of Texas, have been discovered by the U. S. Bureau of Agriculture to be underlaid with a great abundance of water for household, stock, and fire department purposes, and for irrigation. In many sections of the United States water is held in a pervious formation, communicating with the snow-capped mountains of the north and west, and wherever that pervious formation is tapped by the drill the water flows above the surface, and there is no place in the country where water will not rise in the drill-hole to within an easy pumping distance from the surface.

Manufacturers and brewers in all cities are learning that it is cheaper to drill wells at their works than to pay the exorbitant license for the uncertain supply furnished by waterworks. Most of the brewers of New York have already drilled artesian wells. The Waterloo Woollen Manufacturing Company of that place have a well flowing 9,000 gallons per hour; at the U. S. Mint, Philadelphia, is a well 450 feet deep that flows 90,000 gallons per day; at the Belshar Sugar Refinery, St. Louis, is another that flows 108,000 gallons per day; another at Louisville, Ky., that flows 330,000 gallons per day; a well drilled at Grennelle, France, flows 21,000 gallons per hour; another at Passy flows 62,000 gallons per hour; Pesth, Hungary, has a well flowing 17,000 gallons per hour; London, England, has a large number of flowing wells, and artesian wells are now being made in all civilized countries. In California it is estimated that there are over a thousand artesian wells, averaging 125 feet in depth, most of which are flowing. Flowing wells have been drilled at Fargo, Dakota, Prairie du Chien, Wis., Pueblo, Col., Ft. Worth and Dallas, Texas, Lake Charles, La., Coolidge, N.M., and in many places in Mississippi, Alabama, and Georgia, and every well drilled creates a demand for more.

The pioneer of our country is excusable for depending upon seep springs and branches for his supply of water, for he is generally without the means of sinking deep wells and the water has not been contaminated; but as the country becomes settled the seep springs dry up, and the ponds and branches become receptacles of liquid filth and offal, breeding an effluvia laden with malaria, poisons, and the germs of disease, which account for many a tear-moistened grave and early wrecked constitution. As the water in the ponds and branches becomes more filthy and unpalatable the water-cart is resorted to and the liquid is hauled from spring or larger body, often many miles distant, where the poison can be gotten in milder doses for family use, while the domestic animals are left to their choice to drink the poisonous mixture from the cesspools or suffer from thirst. The same laws of health apply to man and beast, and any good stock-raiser knows that pure fresh water is one-half of the requirements for the growth and satisfactory development of his stock.

We herein describe the means of procuring water at any point desired, without resorting to the pick, shovel, and fuse, or the risk of being buried alive or suffocated by foul air.

Oil, Coal, Minerals.

Previous to Col. Drake's tedious experience in sinking the first oil well, near Titusville, Pa., in 1858-9, nearly all wells and prospect holes for coal and minerals were made by the old slow, dangerous, and expensive process, requiring the workmen to go down into the well, at the constant risk of life and limb. The discovery of oil developed a necessity for a quicker, safer, and more economical method of sinking wells, and the result has been the invention of many devices for the purpose, but up to this date the Pennsylvania Drilling Machine made by us is the only rock-drilling outfit made that is adapted to the purpose of drilling through rock, and the only combined earth-excavating and rock-drilling machine in existence. There are many so-called combined well augers and drilling outfits in the market, but in all cases they consist of two complete machines, with the exception of some few minor parts that are interchangeable. To claim that such an outfit is a combined machine is absurd, for no one machine can impart a rotary motion to an earth auger and a vertical motion to the drilling tool.

A combined machine for making wells in earth as well as rock must use the same mechanical movement in the earth-excavating as in the rock-drilling, and the Pennsylvania Driller is the only outfit in existence that accomplishes that great desideratum.

The simplicity, portability, and lightness of our machine make it specially adapted to the sinking of prospect holes in a mountainous or distant country, where more cumbrous outfits could not be used, and the item of freight is no small object.

Warranty.

The Pennsylvania Driller, made by us, is warranted to be well made, of good material, free from defects in workmanship, and to do as rapid work in earth and rock with as little draft on the team or engine, as any other earth-excavating and rock-drilling machine in the market, or the purchase money will be refunded.

Our Terms of Sale.

It frequently occurs that patrons are abundantly responsible for the price of an outfit but have not the ready cash to pay for a machine, but can pay one-half the amount at the time of purchase and give good security for the balance with interest until such time as they are able to make the money by sinking wells by contract. To such we would say, send in your orders, and state the time required and the security offered, and if satisfactory we will accept and fill your orders in their regular order. Unless the party purchasing is known by us to be responsible, or can give satisfactory security, we shall require payment in full on delivery under the terms of our warranty.

A Good Investment.

In all neighbourhoods there are many persons engaged in threshing by contract, the majority of whom own portable engines; to such we would say, that by purchasing either our light outfit No. 1, or our No. 2 heavy outfit, you can use your engine to operate our Pennsylvania Driller out of threshing season, and make more money every day you run it than you can with our separator in its best season. There are always plenty of your neighbours wanting new wells or their old ones made deeper, and every drilled well made creates a demand for others, so that the more wells you drill the more you will have to drill.

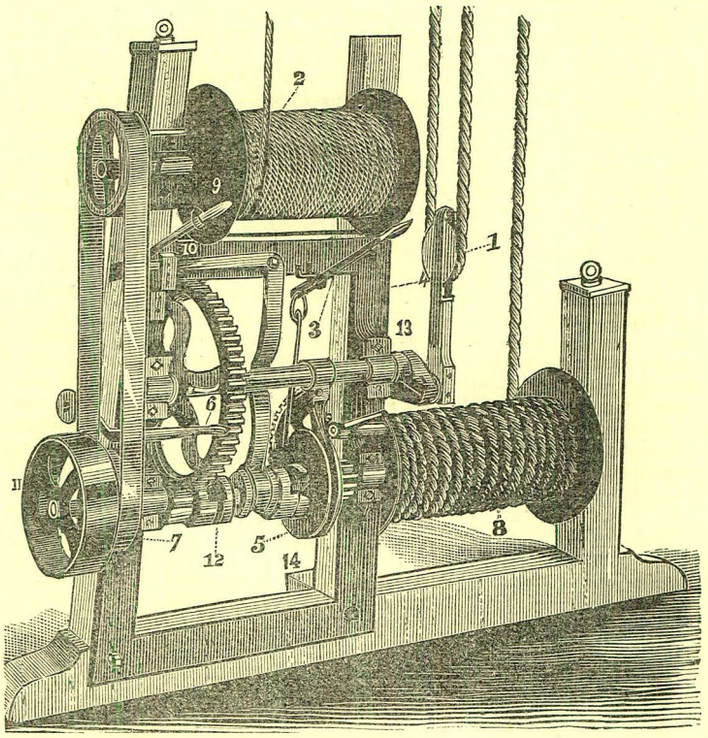
There are over twenty portable drilling outfits in this country on shallow wells for water, and the operators have more work contracted for at good prices than they can do in the next six months.

How the Farmer can make more Money during the Winter than at Farming in Summer.

Between farming seasons there is a time when the farmer has a good deal of capital invested in work-horses that nearly "eat their heads off" while they are doing nothing to earn their feed. If such a farmer owned one of our light drilling outfits with a sweep power to put his horses to work on, he would profitably employ the capital invested in his horses as well as the machine; and many who have tried it have found the business so profitable that they now rent out their farms and follow the drilling business as a more agreeable and profitable occupation. Our horse power is well adapted to general farm purposes, such as sawing stove wood, grinding apples for cider, shelling corn, cutting fodder, and grinding chop-feed, as well as drilling, so that many a large farmer and stock-raiser would find it profitable to own one of our outfits, whether he drilled for others or not.

Why small Wells are better than large ones.

There is a very general opinion among parties who have not studied the matter closely that a well of small diameter will not contain water enough to supply their demands in time of a drought, and think a well of large diameter will hold a surplus to draw upon at such a time. Now everybody knows that if the supply of water is limited, the surplus is soon exhausted, even from a large well, and no matter how large the hole, it is impossible to obtain more water from it than the conditions of the ground or rock surrounding it will furnish; and it is very evident that a deep small hole will penetrate more water-bearing formations than a large shallow hole, and the small hole will as effectually drain the water-bearing formations as the large one; and no matter how few gallons of water may seep into the small well, it can be pumped out without becoming muddy. A well 5 feet in diameter, containing one barrel of water has the bottom covered only 3 inches deep. A well 1 foot in diameter, with the same quantity of water, is filled 7 feet from the bottom, and a well 5 inches in diameter 29 feet. It is too well known how filthy the bottom of a large well becomes to mention it here. As the water fails, the dregs are stirred up, and drained and stirred again; but a small well, securely curbed with cement, tile, or terra cotta curbing, is always mud and rat proof, and even a small quantity of water in it is always pure and wholesome. A 5 or 6-inch drilled well can be made much deeper, for the same outlay, than a large one; and the deeper the well the less liable it is to be affected by drought, as the subterranean watercourses are never affected by surface or atmospheric conditions.



Illustrated Cut of the Pennsylvania Driller, showing the mechanical details, the different parts numbered and described below.

No. 1 is the Pitman sheave.
„ 2 „ „ sand reel.
„ 3 „ „ brake lever.
„ 4 „ „ bedplate, to which the working parts are attached.
„ 5 „ „ brake pulley and hoisting pinion.
„ 6 „ „ sand reel lever.
„ 7 „ „ sand reel pulley.
No. 8 is the drum for drilling cable.
„ 9 „ „ lever for throwing the clutch in and out of motion.
„ 10 „ „ lever support.
„ 11 „ „ driving pulley.
„ 12 „ „ clutch.
„ 13 „ „ crank.
„ 14 „ „ stirrup for holding derrick pole.

The Pennsylvania Artesian Well-drilling Machine.

The drill jack is built independent of the derrick. The jack is a strong wooden frame built of hard wood, with all the machinery, crank motion for drilling, driving shaft, hoisting rig, feed work, and sand reel all neatly fitted and fastened thereto. The derrick consists of two poles or timbers, jointed at the top and fitted with crown pulleys ready for the drill rope and sand-line. To connect the derrick to the jack, lay the jack down on its face, then enter the tenon on lower end of derrick pole into the stirrup on the jack and shove it into the stirrup, then put the bolt through top of the jack and put on the guy rods and connect the derrick at the top, after which it is ready to raise. In raising it, two men will take hold of derrick pole and walking right up with it until the derrick is as straight as desired. When the derrick is in position, put in the cable line and tools, and your machine is ready for work.

How to put on the Cable.

First take the coil of drill rope and find the outside end of it and rivet on your rope socket, after which take the other end of the rope and put it over the crown pulley on top of derrick. Draw it down along the mast to figure 4 (see above), and put it through the sheave toward the direction of fig. 1, and from there over sheave midway in the derrick and thence down to the drum (fig. 8), fastening it to the drum or the flange on the drum by means of a bolt through the flange. One man will then take hold of the drill rope and the other man starts the machine by the lever (fig. 9); draw the pin out of the lever support (fig. 10) with one hand and lower the lever with the other hand until the drum starts, and when the rope is all on, raise the lever above the first hole and put the pin in the lever support (fig. 10), and this stops the drum.

To start the Drilling Motion.

Raise the lever (fig. 9) as high as you can and put the pin in the upper hole of lever support (fig. 10), and you start the drilling motion. To stop it, draw the pin and place it in the lower hole of lever support (fig. 10) and drop the lever (fig. 9) on the pin, but your engine or horse-power may still run on. The lever (fig. 9) is used for starting and stopping the drill, and for raising the tools out of the well. The lever (fig. 6) is for raising and lowering the sand-pump, which will be seen by the cut. Fig. 3 is the brake lever for lowering the tools in the well.

Fig. 5 is the brake pulley and feeding device attached; you will find the holes in the side of the brake pulley. A small iron rod, pointed, is sent along with each machine; this is used to insert in the holes in the feeding device, and is called the feed lever. To lower the tools, put the feed lever in the holes and bear down until the pawl is loose or detached from the wheel or drum, then bear down on the brake lever (fig. 3) and draw out your feed lever, raise the pawl, after which raise up on the brake lever until the tools descend into the well; when they are at the bottom of the well, drop the pawl and commence drilling.

How

How to commence a Well.

Should the rock be below the surface and you should have to drive pipe, connect the rope socket, auger stem or drill bat and the bits together (leaving the jars out). Then raise the tools high enough to admit of your joint of pipe, and plumb or steady the pipe with the tools and fasten it temporarily. Make a cap from a block of wood, made so as to fit into the socker of the pipe, and bolt this block of wood to a piece of iron, and insert this in the upper end of the pipe. When this is done, take the bolt out of the crank on the driller, and this gives you the "drop motion" of the machine. One man should steady the tools, while the other man starts the machine, and commences driving the pipe. As the pipe descends at each blow you will gradually let out rope, just as it is required by the pipe going down. Continue driving the pipe as long as it will go down; when the driving becomes difficult, remove the cap from the pipe and lower the tools down inside of the pipe; start your machine again just as you did when commencing to drive pipe, and begin drilling. Pour in a few pints of water, so it may mix with the dirt, take hold of your drill rope, and turn a little at every stroke of the tool; continue pouring in water and drilling until your tools commence to rub or stick a little; then draw your tools and run down your sand-pump and clean out; then start your tool again and drill again until you are within about 6 inches of the lower end of the pipe, after which you will commence to drive your pipe again. In no case drill below the bottom of the pipe until you are satisfied you have come to rock, after which you will dress your bits exactly to the gauge, and be sure and always have them fit the gauge. Drilling in the rock is like drilling in the pipe; you can drill until your tools commence to stick or drag a little, when you should draw the tools at once and sand-pump. Always use the jars when done driving pipe, for it is the safest and most practical way of drilling; without the jars your tools may stick, and you may not be able to get out. Please follow the instructions, and you will have better success with your work, and the machine will give greater satisfaction.

To Load and unload the Machine.

Every machine is provided with trucks, inserted in the base of the machine, so that it will roll quite easily on a plank lengthwise. After you have disconnected the derrick from the jack, back your waggon up close to the jack, and take off the hind wheels and lay them down on their face, directly under the spindles of the axle. This, of course, lowers the hind end of your waggon close to the ground. Take two pieces of plank, and lay one end of each on the waggon and the other end on the ground. Now take hold of the jack and roll it in the waggon near the front end and lay it down on its back; after this is done, take hold of one wheel and raise it up so it will slide on the spindle, and do the same with the wheel on the other side of the waggon, and your jack is loaded. Put in the two poles or derrick, horse-power, and your tools, and you are ready to move. Unload the machine in a similar manner. Two men should do this inside of one hour.

Steam or Horse-power.

The "Pennsylvania" can be run by steam or horse-power, and we claim that we can drill as fast with either steam or horse-power as any rock-drill manufactured. But we do not wish any person to think they can do as much work with horse-power as with steam-power, for the simple reason that when a man buys a steam outfit it is an engine from 6 to 10 horse-power, and when he buys a horse-power it is generally for one or two horses. You may receive circulars from other manufacturers that will state how fast their machines will drill with horse-power, making it as speedy as steam-power; but if you will stop and think for a moment, you will see that it is false and calculated to deceive, for the reason, you cannot do six horses' work with two. It makes no difference what machine you have; if you will apply as much horse-power as you do steam-power you will surely do as much work, but the expense will be greater.

APPENDIX K 1.

On Wells in Liverpool Plains, by Mr. T. K. Abbott, P.M., Gunnedah. Read before the Royal Society of N.S.W., 3 November, 1880.

Some few years ago, at the request of my friend Mr. Russell, I was induced to institute a series of inquiries with the view of ascertaining the depth at which the underground springs may be relied upon as permanent in the district in which I reside. I regret that I met with but little success at first, and found existing in the minds of the proprietors of runs a disinclination to impart the information desired. Gunnedah being nearly centrally situated in the Liverpool Plains, and the general character of the plains in the interior of this Colony being somewhat similar, I thought that if I could obtain reliable data as to the depth at which water was found in wells throughout this district, it would be a fair index of what might and probably would occur in other parts of the Colony where the surroundings were like. So little success did I meet with, and so slowly did the information I required come to hand, that this paper which should have been completed and read in 1877 has dragged "its slow length along" to the year 1880. Indeed, on many of the stations in this district I am mainly indebted to the free-selectors for whatever information I possess.

With a view of making the inquiry as complete as possible, I caused to be printed the following paper, which was distributed throughout the district :—

1. Name of station?
2. Position of well, parish and portion?
3. Size of well?
4. Character of surface?
5. Notes of all strata passed through, including thickness and character to first water?
6. Quantity and quality of first water, also remarks on its appearance, *i.e.*, how it came—in rock, gravel, or otherwise?
7. Like account of strata and water to bottom of well?
8. Dip and amount of strata?
9. State instances (if any) which have come to your knowledge where brackish water, having been first struck, has been passed through, and fresh water found?
10. Instances of the reverse (if any) within your knowledge?

The object of these questions was to obtain reliable facts as to the flow of water beneath the surface of the earth. It is well known that rivers taking their rise in the mountains flow for many miles and are eventually lost in the plains. If it could be ascertained beyond doubt that these rivers may be reached by well-sinking or boring it would impart confidence in the permanence of the springs. I believe the area of the watershed of which the water passes Bourke, the Darling, Namoi, Barwin, Gwydir, and all their tributaries, is about 140,000 square miles. The average rainfall at and about Bourke would be 16 inches; thence towards the main range it gradually increases until the high stations have about 40 inches. "In Queensland, from which the Darling at Bourke drains very largely, the rainfall," Mr. Russell says, "would, I should think, be fully 40 inches." Estimating, however, the rainfall throughout at 16 inches, and reducing it over this large area in the usual way for evaporation and soakage, and in order to avoid the possibility of error reducing what remains by one-half, the river at Bourke *should be* 200 feet deep and 200 yards wide, and flow all the year round! At Bourke the river *is sometimes* nearly dry. Where, then, does all this water go?

It is with a view of assisting as far as I can over a limited area towards decisively solving this problem that I have undertaken the collection of facts regarding wells in this district. I can only at present supply a paper upon wells in the county of Pottinger. The information I possess respecting any other of the counties in this neighbourhood is of too meagre a character to submit.

I have obtained, by means of the forms I had printed and circulated, information regarding about 100 wells in the district of Gunnedah, and accompanying this paper I have prepared a plan showing the position of over ninety wells scattered over an area of country amounting to upwards of 2,000,000 (two million) acres. Those who have visited Liverpool Plains are of course aware that the largest and richest of the far-famed pastoral principalities are situated in this county. The plains are generally level; black soil; here and there isolated basaltic ridges of no great elevation; islands of timber and scrub, and sometimes sandstone formations occur.

The object I had in view in preparing the map showing the position of the wells, the general features of the country, and in the schedule attached giving the depth, strata, and all the information I possess, was to place before the members of this Society thoroughly reliable data—so far as it goes—upon which those more able than I may build up theories. My mission has been only to collect *facts*.

I cannot begin better than by giving a description of one of the most remarkable wells in the district, No. 20 on the plan. It is at Bando head-station, at an elevation, I should say, of 100 or 150 feet above the plain. The country is basaltic; and immediately behind the well rises a range of mountains from 1,000 to 1,600 feet higher than the myall slope upon which the well is situated. The late manager, Mr. W. T. Keene, has obligingly furnished me with the following :—"Size of the well, 7 feet square; character of soil at surface, pipeclay; strata, unknown. This well is 90 feet deep, and has 90 feet of water in it. Its history is rather interesting. Prior to the timber being sapped in its immediate vicinity, it was with difficulty that a team of bullocks could be watered. This was about thirteen years since, and during the late drought the well has overflowed continuously." I have frequently examined this well myself, and quite recently I was promised by the present manager the quantity of the overflow. The information has not, up to the present, I regret to say, been furnished. I should estimate the flow, however, at about 20 gallons per minute, and in thirteen years this would amount to sufficient, if conserved, to form a lake 4 feet in depth and 32 acres in extent. The character of the ridges is, as I have stated, basaltic; sparsely timbered with box and ironbark; and in addition to the remarkable overflow of this well which succeeded the ring-barking, several of the little previously dry watercourses are now trickling rills, and convey away from the range, in one instance at least, quite treble the quantity of the overflow from the well. Whether this remarkable state of things is occasioned by the sapping of the timber, or whether it occurs through the operation of natural causes, I am not prepared to state; but it appears somewhat remarkable that the well should have existed for several years, and the watercourses retained their normal condition for a period extending over thirty years, only to develop into permanent springs and streams when the eucalypti were destroyed.

Instances of Salt Water.

Bearing upon question 9 in the form supplied, although not exactly in answer to it, Mr. Keene states :—"I knew of an instance on Colly Blue (Colly Blue is on Coomoo Coomoo Creek, *vide* plan) where an old well 65 feet caved in. The water in this well was limited and very brackish, and hardly fit for stock. A new well was sunk 12 feet to the east of the old one, and at 33 feet a bed of sand was pierced, and an unlimited supply of excellent fresh water obtained." This fact appears to me to be valuable, as it would prove that the water below the surface is held in channels, and may be obtained at very short intervals under widely varying conditions. In the well which caved in the water was obtained at 65 feet, brackish, limited, and unfit for human use. In the second, only 12 feet distant, water, excellent in quality and unlimited in supply, was obtained at 53 feet.

Beyond Bando head-station, and situated on the side of the same range of mountains, there are two remarkable springs called Tambar. These springs are about 100 yards apart, 4 miles from the plain, and elevated above it somewhere over 200 feet. In one the water is contained in a deep cup-like cavity in an otherwise dry and stony-looking spot, and flows across the main road from Boggabri to Coolah. The outflow from this spring varies considerably with the state of the weather. On bright sunny days the flow is only about 120 gallons per hour, and on a dull, cloudy day (although no rain may be falling) the outflow sometimes reaches 400 gallons per hour. The second spring is situated about 40 feet lower than the one just described, and the outflow averages 1,200 gallons per hour. I carefully examined the range, and could not discover the existence of any sufficient catchment from which these springs might derive their supply. My observations lead me to the belief that the fountain-head is situated many miles from where the springs break forth. Upon the plain in front of Tambar some wells have been sunk 100 feet deep without obtaining water. Tambar is elevated over 200 feet above the plain, and the water flows from the surface.

At Bomera head-station there is a well, not numbered on the plan, only 6 feet deep, where the water almost always remains level with the surface, and the supply is practically inexhaustible. This well is distant about 12 miles in a south-westerly

westerly direction from Tambar, and is situated in a sandstone formation on a slope about 200 yards from a creek, the bed of which is 40 feet lower than the water in the well, and this creek is frequently dry. Some of the land in the vicinity has been cleared, but very little sapped. It appears to me to be similar in character to the spring at Tambar, and the fountain-head must, as in the other case, be many miles distant from where it flows. To the north-west of Bando there is a most remarkable spring at Garrawilla head-station, and upon a recent visit I availed myself of the opportunity to measure the outflow. I found that this spring yielded the enormous quantity of 9,600 gallons per hour. I rode over the spring where it makes its first appearance, and was surprised to find the ground quite hollow for a space of upwards of 100 acres, and upon listening attentively one could hear the sound of rushing water under foot. In many places there happened to be large fissures or holes in the ground, and the water could be seen rushing along on its subterranean course at a depth of about 3 or 4 feet from the surface. A large dam has been erected below this spring, and one of the most extensive sheep-washing establishments in the Colony is supplied with water by powerful engines from this dam. The whole area of the valley in which the spring arises does not exceed 2,000 acres, and the yield per annum at the rate quoted amounts to nearly eighty-five millions of gallons of water. There can be no doubt whatever that the source of this spring is far removed from the drainage area of the valley in which it occurs.

On Moredevil Station, near the source of Cox's Creek, many years ago, a well was sunk to a considerable depth. The exact depth I have been unable to ascertain, but believe it was about 80 feet. No sign of water was obtained before this level was reached, when, as the workmen broke through some hard rock, the water rushed in so rapidly that they were compelled to abandon their tools and make good their escape by means of a rope and windlass. In a few hours the well was filled to within 10 feet of the surface. Some years ago, as the well just described exhibited symptoms of caving in, another well was sunk about 80 yards easterly from the first. This well is 100 feet deep, and is situated higher on the slope by 4 or 5 feet than the first well. When the bottom was reached the water came as rapidly as on the first, and rose to within 4 feet of the surface, and on the following morning the first well had overflown, and a strong stream amounting to upwards of 300 gallons per hour was flowing from it. This has continued ever since, through all varieties of seasons, without cessation. I have obtained from Mr. Williams, the present manager of Moredevil, the following statement, which I cannot do better than give in his own words :—"I have measured the rate at which the water rises in both wells. The first is 6 feet × 6 feet, and I think 80 feet deep, and is situated within 20 yards of a spring, where as a rule the water is on the ground. This is the well which overflows. January 5th, took out 5 feet of water; rose 30 inches in 50 minutes. January 6th, took out 20 inches of water; took two hours to fill again. January 28th, took out 4 feet of water; rose 25 inches in 60 minutes. February 14th, took out 7 feet of water; rose 18 inches in 30 minutes. The above measurements were all made in fine weather. In rain, or in cloudy weather, the water rises very much faster. You will see that, after taking out about 2 feet of water, the water rises much more rapidly than it does at the higher level. This is the case with both wells, as you will perceive by the following: No. 2 well, 10 feet × 8 feet, about 100 feet deep, situated about 80 yards from the spring, and the same distance from the spring, in an easterly direction from both. The water in this well stands about 4 feet below the water in well No. 1. South of this, about 20 yards, limestone is on the surface, and the ground rises gradually. On the lower ground below both wells, pipeclay is, I may say, on the surface; the depth to which it extends I don't know, but it is several feet. Water rises as follows: January 5th, took out 2 feet of water; the first 13 inches rose in 1 hour and 45 minutes; then 2 inches in 60 minutes; the remaining 9 inches at the rate of 1 inch per hour. January 8th, took out 1 foot of water; rose 1 inch per hour."

I have given Mr. Williams' statement exactly as it is written, and its value as a record cannot be doubted. My labours would have been considerably lessened, the results expedited, and my facts enhanced in value, had all the persons to whom I applied for information been as obliging as the late manager at Bando, and the managers of Bomera, Moredevil, and Trinkay. To those gentlemen my best thanks are due for the information they so promptly afforded.

It appeared strange to me that the weather should so much affect these wells and springs; and in turning the matter over in my mind I thought I had discovered the solution in the fact that on bright sunny days the trees must evaporate an enormous quantity of moisture, which upon dull days would be retained or rather not drawn from the earth. In the case of the springs at Tambar and Garrawilla, which must have their fountain-head far distant from where they appear, and the wells of which Mr. Williams gives the description, a little reflection will show that the cause of this alteration in the outflow cannot be ascribed to the influence of the vegetation. The springs at Tambar are on the side of a mountain, and 300 feet from the summit; and the springs in the wells at Moredevil are found at depths respectively of 80 feet and 100 feet, a depth to which no ordinary roots would penetrate.

Coomoo Coomoo is a station situated upon a creek of the same name, and there are a few remarkable wells upon it, which unfortunately I have not been able to fix upon the map. Near the head station there are two wells on the creek about 10 feet above its bed, and the water rises in each to within a foot or two of the top. The creek is often dry. Lower down there is another well, not far from the same watercourse, which makes water at the rate of nearly 7,000 gallons per hour. Coomoo Coomoo Creek, as will be observed by the map, flows out on the plain, and in wet seasons forms Goran Lake, a sheet of water some 25 to 30 miles round. This lake, which comes into existence during very wet seasons, and sometimes lasts for several years, forms in what appears to be a depression in the plain, the borders of which are markedly defined by a ridge of sand. The depth of the water varies from 3 to 7 feet. Several miles to the south-west, Trinkay scrub, celebrated for its ironbark forest, is situated. The soil is of a loose, sandy character, and almost anywhere in the scrub good water can be obtained at a depth of from 13 to 20 feet. Its elevation is 50 to 60 feet above the lake, but the water held in reserve in the scrub never finds its way to the lake, as wells have been sunk between the two without finding water in any considerable quantity.

The well numbered 59 on the plan is situated on Wondoobah, and as will be seen by the Schedule flows over the surface. It is sunk at the base of a conical isolated hill, to a depth of about 60 feet, and at an elevation above the level of the plain of 120 feet. It has continued to flow for fourteen or fifteen years. Well No. 57 on the plan is about 5 miles from No. 59, in a direct line between the latter and the plain, and about 100 feet lower. This well is described as follows :—"6 feet by 4 feet; first 100 feet red soil, with gravel layers containing fossilized bones; teeth of diprotodon found at 100 feet; from 100 feet to 150 feet all red clay; then 3 feet of drift containing little fresh water; 3 feet of clay same character, then boulders and gravel; 3 feet of whitish clay strata dipping slightly to the west." The total depth of this well is 159 feet, and as the surface is 100 feet lower than well No. 59 this would place the bottom 259 feet below the level of the flowing well above described.

With regard to the possibility of finding brackish or salt water passing through it, and then obtaining a supply of fresh, my informants generally assert that instances have come within their knowledge of such cases. Well No. 86 (which is marked upon the plan, although it is in the county of Buckland) affords a remarkably good illustration of this. The description shortly is as follows :—"90 feet deep; at 50 feet salt water came in large quantities; at 90 feet unlimited supply of perfectly pure water in 5 feet of sand." Well No. 68 on plan is another illustration of the same experience. The description given me is :—"Size of well, 7 feet 6 inches by 7 feet 6 inches; 41 feet deep; 6 feet of black soil; 9 feet blue clay; 17 feet whitish clay and gravel; 7 feet of sand; 2 feet loose water-worn stones and sand mixed; first water at 25 feet, in clay and gravel; supply limited; quality hard and brackish; water at bottom fresh; supply abundant." I have no information of instances of the reverse, *i.e.*, fresh water being found first and brackish afterwards, and most likely for the reason that as soon as fresh water is struck well-sinking ceases.

The watershed and general appearance of the country is about the same for the Mooki River and Cox's Creek. The plains extend some 30 miles from one to the other past Lake Goran, but in other places the fall is sharply defined by low scrubby ranges and abrupt basaltic mountains. The plains on each are generally the same loose black soil, in moderate and good seasons producing an abundant and luxurious vegetation. With twenty-five wells on the western watershed of the Mooki, I find the average depth to be 46½ feet, and the average depth of water in each well 13¼ feet. In forty wells on the eastern watershed of Cox's Creek, extending over nearly 70 miles, I find the following averages: Depth of well, 70 feet; depth of water in well, 18 feet. The average of twenty-four wells on the western watershed of Cox's Creek is as follows: Depth of well, 62 feet; depth of water in each well, 22 feet. I may here mention that west of Cox's Creek, at a distance of 10 miles or less, loose sandy soil is encountered, and water, I am credibly informed, can be obtained almost anywhere at from 10 to 20 feet from the surface. A sandstone formation extends to the Castlereagh, and is covered with perhaps the grandest ironbark forest in the Colonies. Of the eighty-nine wells situated on the western watershed of the Mooki and the eastern and western watersheds of Cox's Creek, the average depth is 63 feet 6 inches, and the depth of water for each well is 17 feet 6 inches. From one end to the other along Cox's Creek an unlimited supply of good water may be obtained at an average depth of 50 feet. Of the eighty-nine wells of which I have spoken as lying on the watershed of Cox's Creek and the Mooki, I find that seventy-three bottomed in sand or gravel with an abundance of good fresh water; six bottomed in clay, with water brackish or salt;

eight on rock with hard water to brackish; one in sand, with water bitter; and one in rock, with water good. The average depth of these last sixteen wells I find to be 90 feet; three of them reaching the depth of 170, 159, and 130 feet respectively. It will be observed from these facts that water may be obtained at a moderate depth in sand or gravel almost anywhere in the county of Pottinger. Of course I am aware that the information I have been able to collect is only a small drop in the bucket of knowledge required before generalization can be indulged in. If, however, I am right in believing that Liverpool Plains bear a close similarity to all other of the great plains of the interior, it would be fair to assume that whatever may be successfully accomplished here may also be reached in other districts.

The methods adopted for drawing water from many of these wells, even at the present day, are in many instances of the most primitive kind. An implement known by the name of a "whip" is not infrequently used; a long pole fastened midway in an upright forked stick, and with a weight attached to one end and a bucket to the other, suspended over the well. By pulling upon the rope the bucket is lowered into the water, and then releasing it, the weight on the opposite end of the pole serves to elevate the water. Many thousands of sheep are watered in this manner. Signs, however, of an awakening to the benefits of civilization are becoming apparent; and on three or four stations wind-engines are already erected and doing good work.

Of the economic value of wells so large as those generally sunk I entertain grave doubts. The only benefit that I can see to be derived from a large well is where the vein of water is weak and a large soakage surface is required; where, however, as in most of the wells of this district, the supply of water is inexhaustible, the superior value of a small well properly tubed would soon be manifested. I have very little doubt that with boring machines, wells 16 inches in diameter could be made (and at one-tenth the cost) which would supply the place of any of the large wells. In most good wells the water shows a tendency to rise to the surface, and in some cases does actually rise and flow over. If wells were bored and tubed so that the water if it did rise could not escape through layers of sand or the fissures in the various strata, the chances of having flowing wells would be considerably increased. At any rate, in attempting to solve the problem, "Where does our rainfall go?" boring machines must be called into requisition, and it may happen, when our store of general knowledge has been added to by information similar to that which I have endeavoured to place before this Society to-night, collected from all parts of the Colony, the vast interior plains about the Darling may be rendered as profitable and productive as any other of the more favoured portions of this great land. Lieutenant Maury, in his celebrated work on "Oceanic Currents," begins with the startling sentence, "There is a river in the ocean." It may fall to the lot of some member of our Royal Society to exclaim at no distant date, "There are rivers in the earth," and, with the assistance of those who are in a position to render it, to indicate their locality, the depth at which they may be found, and how rendered serviceable to mankind.

POSTSCRIPT.—The map which accompanies this paper has been kindly prepared by Messrs. Goodwin, Licensed Surveyor, and A. P. D. Hamilton, Land Agent; its accuracy may therefore be relied upon.

SCHEDULE.

No. on Plan.	Size.	Depth to water.	Depth of water.	Total depth	General particulars.
1	..	..	6	6	Bomera Station; in sand; 6 ft. deep, with an unlimited supply; surface undulating.
2	..	54	24	78	Black soil flat; black soil 8 ft.; red soil, 10 ft.; 6 ft. blue rock; water 6 ft from top of rock; short supply.
3	..	10	10	29	Black soil flat close to creek; black soil 4 ft.; red soil 15 ft.; gravel 10 ft.; water in gravel, abundant.
4	..	8	10	18	Red soil flat; red soil 10 ft.; gravel 8 ft.; good supply; water in gravel, abundant.
5	..	62	20	82	Red soil; Appletree Flat; 77 ft. red soil; 4 ft. 8 in. sand; water in sand, inexhaustible.
6	..	68	15	83	Red soil; 78 ft. red soil; 4 ft. 6 in sand; plentiful supply, fresh water
7	..	12	10	22	Black soil flat near Bundella Creek; black soil 6 ft.; red clay 10 ft.; cemented gravel and large boulders 6 ft.; plenty.
8	..	15	10	25	Red soil, Appletree Flat, red soil 8 ft.; clay 10 ft.; cemented gravel and boulders, very hard, 7 ft; inexhaustible.
9	..	37	20	57	Box flat, red soil close to Tamilies Creek; red soil 20 feet; yellow clay 10 feet; cemented gravel 9 ft.; abundant supply.
10	..	12	10	22	Black soil, box flat; black soil 10 ft.; red clay 10 ft.; cemented gravel 5 ft. 6 in.; good supply, fresh water.
10A	..	23	7	30	Black soil flat; black soil 6 ft.; red soil 6 ft.; cemented gravel and boulders, very hard, 10 ft.; abundant water.
10B	..	23	7	30	Box flat; red soil 20 feet; clay 10 ft.; cemented gravel 9 ft.; good supply, fresh water
11	..	30	4	34	Black soil plain; black soil 5 ft.; red soil 25 ft.; gravel 4 ft.; plentiful supply fresh water.
12	..	29	3	32	Black soil plain; black soil 5 ft.; red soil 24 ft.; gravel 3 ft; plentiful supply, excellent water.
13	..	40	30	70	Edge of black soil plain; red soil 30 ft.; sandstone rock 40 ft. into gravel; plentiful supply, excellent water.
14	..	10	10	20	In bed of Coxe's Creek; sand 20 ft.; excellent water, grand supply.
15	..	35	40	75	In watercourse of Coxe's Creek; strata unknown; water in sand, excellent quality, good supply.
16	..	55	20	75	Black soil, old watercourse; strata unknown; water in gravel; will water 10,000 sheep; excellent and unlimited.
17	..	4	77	81	Level plain; stiff black soil 4½ ft.; gritty sand 5 in.; reddish soil 29 ft.; sand 20 in.; 51 ft. clayey marl; water in gravel; good; at 80 ft. found kangaroo bones and bivalve shells.
18	..	31	2	33	Level plain; sandy loam 31 feet; pure sand 2 ft.; water like sea-water; mineral smell disappearing on exposure to air.
19	..	55	20	75	Black soil, on edge of lagoon; strata not known; excellent water, unlimited supply.
20	..	..	90	90	Pipeclay at surface; strata unknown; overflowed thirteen or fourteen years ago in consequence of ringbarking.
21	..	65	5	70	Even surface; clayey black soil; strata unknown; water slightly hard, came in rock.
22	..	15	15	30	Undulating surface; stony black soil; quality of water fair, came in stones and gravel.
23	..	22	36	58	Level surface; black soil; plenty of water; slightly hard; came in clay and gravel.
24	..	80	8	88	Black soil plain; black soil 6 ft.; loam 24 ft.; 8 ft. pure sand; quantity unlimited, quality excellent.
25	..	55	15	70	Black soil, myall country; black soil 15 ft.; hard blue rock 65 ft.; water not abundant or good.
26	..	45	15	60	Open plains; black soil 55 ft.; 5 ft. sand; water fresh; supply unlimited.
27	..	55	15	70	Open black soil plains; black and red soil 70 ft.; sand 5 ft.; supply inexhaustible.
28	..	55	15	70	Same as last.
29	..	55	15	70	Same as last.
30	..	55	12	67	Black soil plain; black soil 67 ft.; bottomed in soft sandstone rock; supply excellent
31	..	60	20	80	Black soil 70 ft.; soft sandstone 10 ft.; from top of sandstone water supply excellent.
32	..	55	15	70	Same as 27.
33	..	55	15	70	Same as 27.
34	..	116	14	130	Black soil 130 ft.; reddish clay 10 ft.; supply limited and not good.
35	..	60	10	70	Black soil 60 ft.; drift 10 ft.; water supply not very good.
36	..	50	20	70	Open plain; black soil 40 ft.; sand 10 ft.; supply excellent.
37	..	60	10	70	Ironbark country; black soil 65 ft.; sand 5 ft.; supply excellent.
38	..	60	10	70	Same as 37.
39	..	55	15	70	Same as 37.
40	..	2	8	10	In sandstone country; sand 10 ft.; water supply inexhaustible, quality excellent.
41	..	55	15	70	Exactly similar to 27.
42	..	55	15	70	Exactly similar to 27.
43	..	51	15	66	
44	..	40	20	60	
45	..	40	20	60	
46	..	55	15	60	
47	..	51	14	65	
48	..	55	15	60	
49	..	70	10	80	Edge of open plains; black soil 50 ft.; rock 10 ft; clay, gravel interspersed 15 ft.; sand 5 ft.; water rose 60 ft.
50	..	125	5	130	Edge of plain; reddish clay; strata unknown; water supply not good.
51	..	50	14	64	
52	..	50	10	60	Plain; 16 ft. black soil; 1 ft. red sand; 5 ft. black soil; 1 ft. 6 in. red sand; 12 ft. black soil; 20 ft. flint and rotten sandstone with layers of clay; water slightly brackish; improving.
53	..	80	20	100	Open black soil plain; water in sand; supply unlimited.
54	..	160	10	170	On island of timber in plain; light red soil 10 ft.; hard blue rock 160 ft.; water supply not good; through joints of rock.
55	.	94	10	104	Forest country; clay 60 ft.; 30 ft. decomposed schistose rock; 2 ft. lignite; 50 ft. basaltic rock; spring in veins of hard bluish rock; limited.
56		90	10	100	Forest country; red soil; clay interspersed with drift sand 100 ft.; 10 ft. of water, very bitter, in fine drift sand and clay; improves with use.
57	.	147	12	159	Box forest; 100 ft. red clay and gravel layers containing fossilized bones; teeth of Diprotodon at 100 ft.; 50 ft. red clay; 3 ft. drift with fresh water; 3 ft. clay and then 3 ft. whitish clay and boulders.
58	..		60	60	Black soil; 120 ft. above level of plain; strata unknown, black soil and clay and then gravel and boulders; water flows over top of well; very good.
59	..	..	30	30	Stony forest; strata unknown; well 30 ft. deep with 30 ft. of water; came in slate, and larger supply in gravel.
60	..	41	30	71	Black soil; 7 ft. black soil; 64 ft. rotten rock, hardening as sinking proceeded; excellent and good supply of water; came through fissure in rock.
61	..	110	10	120	Light gravelly soil; strata unknown; limited supply brackish water, unfit for human use; stock drink it warily.
62	.	77	10	87	Black soil plain, 76 ft black soil, traces of lime and bones; 3 ft. gravel; 8 ft. limestone and gravel with water; water good, about 5,000 gallons in twenty-four hours.

No. on Plan.	Size.	Depth to water.	Depth of water.	Total depth.	General particulars.
63	..	16	24	40	Limestone formation, 12 ft. loose soil ; 4 ft. limestone boulders ; water good ; not a strong spring in gravel and boulders.
64	..	44	3	47	Black soil, old watercourse ; 32 ft. black soil ; 10 ft. reddish clay ; 3 ft. stones and boulders ; water in boulders and gravel, limited.
65	.	..	..	57	Old watercourse ; 12 ft. black soil ; 20 ft. jointy blue rock ; 25 ft. hardrock ; small stream in jointy rock ; no water at bottom.
66	..	85	51	136	Black soil 1 mile from a mountain ; 40 ft. black soil ; 10 ft. stones and gravel ; 30 ft. red soil ; 5 ft. cement ; 51 ft. limestone boulders and gravel, water in these
67	..	84	6	90	Open downs ; limestone and red soil 84 ft. ; brackish water ; (several wells have been sunk around this, all as salt as the sea) near Lake Govan.
68	..	25	16	41	Open plain ; 6 ft. black soil ; 9 ft. blue clay ; 17 ft. whitish clay and gravel ; 7 ft. sand ; 2 ft. waterworn stone and sand ; first water brackish at 25 ft. ; water at bottom excellent.
69	..	20	5	25	Open plain ; 9 ft. alluvial black soil ; 6 ft. blue clay ; 10 ft. sand ; water fresh, abundant.
70	..	28	12	40	Open plain ; 12 ft alluvial black soil ; 16 ft. whitish clay and gravel ; 12 ft. of sand ; water fresh and abundant.
71	..	19	5	24	Rich black soil plain ; 10 ft. black soil ; 14 ft. sand ; rock at bottom ; water in sand, unlimited.
72	..	40	1	41	Open plain ; 12 ft. black soil ; 28 ft yellow clay ; 1 ft. sand ; first water in sand salty, now good.
73	..	21	18	39	Rich black soil plain ; 10 ft. black soil ; 11 ft. sand ; water at 21 ft. slightly brackish ; 18 ft. fine drift sand ; water abundant, fresh.
74	..	22	8	30	Rich black soil plain ; 12 ft. black soil ; 10 ft. whitish clay and gravel ; 8 ft. sand ; water in sand ; fresh, supply abundant.
75	..	24	13	39	Open rich plain ; 10 ft. alluvial black soil ; 12 ft. whitish clay and gravel ; 15 ft. sand ; first water in sand ; fresh, supply abundant.
76	..	15	8	23	Rich open plain ; 10 ft. black soil ; 15 ft. sand and mussel shells ; 1 ft. red clay ; water very salt and bitter.
77	..	41	11	52	Box and rosewood forest ; alluvial soil loam 4 ft. ; 20 ft. red clay and gravel ; 10 ft. sand ; 11 ft. drift and gravel ; 1 ft. red clay , water very salt and bitter.
78	..	25	1	26	Rich black soil plain ; 10 ft. black soil ; 15 ft. sand and mussel shells ; 1 ft. red clay ; water very salt and bitter.
79	..	29	9	38	Rich open plain ; 9 ft. black soil ; 18 ft. whitish clay and gravel ; 9 ft. sand ; water abundant.
80	..	24	4	28	Rich black soil plain ; 2 ft. black soil ; 12 ft. whitish clay and gravel ; 4 ft. sand ; water in sand, fresh and abundant.
81	..	35	25	60	Open plain ; loam 50 ft. ; drift 10 ft. ; water abundant.
82	..	35	25	60	Open plain ; loam 45 ft. ; drift 15 ft. ; 25 ft. fresh good water.
83	..	35	25	60	Open plain ; 45 ft. loam ; 5 ft. drift , 25 ft. fresh good water.
84	..	35	5	40	Open plain ; 40 ft. loam ; no sand ; water not plentiful.
85	..	30	5	35	Open plains ; 35 ft. loam ; no sand ; water not plentiful.
86	County Buckland.				Myall timber ; 50 ft. reddish clay ; large supply salt water ; 35 ft. clay and gravel ; 5 ft. sand ; inexhaustible supply, fresh water.
87	..	..	.	..	Black soil plain ; black soil 5 ft. ; yellow clay and sand 40 ft. ; sand 4 ft. ; 30 ft. clay ; 8 ft. sand ; water inexhaustible.
88	..	..	..	..	Box timber ; lime, sand, gravel, 5 ft. ; water abundant.
89	..	..	..	.	(In county of Nandewar.)
90	..	.	..	..	Near Dividing Range, Coxe's and Borah Creeks ; about 40 ft. deep ; water supply in sand, abundant.
91	..	..	..	..	On plain ; black soil ; gravel ; sand ; strata unknown ; water inexhaustible, in gravel and sand.
92	..	..	..	..	Box and yellow-jacket forest ; black soil 14 ft. ; gravel 11 ft. ; water inexhaustible.
93	..	..	.	..	Box forest between ridges ; crystal quartz ; limestone ; bluestone ; strata unknown ; water at 20 ft.
94	..	..	..	..	On southern slope of box ridges ; strata unknown ; water in gravel and rock, rose to within 10 ft of surface.

Index to Wells shown on Map, Appendix L 3.

Number of Well.	County.	Parish.	Name of Run.	Depth of Well.	Size of Well.	Water struck at feet from surface.	Water stands at feet from surface.	Yield per day in gallons.	Quality.	Height above sea.	Nature of surrounding Country.	Strata.	Remarks.
				ft.	ft.								
1	Arrawatta	.....	King's Plains	70	5½ x 5½	65	65	Never-failing	Brackish	.....	N., granite ridges; E., S., and W., ridges and plain.	Black soil, granite, rotten slaty bottom	This well is only used in time of drought.
2	„	.....	„	90	8 x 4	.....	9	„	„	.....	Forest, plain, and ridges, chiefly white gum timber.	Black soil, rotten granite and pipeclay	Water stands 5′ from the top in wet seasons.
3	„	.....	Swamp Oak	45	6 x 4	.....	21	„	„	.....	N., barren ridges; E. and W., do.; S., forest and ridge.	Top brown soil, then basalt to bottom.	
4	„	.....	„	40	6 x 4	.....	4	„	„	.....	.....	.....	In a wet season overflows.
5	„	.....	Byron	21	4 x 4	20	15	„	Slightly brackish	.....	Black soil plains and open forest country	Black soil 15′, basalt 6′.	
6	Macquarie	.....	Cutarbat	50	Circumference 8	.....	25	.....	Fresh and hard	.....	Undulating, ridges running into rocky mountains.	Black alluvial soil, pipeclay, and slate rock	The well is believed to be down to the level of river water. The water is hard, but used for household purposes.
7	„	.....	Huntington	101	Circumferenee 8	.....	71	.....	Hard	.....	Low ranges, with creeks running to river	Soft slaty rock	Sunk on a low ridge believed to be down to level of river water, used for household purposes.
8	Manara	.....	Kilfera	189	5 x 2½	80	80	50,000	Good stock	.....	Salt bush plains, lignum, S. side	.....	Salt at 80′; got much better as we went deeper; last spring struck almost fresh, 100′ open shaft, 89′ bore, 3½″ diameter.
9	„	.....	„	162	5 x 2½	50	60	Unlimited	Salt	.....	„ „ „	Gypsum, sandstone, and clay	Salt at 50′; improved slightly when bored; open shaft 100′, bore 62′.
10	Franklin	.....	Moolbong	110	6 x 3	.....	100	20,000	Good and fresh	.....	Salt and cotton bush, dark clayey soil	Alluvial	Selection of site for well a matter of chance in some parts of Riverina. Good stock water is obtained at a depth of 100′ to 130′; in other parts two wells within 1 mile of each other salt water was obtained; midway between, another shaft was put down and good water obtained.
11	„	.....	„	250	.....	115 & 250	.....	Unlimited	Fresh	.....	„ „ „	„	
12	Windeyer	.....	Buckalow	150	6 x 4	130	110	24,000	Slightly brackish	.....	Broken plains	Alluvial, 120′ pipeclay and drift 30′	This well is in a sandy box swamp, and gives one of the best supplies in the district; other shafts have been tried in the Mulga country and failed to strike water; two of them sunk 220′.
13	Taila	.....	Mallee Cliff	70	5 x 3	.....	.....	.....	.....	.....	S., mallee and porcupine grass; W., N., and E., black oak.	Loamy soil 15′, drift sand 55′.	
14	„	.....	„	18	5 x 3½	15	12	3,000	Slightly brackish	.....	Pine ridges, mallee, porcupine grass, and salt bush.	.....	This well is covered by the Murray water when in flood.
15	„	.....	Bedura										
16	Wentworth	.....	Gall Gall										
17, 18, 19	Taila	.....	O. B. Turlee										
20	Wentworth	.....	Gall Gall, C.								Red sandy soil or clay on salt-bush plains		One well on Gall Gall, C, we pumped for a considerable time in the summer, hoping the water would improve, but it did not do so. Have several soakage wells, with good stock water, all at shallow depths of not more than 20′, all sunk in the beds of dry creeks where the flood waters back up, and all within 5 miles of the river; the supply is not good, and are only made useful by making large chambers and drives at bottom of shaft.
21, 22	„	.....	West Parengi, A.	75 to 150	.....	.....	.....	.....	Salt	.....	Red sandy soil in belar or oak scrub	.....	
23 to 27	„	.....	Wamberrar								Red sandhills in mallee		
28 to 34	„	.....	Outer Tapio								Red clayey soil in box flats		
35 to 37	„	.....	Outer Tilato								White clay flats, with box timber		
38	Menindie	.....	Burta	280	6 x 3	250	250	Not tested	Good stock	.....	Salt and cotton bush, light scrub, and undulating.	Hard clay, with gravel 100′, alluvial 80′, pipeclay and mica 30′, soft sandstone rock and clay 70′.	Open shaft 200′, bore 80′. This well is to be sunk to full depth of bore, when the supply is expected to increase. A Tiffen borer was used.
39	Windeyer	.....	Mallara	64	6 x 3	64	20	„	Salt and poisonous	.....	Sandhills and oak ridges, like decomposed limestone.	Pipeclay and drift	A good many trial shafts have been sunk on this run, salt water being struck in drift under 100′ in all of them.
40	Perry	.....	Moorara	100	6 x 3	82	82	17,500	Good stock	.....	Open salt and cotton bush plains, with oak clumps, &c.	Alluvial 82′, fine drift 18′	Have sunk fifty trial shafts on different parts of run, from 80′ to 100′; salt water struck in all; unfit for use.
41	„	.....	Pan Ban	100	6 x 3	80	80	Unlimited	Fair stock	.....	Open salt bush plains, with oak ridges, &c.	Clay throughout	50,000 gallons per day have been obtained, but the supply seems practically inexhaustible; slightly brackish.
42	„	.....	North Pan Ban	78	6 x 3	78	75	8,000	„	.....	„ „ „	Alluvial 20′, fine drift 58′	Cool, cloudy weather seems to increase the supply.
43	Rankin	.....	Barnato	150	6 x 3	135	135	5,000	Good stock—Slightly sweet.	.....	Sandstone ridges; red clay flats; mulga pine; beefwood.	Alluvial gravel, cement and sandstone rock	There is a 30′ drive in this well.
44	„	.....	„	200	6 x 3	190	140	7,000	Good stock	.....	Pine sandhill; mulga and belar ridges	Gravel and cement 100′, sandstone 60′, cement and blue clay 40′.	There is a 30′ drive in this well.
45	Woore	.....	Fulham	175	5 x 2½	169	168	3,296	„	.....	Loamy flats, rocky ridge, and mallee sandhills.	Loam, clay, and cement 167′, drift 8′	8 miles from this well a trial shaft was sunk 188′; no water struck; half-mile from the above well a shaft 6′ × 3′ was sunk to a depth of 96′. Then a bore 130′ = 226′, no water being struck; boring still going on.
46	„	.....	Moama	170	6 x 3	170	.....	3,000	Very brackish	.....	Box flats and pine sandhills	Alluvial 100′, sandstone flags 70′, water in blue clay.	
47	„	.....	Baden Park	200	6 x 3	.....	.....	6,000	Good stock	.....	Red clay flats and pine sandhills	Cement and sandstone.	
48	„	.....	Emerald	140	6 x 3	126	.....	.....	„	.....	Open mulga, with ridges of mallee	Hard sandstone 69′, chalk 1′, hard sandstone 70′.	The sandstone rock in this well required to be blasted; it is intended to put a drive in this well to increase the supply.
49	Booroondara	.....	Paddington	200	8 x 4	.....	.....	5,000	Brackish	.....	Ironstone rises; box flats; mulga, &c.	Alluvial pipeclay, cement, and sandstone rock.	
50	Woore	.....	Warfield	220	6 x 3	.....	.....	6,000	Good stock	.....	Red flats and pine sandhills	Pipeclay and cement, hard sandstone.	
51	Blaxland	.....	Bedooba	300	.....	300	115	.....	Good and fresh	.....	Undulating	Blue slate	This well was sunk before present owners bought station. There are two long drives at bottom, not required for use.
52	Mouramba	.....	Priory	230	8 x 4	.....	.....	.....	Good stock	.....	Undulating yarren and box flats and ironstone rises.	Cement and hard sandstone, water in sandstone.	
53	Canbeligo	.....	Booroomugga	100	6 x 3½	.....	.....	.....	.....	.....	Undulating ridges; volcanic hills	Red clay 3′, red sandy drift 4′, coarse red drift 6′, red clay 7′, white sandy rock 10′, pipeclay 3′, white sandy rock 12′, fire-clay 4′, white sandy rock, with occasional thin strata of fire- and pipe-clay, 51′.	This well is not yet finished.
54	„	.....	Girilambone	155½	Bore	155	128	.....	Good stock	.....	.....	Hard sandstone, rock, cement, quartz, and gravel.	
55	„	.....	„	120	Bore	116	105	.....	Very salt	.....	.....	Quartz, gravel, and hard sandstone	A shaft put down here would make 6,000 gallons per day.
56	„	.....	„	100	Bore	.....	.....	.....	.....	.....	.....	Hard slate, quartz, and hard rock, &c.	
57	Ranken	.....	Donald's Plains A	160	6 x 3	.....	133	4,000	Fresh	.....	.....	Pipeclay and cement	This well is in the bed of Tiltagoona Creek.
58	.....	.....	Mount Manara	.....	.....	.....	.....	.....	.....	.....	.....	.....	Government well condemned as being unfit for stock. A well half a mile to the N. W., good water, supposed to be soakage.
59	Booroondara	.....	Donald's Plains I	90	4 x 2½	.....	.....	Limited	Fresh	.....	Cotton bush; mulga rises, and sandstone hills.	Pipeclay, cement, and layers of drift	This well has never been used for stock purposes, owing to a 10,000-yard tank full of water in the vicinity.
60	Cowper	.....	Coronga Peak	120	6 x 3	.....	.....	„	Good stock	.....	Undulating, red, volcanic hills, and mulga.	.....	Not required to be used.
61	Finch	.....	Goondoobline	50	6 x 6	35	35	Not tested	Fresh	.....	Sandy pine ridges, then open box flats	Sand.	
62	Leichhardt	.....	Polly Browan	20	6 x 5	18	10	1,000	Good and fresh	.....	Buthar and pine timbers, small clear patches of salt-bush.	White loose sand	This well was cleared out in the dry time, and it watered the whole of the stock on the place in the summer of 1881 and 1882.
63	Finch	.....	Gingie	25	7 x 7	20	20	Limited	Good	.....	Open, red and black soil	Sand	This well is a simple sand pocket, surrounded by clay, and catches the drainage of the adjacent hard ground; the supply is always limited, and if sunk too far salt water is struck.
64 to 78	Leichhardt	.....	Euroka	45 to 68	.....	.....	.....	.....	Saline	.....	.....	.....	Fifteen bores by machinery on various portions of this station struck water in each of the first sand-drifts met with; further attempts at finding fresh water abandoned.
79	Finch	.....	Dungalear	120	.....	100	80	.....	Salt, unfit for stock	.....	Very level, loamy soil	.....	The only fresh-water wells here are small sand wells, no springs being tapped; would do for household purposes, or (say) 1,000 sheep.
80 to 88	„	.....	„	20 to 40	.....	.....	.....	.....	Fresh	.....	.....	Sand	There are nine sand wells, with only a limited supply of splendid clear fresh water; not sufficient to water any large number of stock; might be made available by having a receiving tank kept full for use in troughing; they are soon pumped dry and take a considerable time to fill again; they are all in sand hollows, and fresh water is indicated by gum-trees growing in vicinity; if sunk too deep a clay bottom is struck, and continued through that for any distance salt water would be struck.

W. B. HENDERSON,
Superintendent of Drills.

APPENDIX L 5.

The Superintendent of Drills to The President of Royal Commission on Conservation of Water, &c.

Sir, Department of Mines, Diamond Drill Branch, Sydney, 30 October, 1884.

In submitting the various drawings and sections of boring-machines and connections other than diamond-drills, together with the accompanying voluminous evidence given in favour of each particular machine, I have the honor to submit also for your consideration the following remarks obtained by the practical working of most of the machines referred to in these drawings and sections.

The first and most important matter to be considered in the application of any particular class of boring-machine is its suitability for the class of work it is to undertake. To arrive at this, it is necessary to be practically acquainted with the nature of the country in which the work is situated. Without this knowledge, the best machines in the hands of the most perfect workmen may be placed in such a position as to prove a complete failure. There have been many instances of this having been experienced in Australia, and frequently the cause, when looked for after bitter experience, is found too late to be remedied.

Imported boring-machines of the supposed best make have been laid aside in this Colony, having been found totally unfitted, though introduced under the most glowing accounts of their performances elsewhere; in fact, there is great harm done to the best interests of the Colony and its most enterprising pioneers by unskilled non-practical advice, and having to depend mainly on the testimony obtained through trade pamphlets issued at the instance of the makers of machines foreign to the wants, stratas, and circumstances of Australia. Such testimonials generally give the exception—the best,—leaving out the failures, the accidents, the delays, and all the bad work. I have had borings carried out under my supervision in this Colony by boring machines (other than diamond drills), in which a depth of 103 feet was bored in twenty-six hours easily and well, more easy than as many inches in the same number of days could be effected by the same appliances in different strata. I have had rocks to contend with in the Colonies practically impenetrable to the ordinary steel percussive applied bit—rocks that I had to draw and sharp bits thirty odd times to penetrate 1 inch; swelling clays, which in the course of one night expanded so as to entirely close up a 6-inch diameter bore; gravel drifts forcing up through the boring-rods, and that, becoming jammed therein, had force sufficient to poise the whole plant off the surface—hanging so—feet in the air.

Swelling clays are the ordinary every-day circumstances, and there is no experience before given which cannot be overcome by practical work and selection of suitable appliances.

A boring-machine suitable for work in medium hard rocks is not suitable for swelling clays, drifts, or alluvial soils, and *vice versa*.

For alluvial soils, sand drifts, and swelling clays, common and peculiar to the western plains of this Colony, percussive motion alone, in my opinion, must prove a costly failure. In this class of country, distant from settlement and workshops, I have found that rotary cutting motion with steel cutters, and adapted to be worked by either horse or manual power, and requiring the least possible quantity of water, made of the best wrought iron or steel, so as to dispense with the objectionable castings so common to imported machines, will alone succeed.

Having arrived at this opinion, not only from personal experience in this Colony, but also from the undoubted and almost daily proofs in the adjacent Colonies, the selection of the best machine is simplified mainly by the consideration of those which are worked on the principle of rotary motion, and of which there are placed before you several varieties.

The most important question which next arises in connection with the use of the several classes of boring-machines is the quantity of water required to work them. In Australia the search for water underground is chiefly carried out in those districts where the supply of water on the surface is very limited—indeed, in some cases, barely sufficient to meet the domestic requirements of the men employed to work the machine. In such a case it becomes a matter of great importance to use the machine which requires the least quantity of water, for the machine which would require the power of an 8, 10, or 12-horse power boiler to work it would be useless in this class of country.

During the late severe drought, when, in order to economize the scarcity of the water supply, horse-power had been used in place of steam, I endeavoured to keep a small party employed at one of these machines, supplied with water by a team of eight horses; I was, however, compelled to fall back on manual labour to work the machine, as I found that the water had to be carried such a distance, the horses used as much water as they were able to draw. In circumstances such as these, it is practical acquaintance with the class of country, together with machine and tubing suitable to pierce swelling clays and drifts, that are likely to meet with success in searching for underground supplies of water, and not machines made in and suitable for foreign countries, worked by men strangers to the nature of country through which they will have to pass before reaching water.

Another matter, which must in all cases be taken into account, is the weight of the machine which is being forwarded to carry out the work, not only on account of the cost of carriage, but also in view of the danger which exists of the machinery becoming bogged *en route*.

As the country is at present, and with the means of transit at present available, it is absolutely necessary that these machines should be as light as possible, consistent with efficiency. The cost of carriage alone, for instance, of one of these machines last year, from one site to another, amounted to £300. This drawback can be rectified as far as possible by the adoption of water-augers made in Australia to suit the circumstances of the Colony and yet capable of attaining the required depths. It will be seen by the official returns which I have the honor to hand you, that the several Australian Colonies have gained considerable experience in this matter of boring for water.

In Victoria, 330 bores have been put down during the year 1883, by the Government alone, in search of water, being a total of 24,403 feet. In South Australia also, twenty bores, 5,479 feet, have been carried out for the same purpose; and in New South Wales, the boring machines under my supervision have put down, up to March last, forty bores, representing 4,516 feet, in twenty-five of which fresh water has been discovered. The discoveries of fresh water would, I believe, be found greater were the bores generally carried deeper, as will be seen by the section of those bores, which show that the salt water is discovered at a shallow depth, almost always above the fresh water.

I specially wish to invite your attention to the sections of several bores put down in the north-west of this Colony, and in the Warrego District, Queensland. I

I also desire to draw your attention to the system of telescoping, which has been adopted in this Colony for some years past, and which has proved to be so effective in shutting off salt or other impure water, as shown in the diagram which I have the honor to submit for your information. This method is so simple and so clearly shown by the diagram that it is needless for me to here explain it. This system has been found eminently successful, not only in combating with swelling clays or drifts as well as salt or impure water, but in giving increased facilities for not only attaining great depths and overcoming swelling clays and drifts, but it gives the proper outlet for the water to flow, or the insertion of deep well pumps, where natural laws require it to be so. The riveted boring-tubes imported from America, and which have been tried, were found to be an utter failure, so much so that large quantities of this class of tubing having been imported, had to be laid aside as useless. Tubes of a superior quality, prices of which I herewith annex, varying in diameter from 7 inches to 2½ inches, have been imported by this Government from Europe, and their success has been so marked that I believe the Governments of South Australia and Queensland are becoming large importers of this class of tubing for the bores being put down by their machines.

With reference to the rock formations, especially those of a hard nature, and where water is available, the diamond drill far surpasses any other kind of borer. The cost of a 6-inch or 9-inch diameter bore, put down by a diamond drill, would not be very much greater than the cost of a 3-inch diameter bore, which is the size commonly used. I beg to refer you to the cost of a bore, 3½ inches in diameter, which was put down 1,003 feet, under my supervision, on the Holt-Sutherland Estate, the whole expenditure from commencement to completion being only at the rate of 4s. 9d. per foot; the general average field cost per foot of boring by diamond drill for the whole year being at the rate of 10s. 3d. per foot.

I beg to hand you a report received by me relative to boring carried out in New Zealand. The borer referred to is that known as the Pennsylvania Oil-rig; an expert from America conducted the work. I reported on this subject last year, and I now respectfully draw your attention to this report and the latest performances.

I further hand a statement of the borings executed in three respective colonies, a table showing comparative cost and speed of the several waterboring-machines under my charge, put to the test in such a manner that there cannot exist a doubt as to which machine is best.

I am clearly of opinion, by the working of several class of borers, that Australian-made machines and workmen, with Australian bush practical experience, are the best means that can be adopted to develop the underground water supplies of these Colonies.

In conclusion, I may mention that there are at present at least five different engineering firms in these Colonies, makers of a variety of boring machines other than diamond drills, and I anticipate at no distant date that machines will be made by such firms capable of fully meeting all the circumstances I have pointed out.

I have, &c.,

W. B. HENDERSON,

Superintendent of Drills.

ARTESIAN TUBING.

APPENDIX L 7.

CONSENSUS of Reports on Water Supply received from various Mining and other Companies at Ballarat at dates as under, viz.:—

September 26th, 1884—From J. H. Thompson, Esq., Consulting Engineer to the Ballarat Company, Victoria.

AVERAGE quantity of water pumped (the body of water being at its maximum) was from 2,500 to 3,000 gallons per minute, or from 3,600,000 to 4,320,000 gallons per diem. This enormous supply was pumped steadily for over two and a half years without showing any signs of abatement; mine was at work for twelve years; main body of water did not decrease to any perceptible extent during the two and a half years it was contended with, but it was stopped back by a scheme he devised and put in operation (*vide* Report Chief Inspector of Mines, published in 1877, by the Department of Mines, Victoria, for the year 1876, pp. 9–10). Area of mine was 1,243 acres; shaft sunk to 570 feet; main body of water occurred at 360 feet, in the honeycombed basaltic formation, noted in that Colony for carrying large volume of water. Coursing water at time of leaving off work was about 800 gallons per minute, increasing and decreasing as the mine was opened up; average between 700 and 800 gallons per minute; mining operations were being carried on at some 1,000 feet from shaft when work was stopped; he acted as consulting engineer to a Company at Ararat, which had great difficulty in contending with water; maximum pumped, 4,000 gallons per minute, or 5,760,000 gallons per diem; since fallen off to 1,000 gallons per minute, and still likely to decrease; pumping in this instance was from shallow depth of 180 feet; geological formation of the country greatly affects the supply of water, as instanced that of the Duke Company, Timor, near Maryborough; pumping operations have been carried on for the last ten years; average quantity pumped during this time being about 3,000 gallons per minute; country subject to percolation, no doubt accounting for steady supply experienced.

25th September, 1884—From Robert Sharp, Esq., Ararat.

Maximum number of gallons pumped per day, 5,010,400; pumping has been continued for twelve months; present quantity per day, 1,060,400 gallons; mine has been at work three years; no perceptible increase takes place as more ground is opened up. Area of mine, 200 acres. In this locality the yearly rainfall increases our water. In the City of Ballarat Company, where he was formerly employed, the water in the basalt was tapped at 150 feet; after eight years' pumping the shaft was eventually sunk to 450 feet, when bottom of basalt was reached; water was then puddled back, and very little decrease took place until work was resumed in deep ground with basalt overhead, when, as the ground was opened, the water gradually increased every foot that was driven.

29th September, 1884—From Isaac Wheelden, Esq., Drummond-street, Ballarat, Victoria.

Average number of gallons pumped daily was 2,880,000; mine was at work eight years, water being pumped about six years; area of mine, 2½ × 3 miles square. An account of work done may be found in p. 479 of Gold-fields and Mineral Districts of Victoria, by R. B. Smyth.

10th October, 1884—From R. M. Sergeant, Esq., Manager, Band of Hope and Albion Consols (No Liability) Ballarat.

Area, about 1¼ mile long by ½ mile wide; 20,000 gallons of water per diem raised, during which the three shafts were connected with galleries below, and crossed the gutter in every direction, the water flowing freely for twenty years, but drained at the rate of about 2 per cent. per annum; have sunk 914 feet for purposes of quartz-mining, and found the water comparatively light, and not good for sanitary purposes.

13th October, 1884—From J. M. Mackay, Esq., Manager of the Duke Company, Ballarat, Victoria.

For twelve months 5,000,000 gallons per diem were raised from a depth of 350 feet; during the years 1881, 1882, 1883, and 1884, the volume, of water gradually eased, until, at the date of writing this, 2,650,000 gallons of water per diem were raised; area of mine, 293 acres 2 roods $3\frac{7}{10}$ perches; area worked, 140 acres; area actually taken out (say) 45 acres; area unworked, 153 acres.

W. B. HENDERSON.

TABULATED Statement of Water Supply, taken from Reports received from Mining and other Companies at Ballarat, Victoria, 1884:—

Name of Mine.	Area.	No. of gallons per diem.	No. of years pumping.	Water increasing or decreasing.	Nature of strata.	General remarks.
Band of Hope and Albion Consols, Ballarat.	About 1¼ mile long by ½ mile wide.	20,000 gallons ...	20 years.....	Decreased at the rate of 2 per cent per annum.	Basalt, with intervening drifts, and clays overlying schistoze slates.	
Duke Company, Ballarat.	293 acres 2 roods $3\frac{7}{10}$ perches.	2,650,000 gallons.	4 „	Decreasing at rate of 700 gallons per diem.	Silurian rock...	
City of Ballarat Water Supply Company.	1,243 acres	3,600,000 to 4,320,000 gallons.	2½ „	Stationary* ...	Honeycombed basaltic formation.	* Stopped back by a scheme suggested by the Consulting Engineer.
Grand Junction Ararat Company.	200 acres	(Maximum), 5,010,400 gallons; at present, 1,060,400 gallons.	1 year pumping; 3 years at work.	No perceptible increase excepting after rain-fall.	Not mentioned	
Great North-west Company, Ballarat.	2½ × 3 miles square.	2,880,000 gallons	6 years.....	Increasing.....	Basalt rock ...	

W. B. HENDERSON,
Superintendent of Drills.

APPENDIX L 8.

Mr. J. Rossiter to The Superintendent of Diamond Drills.

Dear Sir, Stockton Colliery, Newcastle, 28 October, 1884.

In answer to your inquiries of the 22nd instant, *re* operations and progress of the South Pacific Petroleum Company, Gisbourn, New Zealand, of which I have been a member of the Board of Directors during the said company's existence:

Boring operations by the above-named company were commenced in August, 1880, from which time up to March 31st, 1884, seven (7) bores were put down, ranging in depth from 100 to 375 feet, or in all about 1,330 feet, under a labour cost of £4,430, or £3 6s. 8d. per foot of bores, exclusive of plant, tubes, &c., the cost of which being £6,650, a very large amount for the work done, and with no other result than that of good indications.

Size of tubes, 8, 6, and 4½ inch, as used in American oil wells. Nature of country gone through, chiefly soft swelling clay, highly saturated and charged with petroleum, paraffine, and explosive gases, also intermixed with beds of loose sandstone boulders at various depths, which in most cases proved fatal to further progress.

All the bores as above, with most of the tubing, have from one cause or another been lost, except the 375-foot bore, which is still capable of being continued by the insertion of a 4½-inch tube.

Our plant consists of the ordinary percussion drill, &c., as used in most of the oil countries of America, which no doubt are worked to advantage in some situations and under some circumstances, but I am strongly of opinion that they are not all that is required in our case, and that we should be in a much better position had we in the first place adopted the diamond drill specially arranged in accordance with the nature of our requirements.

For your further information, I may mention that the Southern Cross Petroleum Company, situate about 40 miles from our works, have also expended a large amount of money with no better results, having lately lost their tools in a 730-feet bore.

Wishing you every success in your highly important undertakings, &c.,—

I remain, &c.,

JOHN ROSSITER,
Mechanical and Mining Engineer.

APPENDIX O 1.

The Superintendent of Drills to The Under Secretary for Mines.

Sir, Department of Mines, Diamond Drill Branch, Sydney, 25 October, 1884.

In submitting, for the information of the Honorable the Minister, the enclosed returns relative to the diamond drills and other boring machines employed in the Colonies of Victoria, South Australia, Tasmania, and New Zealand, as supplied by the respective Governments of these Colonies, I have the honor to annex a comparative statement of the working of diamond drills in the adjacent Colonies of Victoria and South Australia (as taken from returns), and of the working of the diamond drills in this Colony.

The returns furnished by the other Colonies are so incomplete that no comparison could be made. With respect to the boring machines (other than diamond drills), the information supplied is of such a nature that it is impossible to make a comparison between any of the Colonies, with the exception of the working cost per foot, which in South Australia amounted to £3 1s. 6d.,* whilst in this Colony it was only 19s. 8d. per foot for the work done during the year 1883.

I desire particularly to invite the attention of the Honorable the Minister to the tabulated statement herewith annexed, which has been prepared from the information supplied by the Government of South Australia, showing the amount of work done and the cost thereof of boring machines in that Colony.

I have, &c.,
W. B. HENDERSON,
Superintendent of Drills.

* Note (*on revision*):—I find this sum should be £3 8s. 8d.—W.B.H., 20/6/85.

COMPARATIVE Statement relative to Diamond Drills in the Colonies of Victoria, South Australia, and New South Wales.

Colony.	No. of machines.	Cost of same.	Cost of working.	Total.	No. of feet bored.	Rate per foot.
		£ s. d.	£ s. d.	£ s. d.	feet	s. d.

NOTE.—Besides the above, 403 feet 6 inches have been bored, the cost of which is not given.

APPENDIX O 2.

APPENDIX O 2.

Particulars of Boring done by Mr. Bignall, at Warrigul.

At No. 1 bore-shaft sunk to rock, depth 60 feet; bored with drill 150 feet; struck water in fine drift; water rising to within 40 feet of surface; supply equal to 30,000 sheep daily; water lifted by means of windmill and No. 5 Blake's pump, worked by 8-horse power steam-engine.

No. 2 bore-shaft sunk to well, depth 46 feet; bored with drill 171 feet 8 inches; struck water in fine drift; water rises to within 40 feet of surface; supply equal to 25,000 to 30,000 sheep; tested with pump and engine when complete; four days working without lowering water in bore; pump throwing 2,500 gallons per hour.

No. 3 bore put down 218 feet; struck large supply of brackish water; intend tubing and boring to fresh water; have rods and tubes equal to 1,500 feet.

Besides these wells, there are two others sunk by hand labour to a depth of 35 feet and 169 feet respectively, both of which give a good supply of fresh water. It is the intention of the proprietors to put down two more wells, one of which is in course of excavation. These will make the water supply of station equal to all requirements.

APPENDIX O 3.

STATEMENT showing the cost price, working cost, time occupied, depth bored, and cost per foot of the Boring-machines employed by the Government of New South Wales in search of water, to November 1st, 1884.

Description of machine.	Cost of each set of machinery.	Total cost of machinery.	Working cost, exclusive of machinery and transport.	Total working cost, exclusive of machinery and transport. * Part of the work at this bore was done by prison labour, which is not included here.

NOTE.—Other bores to the depth of 1,128 feet 5 inches, costing the Department 7s. 9½d. per foot, were also put down; but as part of the labour was supplied by those persons engaging the augers, no reliable returns for the whole work can be given.

Department of Mines,
Diamond Drill Branch.

W. B. HENDERSON,
Superintendent of Drills.

APPENDIX O 4.

COMPARATIVE Statement of the cost of and work done by the Australian and Tiffin Water Augers to 31st March, 1884.

Number of machine.	Name of machine.	Cost of machinery, including tools.	Depth of borings.	Expenditure for tools and repairs for this boring.	Average daily borings.
		£ s. d.	ft. in.	£ s. d.	
8	Australian Water Auger	1,277 8 7	1,503 10	206 5 7	In proportion as 1·25 is to 1·00.
6	Tiffin Water Auger	1,661 15 0	1,765 2	1,356 15 6	

WM. B. HENDERSON,
Superintendent of Drills.

Department of Mines, Diamond Drill Branch,
Sydney, 29th September, 1884.

APPENDIX Q 1.

Mr. R. C. Webb to The President.

Dear Sir, Kilfera, Ivanhoe, N.S.W., 22 December, 1884.

When giving evidence before you on the 4th instant, I omitted to mention that the round tanks (sketch enclosed) are my favourite tanks, and much the best for stock.

Contractors have a dislike to tackle them at first, but once they have done one they will do them for the same price as the ordinary square ones.

When these tanks are made where the country is quite flat, I would advise the earth taken out to be put in form of bank all round excavation, but in no case to be nearer to edge of hole than 66 feet. In many cases the earth removed would be used in form of dam.

Yours faithfully,
R. C. WEBB.

APPENDIX Q 2.

THE average depth of the wells to first water is 100 feet. We generally bore another 50 or 100 feet for a supply, but in no case have we got fresh water.

R. C. WEBB.

APPENDIX S.

APPENDIX S.

Mr. William Farrer to The President.

Sir, Thuraby, Newtown, 21 January, 1885.

I would wish to supplement the evidence that I gave before you on Thursday last, January 15th, in regard to matters connected with the Counties of Oxley, Gregory, and Flinders.

1. With regard to the recommendation that I submitted to you, that weirs should be made in the river Macquarie, by means of which water could be thrown at will through sluice-gates into the Beleringa, Gunningba, Duck, Crooked, and Mara Creeks, I wish to point out that my knowledge of the locality leads me to think that one weir in the Macquarie could be made to serve for both the Beleringa and Gunningba Creeks; another for both the Duck and Crooked Creeks; while a third would be required for the Mara Creek alone.

2. With regard to my suggestion that earth-work dams should be made in lieu of bridges over creeks, which so seldom run or contain water in this dry part of the country, I beg to point out that it would be absurd to expect overshot dams made of earth-work alone, and with the earth-work unprotected, to stand. When I recommended such dams to be made with depressions in the middle, I did so with the intention of merely presenting an idea which might be worked into a practical form by an officer who had received the requisite professional training. I purposely avoided offering detail suggestions in regard to the manner of protecting the embankment, and enabling it to serve the purpose of a roadway. I venture to point out that even if an efficient roadway-dam were to cost as much as a bridge, the fact of its providing water for the traffic ought to cause it to be preferred.

I am, &c.,
WILLIAM FARRER.

APPENDIX V.

WATER Supply by Artesian Wells for the Borough of Tamworth.

THERE can be no doubt but that the question of water supply and conservation is, at the present time, of vital importance to Australia, and of special local interest. An abundant and economic supply of good pure water for inland towns like Tamworth is very desirable, and must largely conduce to the health, comfort, and welfare of the inhabitants. How to secure this great desideratum is a problem that has puzzled the minds of thoughtful and scientific men for many years, and it is only during the last decade that valuable and practical efforts have been made in this country to solve the difficulty. It has been suggested that in all probability an artesian supply could be obtained for Tamworth if proper steps were taken, and that, instead of the borough having to depend for a very limited and partial supply by the present mode of pumping, that the requirements of the whole town could be properly and efficiently provided for, and ample quantity be also available for purposes of irrigation by gravitation, thus saving the enormous and constant expense of pumping, with a possibility of a break-down at any moment. A few weeks since, Mr. Henderson, the Government Superintendent of Drills, after a very short and cursory examination of the country outside of our town boundary, and in the vicinity of Calrossy, reported officially that there was not much probability of water being obtained in that part of the borough except at a very great depth, say one or two thousand feet, and that the town was not badly in want of a better supply than it at present possessed.

As regards this statement, and his conclusions, I beg to differ with him, and believe I can prove he is entirely mistaken, both as regards the depth at which a supply of good water can be obtained and also the necessity for a better supply.

Mr. Henderson, in his first annual report to the Minister for Mines, says there cannot exist a doubt in the minds of any person who has sufficient time to study this very important matter, that water exists underground in the interior in immense quantities, and over large areas. "I believe," he goes on to say, "not only in the existence of large underground supplies held in the horizontal gravel beds of the inland portion of this Colony, but that water exists in the primitive rocks on the tops of which the alluvial formation now lies. I have found at points along the caps of ranges, the slopes of which are within a stone's throw of each other, that it was impossible to sink a shaft in the rocks on the surface beyond 8 or 10 feet deep by means of ordinary labour, because of the water coming in so freely. In numerous instances in the underground workings of mines in Australia, springs can be seen issuing from the stratified rock within a few yards' distance of each other. I am of opinion that there are internal forces other than capillary or gravitation to account for such flow of water from rocks forming the crust of the earth; and, if I am correct in that opinion, there is no reason to suppose that the primitive rocks of the interior, overlaid and covered from the human eye as they are by the alluvial formations, should be less subject to internal forces or supply of water than those rocks of similar character along our main ranges."

This expression of opinion, coming from such an authority, and no doubt formed after long and careful observation, must be very satisfactory to those who believe that an artesian supply can be obtained for Tamworth, and yet, in the face of what Mr. Henderson has deliberately recorded, for some reason or other, certainly not based on the geological formation of the country he examined, he asserts that there are almost insuperable difficulties in the way of our getting an artesian or flowing supply of water. No doubt it depends on the bore, geologically, and to obtain this the water must be stored in the earth, and have communication with an under stream or water-bearing strata, leading from hills situated higher than the ground surface at the bore. The hill source may be a great distance away; still, if the water-bearing strata are overlain with measures of impervious clay, upon these measures being pierced the water will rise to the surface, unless it finds an escape through upper pervious measures. In the upper beds water is frequently met with in moderate quantities but indifferent in quality, and, as it does not rise to the surface, it has to be pumped up. It has been found in bores, otherwise successful, that it does not rise to the surface until the bore is cased; and the assumption is that when the water gets to the level of the the upper drifts it disperses amongst them, but when it is confined to the tube it rises to the surface. There is always a large proportion of underground water which finds a circuitous route for itself by crevices and joints, and, after coursing for, it may be, many miles underground, such water eventually emerges as springs, which contain in solution the various ingredients which the water has chemically extracted from the rocks.

Johnston, in his "Chemistry of Common Life," says:—"It by no means follows in all cases, perhaps not even in the majority, that the purest water is the best for the health of a given family or for the population of a given district. The bright, sparkling, hard waters which gush out in frequent springs from our chalk and other limestone rocks are relished, not merely because they are grateful to the eye, but because there is something exhilarating in the excess of carbonic acid they contain, and give off as they pass through the warm mouth and throat, and, perhaps, because the lime they hold in solution neutralizes acid matters from the stomach, and acts as a grateful medicine to the system. To abandon the use of such a water, and to drink daily in its stead one entirely free from mineral matter and dissolved oxygen and carbonic acid gas, so far from improving, may injure the individual or local health. This authority clearly shows that spring water of the quality and quantity which we can obtain in the mountains at the back of the town is worth having, and would be immensely valuable, not only for ordinary use, but also for purposes of irrigation; and there can be little doubt, judging by results obtained by

by Mr. Patterson, of Calrossy, in sinking a well upon his land on the slope of the hills, that immense underground supplies of water do exist, and that the water is of excellent quality (as any one that chooses may ascertain for themselves), and have not the slighest doubt in my own mind, that if the work was carried out in a proper manner, that is to say a sufficient depth was sunk, and the bore lined with tubing or casing, that a splendid artesian supply would be obtained Mr. Patterson has successfully secured an ample supply for his own purpose, and incontestably demonstrated, not theoretically, but in a practical manner, that Mr. Henderson was wrong in the conclusions he arrived at; and if the townspeople value an ample supply of good water for all parts of the borough, at a small cost, they should at once take immediate action to have a well sunk higher up than where Mr. Patterson has obtained such a fine supply, either by means of a water auger or a diamond drill.

The geological formation in the locality I have indicated is of a very disturbed character, and belongs to the Devonian period, being chiefly indurated slate, and, in some parts, marked by an intrusion of granite. Mr. Patterson, in sinking the well, went through strata of the following nature:—The first 28 feet consisted of clay, gravel, and boulders, and at this depth a small supply of brackish water was obtained; then a rim of cement was placed round this part for the purpose of keeping it back, and a further depth of 32 feet was sunk through clay, and then rock was found of a bluish slaty nature; this changed to a blue rock of a harder character, and, at a depth of 83 feet, a layer of clay, fine gravel, and sand was got 3 inches thick, and immediately afterwards rock was impregnated with quartz 18 inches thick, dipping north-west; the rock again slightly changed, and after sinking 8 feet more, a drill hole was made 2 feet deep, and the water, in a very short time, rose 35 feet, and continues to give a very large supply, as the windmill pump, which is fixed over the well, fails to exhaust or make much appreciable difference in the depth of water in the well.

In all probability this water has its source at a very much higher level than Tamworth, probably in the New England district; and, as Armidale is 2,066 feet higher than Tamworth, if this conjecture should prove correct the weight and quantity of water must be something enormous, and the artesian supply would, consequently, be of a very satisfactory nature. It is unnecessary to dilate upon the great advantages that would be realized by having water supply in the manner I have indicated. The town is rapidly extending to the foot of the mountains, and something must be done immediately to give that portion of it pure and wholesome water at a cheap rate, and with no niggard hand. The soil on and around the mountains is surprisingly rich and fertile, and many industries connected with fruits and wines could be profitably carried on if water could be obtained abundantly and cheaply for irrigating purposes. Not alone could the household requirements be supplied but manufactories also, and a large population would be induced to occupy the lands right up to the mountain tops.

The land in Australia has great powers of absorption, and if, by means of artesian wells and other methods, we can compel Nature to give up freely some of the water that is contained in her great reservoirs, subterraneous caverns and immense underground rivers, the whole face of the country will be materially changed. We can then almost defy the dreadful monster drought, and the hills and valleys would become the abode of prosperous tillers of the soil, and those who follow in their wake; and, instead of this glorious land of sunshine, endowed by Nature with untold wealth and magnificent beauty, having at times to robe herself in sombre hues, a splendid mantle of beautiful verdure would cover her great plains and fertile slopes right up to the mountain tops, and proclaim in unmistakable terms the victory of mind over matter, and another triumph for the scientific and engineering genius of the nineteenth century.

APPENDIX W.

Mr. F. Y. Wolseley to The Secretary.

My dear Sir, Euroka, 17 July, 1885.

The earth excavator which you saw here I patented some time since; but, as I have not had the leisure to attend to the matter, I have had no public trial of it as yet, waiting till I could get one manufactured with improvements, which practical experience of its working proved to me to be necessary. I have now in course of construction a machine which I think will prove very effective. I purpose exhibiting it at the Great National Show of Victoria, to be held next month at Melbourne.

I will describe the general principles of my patent and its mode of working, and generally give you all the information I can.

The Australian Excavator and Earth Scoop is made almost entirely of steel, except such parts where iron is indispensable, thus rendering the machine lighter and more durable than if made exclusively of iron.

Framework of the machine made of angle steel; to the fore-carriage is attached a wrought steel frame, carrying three ploughs or scarifiers, each having double wings working in hinge points trailing behind; thus, at whatever angle the scarifiers may be inclined, the wings always cut behind in a horizontal line. By means of a screw the ploughs can be regulated to cut to any required depth (in practice I have found 3 in. ample). Behind the ploughs, and revolving in direction opposite to their progress, is a large wheel, 9 ft. in height and 2 ft. wide, resembling a water-wheel. The rim to a depth of 9 in. is divided into sections, forming ten buckets for the reception of the ploughed earth; the buckets have their lips protruding beyond the line of circumference of the wheel, thus more effectively scooping in the earth. The depth of cut or scooping capacity of this wheel is also regulated by a screw, and it can be raised from or lowered into the ground rapidly by the man sitting in front. For convenience of travelling he can raise the wheel 1 foot above the ground, as also the ploughs. The bottom of each bucket works on a hinge, and has a trigger attached to it. As the machine is being moved on, each bucket fills with the broken-up earth, and when each bucket so filled arrives at the proper discharging point the trigger strikes against a loose flat tire wheel, which causes the bottom to lift and to thoroughly eject the earth into a shoot attached to the hind part of the main frame. This shoot conveys the earth into a dobbin hooked on to the machine. The capacity of each bucket is nine shovelfuls of earth; thus at each revolution of the wheel there are ninety shovelfuls of earth scooped up and ejected (in practice I would set the figures down at eighty). The scooping-wheel is regulated to travel with intermittent action, thus enabling it more effectually to scoop up the ploughed earth. It travels slower than the machine; thus its revolutions per minute will depend on the speed at which the machine is being drawn along. Roughly, I estimate its general speed, if the machine is worked with oxen, at some seven revolutions per minute, or some 550 shovelfuls of earth per minute. When trying the machine last, with a team of fresh horses, it ploughed, scooped and delivered 840 shovelfuls of earth, making over nine revolutions per minute with each bucketful.

For making drains a side-delivery shoot is attached to the hind part of the machine, and dobbin, of course, detached. As I consider 9 in. ample depth for all drains for the conveyance of water into tanks, width, not depth, is to be considered, for water confined soon cuts and undermines narrow channels, and the less the surface soil is disturbed the better. Thus I regulate the cut for drains at from 8 in. to 9 in. deep, and 4 ft. to 6 ft. wide at the top to 3 ft. to 5 ft. at the bottom. As it is advisable to deliver all the earth to one side of the drain, the shoot can be altered—shifted from side to side at pleasure—thus allowing the machine to travel to and fro over a long or short drain.

When the drain has been cut to the desired depth and width, then, a side-cutter and mould-iron being attached to each side of the front carriage, the slopes to the drain are made. The cutter cuts the earth at any desired angle, and the mould-iron casts it into the drain, to be received and scooped up by the revolving bucket-wheel.

The dobbins will also be made of steel, and will contain about three-quarters of a yard of earth each. They deliver at the bottom, and will thus evenly distribute the earth as it is paid out; whilst in motion each dobbin is attached by ring-chain to a hook fixed at the hind part of the machine. As soon as one dobbin is full, the man sitting in front liberates a handle or lever, and the dobbin is free. The full dobbin is drawn away by horse and an empty one attached, the machine stopping during the few seconds' detention, and then on till that dobbin is full, to be replaced by an empty one. The machine will keep four dobbins in full work, if the distance be not great at which it is decided to deliver the earth; then, of course, the number of dobbins required will depend on circumstances.

To work the machine with oxen or horses requires the attendance of one man to drive the cattle, one man to sit and regulate the working of the machine, and three or four (as many as may be required) boys to drive the horses when emptying the dobbins. In round numbers, I put the working expenses at from 20s. to 30s. per day, and estimate the cost of excavation of earth at less than one penny per yard. This estimate takes not into consideration the first cost of the plant. I cannot rightly state cost of the machine, but can safely assert that with dobbins (three) and all attachments it will not exceed £210. Being made of steel, it will be a little more costly than if made of iron, but it will be more durable and lighter.

There

There are no complicated parts—no part to get out of order that any ordinary man cannot repair. If a rivet should start, small bolts and nuts are supplied to repair the damage in a few minutes. The wings of the ploughs, as also the toe-pieces, are made of steel. These will wear, but can be replaced by fresh ones, carried with machine for the purpose.

I purpose anon making the machine to be worked by steam. The engine and boiler will be borne on the fore-carriage. By this means the cost of excavating will be reduced to a minimum, and in times of drought will be independent, as requiring no grass to keep them going.

There are many details *re* the construction of the machine which are hardly necessary to mention here. The working parts are simple and strong. For making dams or embankments this machine will be found economical, as it will displace manual labour, and when worked by steam can be made to do almost any amount of excavation.

The ploughs in front are made strong enough to cut any of the hardest soil or clay. In the case of exceptionally hard stuff to excavate, the depth can be regulated to the eighth of an inch. The machine I have here is all made of iron, and contains much unnecessary material; yet I have worked it with ten very small oxen, two of them raw steers; but in practice I would use ten oxen or eight horses. The manufacturer, Mr. R. P. Park, engineer, of Melbourne, has sent to England for the necessary steel to be used in the construction of these machines, and as soon as it arrives will proceed with the work in earnest.

Believe me,

Sincerely yours,

F. Y. WOLSELEY.

APPENDIX Y.

Mr. M. Tully to The President.

Dear Sir, 29 May, 1885.

Herewith attached I beg to hand you particulars of strata passed through in boring for water on North Darling Back Run No. 32, situated 22 miles about N. by W. from Bourke, on the western boundary of said run.

I remain, &c.,

MARK TULLY.

STRATA passed through by Tiffin's Borer on Warraweena Station.

Depth.		Description.
3	feet	Surface soil, red loam.
16	,,	Conglomerate rock.
1	,,	Salt water.
5	,,	Stiff blue clay.
18	,,	Conglomerate rock.
5	,,	Conglomerate rock.
40	,,	White chalk.
116	,,	Blue clay and ashes.
7	,,	Black drift.
39	,,	Volcanic scoria.
5	,,	Grey slaty clay.
19	,,	Red clay.
10	,,	Conglomerate quartz and flint.
15	,,	Blue slate reef.
15	,,	Grey slaty rock, hard.
1	,,	Quartz.
7	,,	Gray slate.
4	,,	Blue slaty reef, sandy.
5	,,	Quartz and flint.
40	,,	Blue slaty clay reef.
10	,,	Blue boulder, quartz, and red gravel.
112	,,	Blue slate reef.
493	feet.	

Finished on hard blue boulder too hard for steel-bits to penetrate.

APPENDIX Z.

NOTES on the Geology and Water Supply of the Interior of New South Wales.—By Rev. J. MILNE CURRAN, F.G.S.

Underground Waters.—I take it as proved that the rainfall is largely in excess of water accounted for by soakage, evaporation, or the outflow of rivers; otherwise, or as Mr. Russell puts it, we should expect to find at Bourke a river 200 yards wide and 200 feet deep. The water gets away underground, and the geological history of part, at least, of the interior will explain in what way. By the interior I mean all the country situated west of Dubbo and north of the 33rd parallel. In this country *three* well-marked and distinct geological areas may be distinguished, which for convenience I name as follows:—

I. The Great Tertiary Plains or Merri Merri Country.

II. Siluro-Devonian, or Cobar Giralambone Country.

III. Cretaceous or Warrego Country.

The Plains.—The tertiary plains extend from the Bogan to the northern boundary of the Colony, and are represented to a smaller extent towards the south-west. They are one great alluvial deposit, which show the vast amount of material removed by denuding influences from the western slopes north of the 33rd parallel.

The efficacy of denudation for a work of such magnitude may be doubted; but as we find the plains at every known depth composed of materials similar in character to deposits now in course of formation, it would be rash to say what might not have been accomplished by erosion in a country which has been above the sea since mesozoic times at the very least. Writing of Le Puy, Dr. Geikie says that his first impression was one of utter bewilderment, and upset all previous estimates of the power of rain and rivers. There is almost no amount of waste and erosion that may not be brought about in time by the influence of frost, springs, rain, and rivers. To understand this in our Colony, one has only to travel over some of the hundreds of miles of plains in the interior.

If we imagine the present surface of the interior covered with a deposit of impervious clay, to the depth of 200 feet, the plains would begin about Wellington instead of Dubbo, so far would they encroach on the high lands. The present river would of course flow on to the plains about the same place and cut a bed for itself on the new surface. Now if a well were sunk through this 200 feet of clay a good supply of water would be found in the old river bed, and further, if this well happened to be sunk on that part of the old river which we know as the "Cataract of the Macquarie" the water would rise to the surface we imagine to exist 200 feet above. Diagram II will make this clear. There is a bar of rock on the river at this point which would effectually stay the flow, while the impervious clay above would retain the water in that direction. The supply must be practically inexhaustible, for at the place where the river comes on to the new surface there is the old river bed dipping away, and as capable of absorbing water as if the new deposit never covered it.

Something

Something like what I have been supposing has actually taken place in the past, with this difference, that instead of one old river bed under the plains at one particular level, we have many and on different horizons, from the fact that the formation of the plains extended over great periods of time.

The permanence of drainage-lines is one of the most remarkable facts in the geological history of continents, and Australia is in no way exceptional in this regard. The erosive action of the western rivers and the forming of the plains may have been at work long before miocene times, when the whole southern portion of the continent was upraised some 600 feet. At that time—in the heyday of its youth—the average fall of the Macquarie was much greater than at present, and may be represented by *a—b* (Diagram I). As the plains were formed the river occupied levels as *c*, *d*, *e*, while at the *a* level would be unaltered or eroded if anything. An important point to note is that the newer beds all branch from the old ones, as in the case supposed above, and with like results, namely, that while some water will flow along the new channel, a great deal will still get away by the old bed.

It may be objected that, if the plains were formed in the way I explain, we should have not many old river beds at different levels, but one great bed of river drift that has been slowly raised while the plains were formed. We might, I admit, expect something like this if the rivers deposited alluvium to an equal depth and at the same time over the whole surface of the growing and gradually spreading plains. Then the river would not leave its channel, as when the latter was raised, the banks and surrounding country would be raised to an equal extent. It is almost needless to remark that this is not at all in keeping with our knowledge of the way rivers work in forming plains and depositing alluvium. The great bulk of the transported matter is deposited on or near the banks, so that in time the river margins and eventually the river, will be above the level of the surrounding country. The effect of this, in the end, is to alter the course of the river, only to begin again the same cycle of change. Thus, during the formation of the plains, we have old river beds, (connected with present ones) not only at different levels or on *different horizons*, but also over *separate areas*.

If my explanation be the right one, a glance at Diagram I will show what becomes of the floods that "never come down the river," and will show, too, how all the wells on the plains are down to the river drift, otherwise there is no water. On the plains north of Nyngan I have seen the water, after rain, flow *from* the banks of the creeks towards a depression a few hundred yards away, and disappear at such a rate as would make the creek "run," yet the latter was perfectly dry. A vast amount of the rainfall is absorbed in this way that would otherwise reach the *surface* creeks, and so eventually help to swell the river that would then be flowing by Bourke. At Mullungudgeree and other places the water rises in the wells on the old river drift. After the reference to the "Macquarie Cataract," further explanation of this is unnecessary.

I may observe that I have examined a great number of wells of quite another class from any referred to in this paper. They give good water for a time only, and have been called "surface wells." They are sunk in pans or beds of sand that occupy depressions in the clay. The water is merely surface water absorbed by the sand.

Giralambone Country.—The Cobar Giralambone country consists of inclined silurian slates and schists, with patches of devonian lime and sandstones. The whole area—100 to 150 (?) miles square—is considerably elevated above the plains. Bare and jagged peaks stand out over the general level. Nowhere, as far as I have seen, is the bed-rock at any great distance from the surface. The conditions under which we should expect to find underground waters here and on the plains, evidently differ as widely as the geology of the two districts.

Warrego Country.—Of the Cretaceous or Warrego country I cannot at present speak from experience; but it is clear to every geologist, from what is known of cretaceous rocks, that, as regards underground waters, we are justified in separating the areas where these rocks occur from both the Great Tertiary Plains and the Cobar Giralambone country.

N.B.—By barometer I make last peg of railway survey 20 feet above my BM here: all other levels can be found in my evidence before Commission.—J. H. MEDHURST, Jr., 19/11/85.

APPENDIX DD 1.

License.

THE Road Board of the Courtenay Road District hereby grants unto the owner or occupier for the time being of part of rural section, number hereinafter termed the licensee, full and free liberty and license at all times hereafter until such liberty and license shall be revoked, under the provision in that behalf hereinafter contained, to take and convey water by means of pipes, culverts, aqueducts, inlets, or other similar works, to be hereafter laid down for such purpose, from the public water-race, or any branch thereof, across, under, or upon the public road adjoining the said rural section, for the use of the said lands and the owner or occupier thereof, subject to the following stipulations and provisions to be performed and observed on the part of the licensee:—

1. That the connection for the purpose of conveying the water from the public water-race to the lands of the licensee, and all works and materials necessary for effecting the same, be made, done, and provided by the licensee at his expense, but subject in all respects to the approval of the Road Board or its Surveyor.

2. That, subject to the like approval, the licensee will, at his own expense, at all times, and from time to time, cleanse, amend, repair, and relay, whenever the Road Board shall require him so to do, all or any of the said pipes, culverts, aqueducts, inlets, or other works, and keep and maintain the same so cleansed, amended, and repaired, so that the same shall not become a nuisance to the public, or otherwise interfere with the public traffic on the roads under the care and control of the Road Board.

3. That the licensee will at all times hereafter indemnify and keep indemnified the Road Board, its successors and assigns, servants, agents, and workmen, of, from, and against all claims, demands, costs, charges, and expenses which may any time hereafter be made, preferred, or established against the said Board, or which the said Board may pay, sustain, or be liable for, or by reason or on account of the authorities, rights, and powers granted by this license, or in respect of the said works, or the interference with any public road by the said works, or in respect of any act, matter, or thing done, or damage occurring from time to time in relation to the same, or otherwise howsoever.

4. That the Road Board, its servants, agents, and workmen, may at all reasonable times enter upon the lands of the licensee adjoining the said works for the purpose of inspecting and viewing the said works; and no trespass shall be thereby committed by the said Board or its servants, agents, or workmen, nor any claim for compensation be made by the licensee in respect of such entry.

5. It is hereby agreed and declared that the Road Board, its successors and assigns, shall have full power and authority at any time hereafter, upon giving to the licensee seven days' notice in writing, or leaving the same upon the land of the licensee, to revoke and make void the liberties, licenses, and powers hereby granted, in which case the materials forming the said connection may be removed, and the surface of the public road made good by the Road Board at the expense of the licensee.

Granted this day of 188 , and sealed with the common seal of the Courtenay Road Board.

Chairman.

Countersigned,—

Clerk of the Board.

I hereby accept this license, and agree to observe and be bound by all the foregoing conditions thereof.

Witness to signature,—

APPENDIX DD 2.

An Act to authorize the Transfer of a certain Water-race, known as the Malvern (N.Z.) Water-race, to the Corporation of the County of Selwyn. [29th October, 1878.]

Preamble.

WHEREAS a certain water-race, known as the Malvern Water-race, has been constructed in the Provincial District of Canterbury, for the purpose of supplying water to landowners, farmers, and others, and such water-race has been hitherto maintained by the Government, and it is expedient for the better management thereof that such water-race should be handed over to the Corporation of the County of Selwyn, wherein the same is situate:

Be it therefore enacted by the General Assembly of New Zealand in Parliament assembled, and by the authority of the same, as follows:—

Short title.

1. The short title of this Act shall be "The Malvern Water-race Transfer Act, 1878."

Definition of "water-race."

2. The word "water-race" includes the land occupied by the water-race, and all streams, waters, and rights appertaining thereto, and all reservoirs, dams, tanks, and pipes, and all machinery and appliances of every kind connected therewith acquired or constructed by the Council under the authority of this Act for conveying water to or through the county. "Council" means the County Council of the County of Selwyn.

Malvern Water-race may, by Order in Council, be vested in Corporation of County of Selwyn.

3. The Governor, by Order in Council, may vest the Malvern Water-race aforesaid in the Corporation of the County of Selwyn, upon such terms and conditions as the Governor in Council thinks fit. When so vested, such water-race shall, subject to the terms and conditions mentioned in such Order in Council, be deemed to be the property of such Corporation for the purpose of all actions, suits, and proceedings in respect thereof or in relation thereto, so long as such water-race remains so vested; and the Council shall have and exercise over such water-race the powers and authorities conferred by any such Order in Council and by this Act.

Powers of Council.

4. The Council may complete, extend, and enlarge the said water-race, and may keep the same in good repair, and may from time to time do all things necessary thereto; and therein especially may do the following things:—

(1.) May make surveys upon any lands within the county;

(2.) May purchase or take, under the provisions of "The Public Works Act, 1876," land or any estate or interest therein;

(3.) May break up or dig into the surface of any public place or road within the county, and temporarily stop the traffic on any such public place or road so far as is necessary for the construction or repair of any part of the water-race, and alter any drain or sewer on or under any public place or road so far as is necessary for such construction or repair, and alter the course or level of such public place or road for such purpose;

(4.) May, with the consent of the Governor, make such water-race over or under or through any public reserve;

(5.) May alter the course or level of any stream or river, or of any ditch or drain, and take, impound, or divert the water from or turn water into any stream, river, ditch or drain, and make dams, sluices, reservoirs, or other water-race in any such stream or river.

(6.) May enter upon any lands and take therefrom any materials required for the construction or repair of the water-race;

(7.) May construct all works, buildings, and machinery, of every description and material, and generally may do all things necessary for the construction, repair, maintenance, and use of the water-race.

Any land or water so taken for waterworks shall be taken under the provisions of "The Public Works Act, 1876," and Acts amending the same.

Persons suffering damage or loss to be compensated.

5. Every person having any estate or interest in any land, water, or buildings taken under the authority of this Act, or suffering any damage by the exercise of any of the powers hereby given, shall be entitled to full compensation for the same, which may be claimed and shall be determined in the manner provided by the Third Part of "The Public Works Act, 1876;" and in any such proceeding the Council shall be deemed to be the respondent within the meaning of the said "Public Works Act, 1876."

Private land not to be entered without consent of owner.

6. Nothing herein shall authorize the entering upon any private land without the consent of the owner, except for the purpose of making surveys, or until such land is taken by the Council as above provided; but if any part of the water-race is at any time, with such consent, put on or under any private land, the Council may thereafter enter thereon to repair such part when required.

7.

By-laws as to rates and charges.

7. The Council may from time to time make, alter, and repeal by-laws prescribing the terms and conditions upon which the water-race may be used, and prescribing the rates and charges to be paid for water supplied, and may fix a penalty of not exceeding ten pounds for the breach of such by-laws.

All such rates and charges may be recovered by and in the name of any person duly authorized by the Council in that behalf as an ordinary debt in any Court of competent jurisdiction.

Penalty for taking water from water-race without consent of Council.

8. It shall not be lawful, without the consent of the Council or of some person appointed by the Council, for any person to take or divert any water from the water-race; and any person who, without such consent as aforesaid, does or causes to be done any act whereby the water in any such water-race is drawn off or diminished in quantity, shall be liable to a penalty of not more than five pounds for every day during which the supply of such water is so drawn off or diminished. The Council may recover from such person the amount of any damage sustained by reason of the taking or diverting of such water.

Penalty for damage done to water-race.

9. If any person wilfully or maliciously destroys or does any damage to the water-race, or if any person permits his cattle to trespass on the water-race and thereby any damage is done to the water-race, such person shall be liable to a penalty of not more than one hundred pounds, and in addition to pay the whole cost of restoring such damage.

Person taking water from water-race without paying charges to be fined.

10. If any person unlawfully obtains water from the water-race without payment of the lawful charges, or in other manner than as provided by the by-laws made by the Council, he shall be liable to a penalty of not more than fifty pounds.

Penalties to be recovered in a summary manner.

11. All penalties under this Act, or any by-laws made thereunder, may be recovered in a summary manner before two or more Justices of the Peace, in the manner provided by the "The Justices of the Peace Act, 1866."

APPENDIX DD 3.

MALVERN (N.Z.) WATER-RACE TRANSFER ACT 1878 AMENDMENT.

Title

A Bill intituled an Act to amend "The Malvern Water-race Transfer Act, 1878," and to confer upon the Council of the County of Selwyn special Rating and Borrowing Powers in respect of the said Water-race.

Preamble.

WHEREAS it is expedient to amend "The Malvern Water-race Transfer Act, 1878," and to confer upon the Council of the County of Selwyn, in respect of the said Water-race, special powers of rating and borrowing:

Be it therefore enacted by the General Assembly of New Zealand in Parliament assembled, and by the authority of the same as follows:—

Short title. Interpretation.

1. The short title of this Act is "The Malvern Water-race Transfer Act 1878 Amendment Act, 1880."

2. In this Act—

"The said Act" means "The Malvern Water-race Transfer Act, 1878":

"District" means and includes the lands described in the Schedule:

"Council" means the Council of the County of Selwyn.

"Counties Act, 1876," and other Acts incorporated.

3. The provisions of "The Counties Act, 1876," "The Rating Act, 1876," and "The Rating Act 1876 Amendment Act 1879," so far as they are consistent with and applicable to the objects and provisions of this Act, are hereby incorporated with and shall be read as part of this Act.

Special rate may be levied as security for loan.

4. The Council, by special order, may make and levy a special rate not exceeding 1s. in the £, on all ratable property within the district for the purpose of securing the repayment of the moneys to be borrowed, as hereinafter mentioned, with interest.

County of Selwyn may borrow £35,000 for constructing Malvern Water-race.

5. The Council, from time to time, as occasion may require, may borrow and take up at interest any sum or sums of money, not exceeding in the whole the sum of *thirty-five thousand* pounds, on the security of the said rate, for the purpose of constructing, completing, extending, enlarging, repairing, and maintaining the said water-race and the works connected therewith, and of otherwise carrying into effect the provisions of the said Act, and for paying all expenses incidental to the raising and borrowing of such moneys.

Notice of special loan to be published.

6. The Council shall publish in the district once in each week, for four successive weeks, a notice setting forth,—

(1.) The particular work proposed to be undertaken.

(2.) The sum proposed to be borrowed for such purpose.

(3.) Any special rate, or tolls, or the rents and profits of any property which it is proposed to pledge as security for such loan, not being moneys received by way of grant from the General Government, or moneys heretofore pledged as security for any loan, or appropriated to any special purpose.

Chairman to call meeting of ratepayers to consider proposal to borrow.

7. The Chairman shall call a meeting of the ratepayers of the district, to be held within the district upon a day not *less* than ten, *nor more than twenty*, days after the last publication of such notice, to consider the said proposal; and every such notice shall be published in a newspaper circulating in the district, and shall specify the time and place in the district at which the meeting is to be held.

Chairman to appoint person to preside.

8. The Chairman shall appoint one of the members of the Council elected for any riding included, or partly included, in the district, to preside at each meeting, if such member shall be willing to act; and if no such member is willing to act, or becomes incapacitated from acting for any cause, then such person as the Chairman thinks fit.

The member or person so appointed shall be called the "Presiding Officer," and he shall be Chairman of the meeting to be held in the district, and shall act as such at the taking of any poll, as hereafter provided.

After due consideration and discussion of the proposal, the presiding officer may give notice that a poll will be taken.

How poll to be taken.

9. The poll shall be taken as follows:—

(1.) The Chairman shall publish a notice setting forth the day, not less than one *week* nor more than three weeks, from the day of the said meeting on which the poll will be taken.

(2.) The Chairman shall give notice in writing to the presiding officer, requiring him to take the poll upon the day appointed.

(3.) The presiding officer shall, upon the day so appointed, proceed to take the poll in the manner provided by "The Regulation of Local Elections Act, 1876," for taking a poll at any election, and shall provide voting papers and all things necessary for taking the poll.

Second Schedule

(4.) The voting papers shall be printed in the form in the Second Schedule, setting forth the notice mentioned in the sixth section with the declaration in such form set forth, and the words "I vote for the above proposal," or, "I vote against the above proposal," legibly printed at the foot of each voting paper.

(5.) The voter shall erase one or other of the said lines, and his vote shall be deemed to be given according to the one of the said lines which he leaves unerased.

(6.) All the provisions of "The Regulation of Local Elections Act, 1876," as regards taking a poll, shall, so far as they are applicable, and except as by this section otherwise provided, apply to the taking a poll on the proposal to raise a special loan.

When resolution deemed to be carried.

10. If the number of votes given for the proposal within the district taken together exceeds the number given against it by one-fifth or more than one-fifth of the latter, the resolution in favour of the proposal shall be deemed to be carried, and the Council may proceed with the proposal accordingly; but if there is not such a majority in favour of the proposal, the resolution shall be deemed to be rejected, and the Council shall not so proceed.

Chairman to declare numbers polled.

11. As soon as conveniently may be after the result of the poll has been ascertained, the Chairman shall give public notice of the number of votes recorded for and against the proposal as above provided, and shall declare the resolution to be carried or rejected, as the case may be.

And send result of polling Colonial Secretary.

12. When any such resolution is carried, the Chairman shall send a notice thereof to the Colonial Secretary, who shall publish the same in the Gazette, and such notice so gazetted shall be evidence that the raising of the loan to which it refers has been duly authorized under the provisions of this Act.

13. The re-payment of such moneys, with interest, shall be secured to the lender or lenders thereof, upon or by debentures to be issued under the authority of this Act. Debentures.

14. The net proceeds of the said rate shall be paid and applied by the Council in manner following, that is to say— Application of rates.

Firstly—In payment of the interest on the sum or sums of money to be borrowed.

Secondly—In providing a sinking fund *of not less than one pound per centum per annum upon such sum or sums as shall from time to time be raised under the authority of this Act* for the repayment of the principal of such moneys.

THE FIRST SCHEDULE.

ALL that area of land situate in the provincial district of Canterbury, and estimated to contain by admeasurement 89,525 acres, bounded as follows:—Commencing at the south corner of R.S. 4,708, thence along the eastern boundary of R.S. 4,708 to the lower Waimakariri Road; thence along the southern boundary line of the road to the north-east corner of R.S. 15,744; thence along the eastern boundary of the said section to the north corner of R.S. 17,637; thence along the north boundary of R.S. 17,637, and south boundary of R.S. 14,865 to the Racecourse Hill and Bleakhouse Road; thence along the southern boundary of the road to the north-west corner of R.S. 14,866; thence along the western boundary of R.S. 14,866 to the northern boundary of R.S. 18,489; thence along the northern boundaries of R.S. 18,489, reserve 1,329, R.S. 10,233, 14,691, 14,970, 16,237, 12,285, 12,289, 14,854, 14,517, 8,995, 9,135, 10,181, 3,743, and the eastern boundary of R.S. 3,473 to the Homebush Road; thence along the north boundary of the Homebush Road to the Kirwee Road; thence along the east boundary of the Kirwee Road to the north-west corner of R.S. 8,894; thence along the north boundaries of R.S. 8,894, 8,866, 8,989, 6,721, to the public road; thence along the northern boundary line of the public road to the south-west corner of R.S. 5,782; thence along the eastern boundary of the Sandy Knolls Road to the south-west corner of R.S. 6,467; thence along the north boundary of the road to the south-west corner of R.S. 20,658; thence along the erst boundary of the road to the south-west corner of reserve 1,455; thence along the south-western boundary of reserve 1,455 and R.S. 22,647; thence along the east side of the public road to the north corner of R.S. 7,743; thence along the south-west boundary of reserve 720 and R.S. 8,163 and 7,795; thence along the south-eastern boundary of 7,795 and 7,569, and the north-eastern boundary of R.S. 4,962 to the north side of the Railway Reserve; thence along the northern boundary of the Railway Reserve to the east corner of R.S. 4,256; thence along the south boundary of the public road up the bank of the Selwyn River to the south-east corner of R.S. 15,024, and thence along the south boundary of the road to the north corner of R.S. 16,011; thence along the east boundary of the road to the bank of the river Hawkins; thence along the left bank of the river Hawkins to the west corner of R.S. 4,460; thence along the north boundary of R.S. 4,460 and west and north boundaries of 15,106 to the Malvern Railway Reserve; thence along the west boundary of the Railway Reserve to a point opposite to the commencing point, and thence across the reserve to the commencing point.

SECOND SCHEDULE.

Form of Voting Paper for Special Loan.

Proposal to raise a special Loan, upon which a poll will be taken on the day of , 18 .

(*Insert the notice required by the 9th section of the Act.*)

1. I vote FOR the above proposal.
2. I vote AGAINST the above proposal.

APPENDIX FF 2.

PARTICULARS of Improvements for the Conservation of Water on Toganmain.

Portion.	Description.	Value.	Portion.	Description.	Value.
	Parish of Mulburruga.	£ s. d.		Parish of Mucleay.	£ s. d.
41	Tank on portion 41, parish Mulburruga, and portion 55, parish Eilginbah.	400 0 0	21	Tank	460 0 0
55			17	Well, tank, and troughing	480 0 0
			48	Tank	500 0 0
	Parish of Toganmain.			Parish of Gundadaline.	
63	Excavation	520 0 0	100	Well, tank, and troughing	460 0 0
49	Do	180 0 0	19	Tank	180 0 0
			24	Do	800 0 0
	Parish of Singorambah.		31	Do	420 0 0
78	Tank	250 0 0	28	Do	350 0 0
35 & 36	Do	340 0 0	1	Tank and dam	520 0 0

[15*s*.]

1886.

NEW SOUTH WALES.

ROYAL COMMISSION—CONSERVATION OF WATER.

SECOND REPORT OF THE COMMISSIONERS.

To His Excellency the Right Honorable CHARLES ROBERT, BARON CARRINGTON, Knight Grand Cross of the Most Distinguished Order of Saint Michael and Saint George, Governor and Commander-in-Chief of the Colony of New South Wales and its Dependencies, &c., &c., &c.

MAY IT PLEASE YOUR EXCELLENCY,—

In our First Report we drew your attention to the natural facilities which exist for the utilization of the flood-waters of the Murray over a large portion of the fertile soil which lies between that river and the Murrumbidgee, and to the advantages which might be expected to result therefrom. We also informed your Excellency that we had it in contemplation to confer with the Royal Commission appointed by the Government of Victoria to report upon the question of Water Supply, with a view to ascertain a basis upon which the Colonies of New South Wales and Victoria might agree to the diversion and utilization of the flood-waters of the Murray in their respective territories. In the fulfilment of this intention we met the Members of the Royal Commission of Victoria in conference at Melbourne, on the 22nd and 23rd of January, and in Sydney on the 5th and 6th of May.

The first deliberations of the Conference were embarrassed by the want of accurate information on several points; as, for example, the quantity of water required to maintain navigation; the quantity available for distribution for purposes of stock, agriculture, or mining; the quantity contributed by the drainage area of New South Wales and that of Victoria; the extent to which water is being and will be diverted from the Victorian tributaries of the Murray; the extent to which flood-waters can be impounded by works of storage, and the extent to which they can be utilized by one Colony or the other. The attention which the Public Departments of this Colony has hitherto been called upon to give to our rivers has had reference chiefly to the removal of obstructions to navigation; and any information which can be obtained in regard to the discharges of the rivers is fragmentary. Under these circumstances the members of both Commissions were fully agreed as to the propriety of making a thorough examination of the Murray and its tributaries, as by that means only can be obtained the data upon which action for the common benefit can be taken. It was, therefore, at an early stage of their deliberations, unanimously resolved—

> "That the Governments of New South Wales and Victoria are invited to take joint and immediate action for a thorough examination of the Murray River and its tributaries, and the accurate gauging of the discharge at various points."

We

We forwarded a copy of this resolution to the Honorable the Colonial Secretary on the 24th of February, with an intimation of our willingness to co-operate with the Commissioners for Victoria in making the inquiry. The Government of Victoria have expressed their readiness to bear half the cost of the examination.

We assume that the sites for weirs and other works which may have to be constructed to conserve or to divert water, will be determined upon after a careful examination by competent engineers of all the circumstances which should govern their selection, in view of the requirements of the Colonies to be benefited, and the cost at which the benefits could be secured. Works of this character would, in the first instance, require the sanction of the Parliaments of New South Wales and Victoria, and we assume that, the necessary appropriations having been made, the construction of them would be devolved upon the joint Trust which we recommend shall be called into existence, and in which the control of the Murray shall be vested. It will be seen, from their sixth recommendation of the final resolutions, that the Commissions are of opinion that the amount of benefit which each Colony could derive from any particular work should form the basis upon which should be ascertained the proportion of cost which the Parliament of each Colony would be invited to provide.

The 5th section of 18 and 19 Victoria, chapter 54, enacts "that the whole watercourse of the River Murray, from its source to the eastern boundary of the Colony of South Australia, is and shall be within the territory of New South Wales." The section also empowers the Legislatures of Victoria and New South Wales to make regulations for the levying of Customs duties on goods imported by way of the Murray, and for the navigation of the river by vessels of the two Colonies respectively. New South Wales has, therefore, the legal right to divert the flood-waters of the Murray to any extent which may be deemed expedient, so long as the navigation of the stream is not impaired by such diversion. Thus, for example, we believe that the Government of New South Wales would be acting strictly within their statutory rights if they were to cut channels into the northern bank of the Murray, to allow the flood-waters of the river to be utilized in the country to the north of the river; but we do not acknowledge that Victoria has the same right, although she has assumed to exercise it by deepening the Gunbower Creek, which is a Victorian effluent of the Murray.

We recognize, however, that the question cannot be dealt with in a manner which will be satisfactory to both Colonies if reference is had solely to its legal aspect. The largest and most advantageous use of the water must depend upon the construction of works of great magnitude, designed to conserve water on an extensive scale, so as to maintain a constant and, as far as practicable, an equal volume of water in the channel of the river, and also, upon the construction of works to increase the height of the river at certain points, to divert by means of gravitation, through artificial channels, so much of the water as may be available for irrigation, mining, pastoral, or other uses in the two Colonies. No work of this character could be constructed without the full consent of both Colonies within whose territory some portion of it must be placed, for physical and political considerations would frustrate the completion of any such works projected by New South Wales if they were objected to by Victoria. It is furthermore certain that the cost of the works necessary for the improvement of the river would be very great; and every consideration of policy and right feeling leads to the conclusion that the question of improving the Murray and utilizing its flood-waters should be dealt with on the durable and satisfactory basis of mutual help for mutual benefit.

We are fully aware that no action which it might be in our power to take could abrogate the legal rights of ownership in the Murray, which, as we have seen, is by the Constitution Act vested in the Legislature of New South Wales. We nevertheless did not desire to insist upon such an extreme view of our statutory position as should preclude the consideration and recommendation of any scheme which might seem to be equitable and advantageous to the two Colonies. It appears to us that, for reasons, some of which are indicated in the last preceding paragraph, and others not less cogent which will readily suggest themselves, that for New South Wales to insist upon her statutory right to the exclusive ownership of the Murray—qualified as that right is by co-ordinate powers in regard to navigation and the collection of Customs duties by the Government of Victoria, and by the riparian rights of the inhabitants of Victoria who are settled upon the southern bank of

the

the stream—is to take up a position which may embitter the future political relations of the two Colonies, and which must injuriously retard the development of their material interests. Finding that the Commissioners for Victoria are prepared to recommend that the Mitta Mitta and the Kiewa shall be dealt with as an integral portion of the Upper Murray, we, on our part, are prepared to recommend the waiver of the advantage of our superior legal position, in order to secure, as far as may be practicable, the utilization of the waters of the river which now flow wastefully into the sea. The annual money value of the water now lost would be represented by millions of pounds sterling, and we anticipate that the examination of the river which we have recommended will establish the fact that it is quite within the power of engineering skill to devise means for the conservation and distribution of the flood-waters of the Murray to an extent which, on self-supporting economical conditions, will endow with perpetual fertility large districts in both Colonies—districts which, however rich may be the soil, must, without irrigation, remain useless for the purposes of agriculture.

As the legal position of the question contains no sufficient basis on which to form an agreement which would be accepted by the two Colonies as satisfactory, attention was next directed to the amount of water contributed by New South Wales and Victoria to the Murray, with a view, after providing for compensation water, of authorizing each Colony to divert from the river the proportion of the surplus to which it would be entitled on the basis of contribution. The deliberations of the Commissioners, however, in this direction disclosed numerous important and, as it it appeared to them, insuperable difficulties. Thus, for example, it would be well-nigh impossible to reconcile the conflicting claims which have been, and would be, put forward on behalf of each Colony as to the quantity of water contributed from its respective drainage areas. The extent only of the drainage areas form no criterion as to the quantity of water which flows from them; for it is obvious that while a rocky and precipitous country will discharge a very high percentage of the rainfall into its streams, a district whose soil is flat and porous will absorb the whole of a moderate rainfall. The question, as a matter of calculation, is rendered still more difficult by the inequality of the rainfall itself, and that within comparatively limited areas. The rain observations on the Upper Murray are confined, in New South Wales, to two stations; and while the record at Kiandra gives the fall at 61 inches, that at Albury shows only 26 inches per annum. The number of stations at which rain records are kept will have to be greatly multiplied, and the records continued for many years (some meteorologists would say sixty at least), before it would be possible to form a reasonably approximate estimate of the mean average rainfall. It has not unfrequently happened that, while a large part of one Colony has been deluged with floods, a considerable area of the other has been parched up with drought, and it would not be practicable to gauge the quantity of water contributed by floods other than that flowing down the channels of tributary streams. If it were possible to overcome these difficulties, and to deal with the waters of the Murray on the principle of a debtor and creditor account, we anticipate that, owing to differences in the configuration of the different districts bordering on the stream, and to the variety of local interests, such an arrangement would break down under the political contention which it would be sure to engender.

The principle upon which the tributaries of the Murray should be dealt with has also necessarily engaged our attention. In our first report we have recorded (page 66 and sequel), we hope with sufficient clearness and fulness, our reasons for thinking that the presumptions of English law in regard to riparian rights are not applicable to the conditions of New South Wales, where, in too many cases, what are called rivers are actually the dry channels of watercourses, which need to be converted into canals; and this opinion has led us to the conclusion that each Colony must be allowed to deal with the tributaries of the Murray in such manner as will best conduce to its own development, with the sole reservation that a certain proportion of the water contained in those streams must be allowed to flow into the Murray. For the sake of convenience, we have called this proportion of the rivers' discharges "compensation water;" for by this means the residents on the banks of the Murray or of any of its tributaries will be "compensated," or, more correctly speaking, protected from injury, which would be inflicted upon them if works for storage higher up the stream were to impound the whole supply. This principle of augmenting the supply and regulating the flow of water

in

in any particular stream seems to us to preserve all that is valuable in the doctrine of riparian rights, and, as the Colonies advance in population and wealth, and are thereby enabled to carry out works for this description of river improvements, it will stimulate production to an extent now hardly dreamed of, and may be the means in years to come of completely altering the face of the country. A just application of the principle will safeguard the rights of South Australia, which we recognize to be as valid as our own; but the logical outcome of legal presumptions in regard to the riparian rights, if Queensland, New South Wales, Victoria, and South Australia, were one community, would enable the last named Colony to insist on the uninterrupted flow of an immense proportion of the whole rainfall of the Continent, simply because the waters of the Murray run through her territory to the sea. As we could not think that the Legislature will for ever permit the rainfall of that wide extent of our Colony which lies to the west of the Main Dividing Range, which is collected in the Murrumbidgee, the Lachlan, and the Darling, with its important tributaries the Macquarie, the Castlereagh, the Namoi, and the Macintyre, to be unutilised, in so far as their flood-waters are concerned; neither could we feel justified in attempting to interpose any barrier to action on the part of Victoria for the utilization of the flood-waters of her tributaries to the Murray.

It will be seen from the third resolution of the Conference that we have agreed to recommend that the waters of the river Murray, including the whole of its tributaries above Howlong, shall be deemed to be the common property of the two Colonies; and we trust that it will appear to your Excellency, and to the Parliaments of the Colonies interested, that the recommendation is based upon equity and the dictates of sound policy. All other solutions of the matter which have engaged our thoughts have been so full of complexity, and fraught with so many technical difficulties, that we could entertain little hope of their being made readily intelligible to popular comprehension, or of their commending themselves to the conscience and judgment of the communities which dwell on either side of the Murray, with whom, through their representatives in Parliament, the ultimate settlement of the matter must rest.

We hope, also, that the proposal to create, under Legislative sanction, a joint Trust, in which should be vested the control of the Murray, is one which will be regarded as being of a simple and practicable character. The functions of that body would be to make recommendations as to the sites and character of storage works, weirs, and off-takes, to supervise the construction of such works, and to authorize the diversion of water from the river, subject to statutory limitations designed to secure and guard the rights of each Colony. In times of high flood the quantity of water is greater than can be dealt with by any improvement of the river itself, but an examination of the country may show that it is possible to divert water in such cases to natural depressions or creeks at a distance; and, to meet such cases as these, we recommend (Res. 5) that the Trust shall be empowered to fix levels at which it shall be at the option of either Colony to appropriate flood-waters as it may deem expedient, without the same being debited against them. By this means it is hoped that the injury resulting from high floods may be mitigated, while, at the same time, districts adjacent to the Murray will be benefited.

The resolutions of the Conference appear to us to be sufficiently perspicuous not to require further explanation, and we therefore submit them with our recommendation that they may form the basis of a treaty between New South Wales and Victoria. They are as follows:—

1. That a joint Trust shall be constituted, equally representative of the Colonies of New South Wales and Victoria, in which shall be vested the control of the whole of the Murray River and its tributaries from its source to Howlong, to be known as the Upper Murray; and of the whole of the Murray River from Howlong to the eastern boundary of the Colony of South Australia, to be known as the Lower Murray; and such Trust shall have power to regulate all diversions of water from the river and tributaries within its jurisdiction.
2. That the waters of the tributaries of the Lower Murray, except such proportions thereof as shall, under the direction of the Trust, be required as compensation water for the main river, may be diverted and used by the respective Colonies through which they flow.

3. The whole of the waters of the Upper Murray and its tributaries, and the whole of the waters of the Lower Murray, shall be deemed to be the common property of the Colonies of New South Wales and Victoria. And, subject to the reservation of such compensation water as the Trust may from time to time determine, each of the said Colonies shall have the right to take and divert one-half of such water at such point or points as may, with the sanction of the Trust, be fixed on as most suitable for the requirements of such Colony. Provided always that the totals of the quantities so diverted by the two Colonies, when the whole surplus (after providing compensation water as above) is utilized, shall be equal.

3. That all natural diversions of water from the Murray shall be gauged under the direction of the Trust, and the portion of such diversions not returned to the channel of the main river shall be debited to the Colony into which such water is diverted, in the same manner as if such diversion had been made under the last preceding section.

5. That the Trust may fix and determine levels to be known as the high-flood levels of the Murray, and may make such regulations for the disposal of water flowing above such levels as to it shall seem expedient.

6. That works for the storage and regulation of the waters of the Murray may, under the supervision of the Trust, be constructed at the joint cost of the Colonies of New South Wales and Victoria, such cost to be borne by each Colony in proportion to the benefits derived by it from such works.

7. That, so far as possible, the two Colonies shall take united action in respect of all works intended to provide for the utilization of the Murray waters.

8. That the Trust shall consist of not more than six members, three of whom may be appointed by the Government of New South Wales and three by the Government of Victoria, such members to hold office for terms of not more than five years. The expenses of the Trust and its officers to be defrayed by the two Colonies in equal proportions.

9. That a Bill, embodying the above resolutions, shall be prepared under the supervision of the Water Supply Commissions, for submission to the Parliaments of New South Wales and Victoria. The Government of each Colony, having approved of the measure, shall be requested to secure for it the earliest possible consideration by its Legislature.

10. That the Governments of the respective Colonies of New South Wales and Victoria shall be requested to hold themselves bound, *ad interim*, by the provisions of the above resolutions until they shall be dealt with by the Legislatures of both Colonies.

Capital has been invested in steamers, barges, wharves, and warehouses, and the facilities for communication and the transport of commodities afforded by the Murray to the dwellers upon its banks and in districts more remote have been considerable, but the necessity of navigation is being gradually superseded, and it is by no means improbable that, before the time arrives for joint action on the part of Victoria and New South Wales in the construction of weirs, anything like the through navigation of the Murray will be abandoned as unprofitable. We have not been able to ascertain the extent and value of the river-borne traffic, inasmuch as our Customs returns from the stations on the Murray do not specify the value of commodities carried across the river at the different points as distinct from that of those brought by the steamers. The river may be said to be navigable as far as Albury; but as a matter of fact there has been no steamboat traffic between Tocumwal and Albury during the last five years. The requirements of the district, so far as New South Wales is concerned, are met by the railway to Albury, and that which is projected to Corowa. Echuca, or Moama, may therefore be said to be the head of navigation; but it appears probable that when the railway now approaching Swan Hill is opened for traffic, that place will afford the most direct means of communication with Melbourne, and will therefore arrest the river-borne trade which now passes it for the railway at Echuca. The continuation of the line from Hay to Wentworth may be expected to diminish the amount of the river traffic;

traffic; and the importance of navigation, so far as the Murray is concerned, may also be still further lessened by the further development of the railway systems of South Australia and Victoria. The following statement, obligingly supplied by the Collector of Customs, confirms us in the opinion that navigation is steadily declining in importance.

Number and Tonnage of Vessels cleared at Moama, Swan Hill, and Euston :—

Year.	No.	Tonnage.
1881	182	43,115 tons.
1882	151	37,493 ,,
1883	146	32,482 ,,
1884	122	22,368 ,,
1885	118	21,027 ,,

No steamboat traffic to Albury, Howlong, Corowa, Mulwala, and Tocumwal.

The mercantile interests of Victoria are still largely concerned in the navigation of the Murray; but we think there is good reason to doubt whether even Victoria would be willing to incur the enormous expense of constructing locks as well as weirs for the maintenance of navigation as it is now carried on. So far as the interest and convenience of the inhabitants living on the banks of the Murray are concerned, the construction of weirs to raise the height of the river would rather increase than diminish their facilities of communication, and the navigation of the river in sections is compatible with the fullest utilization of its waters for the purposes of agriculture. But in view of the state of transition in which the border traffic is at present, we are not willing to make any recommendation in the direction of expenditure to increase facilities for navigation.

On the occasion of our visit to Victoria, we had, by the courtesy of the Commissioner for Water Supply in that Colony, an opportunity of inspecting several of the principal works in connection with schemes which have been devised for supplying water to the arid districts of Victoria, and we now submit the information we were able to obtain :—

In order to afford a clear conception of the present state of the water supply question in the country districts of Victoria, it is necessary to describe briefly the measures under which the subject has reached its present stage.

Early in 1880 Messrs. Gordon and Black were instructed—1st, "To inquire and report as to the feasibility of providing, at a reasonable expense, a supply of water to the northern plains, for domestic purposes and the use of stock"; and 2nd, "as to irrigation." In the preparation of projects dealing with the former branch of the subject, Messrs. Gordon and Black aimed at bringing a supply of water for domestic use and for stock within a maximum distance of about 3 miles throughout the various districts dealt with. It was proposed to attain this object by providing a system of watercourses and tanks at intervals of 6 miles. The reports and plans showing how this could be accomplished have in the main been adhered to in the works already constructed under the various Waterworks Trusts, and there seems little doubt that they will supply the groundwork of nearly all the works still to be carried out. The projects included the utilization of a large proportion of the waters of the Wimmera, the Avon, the Avoca, the Loddon, the Campaspe, and the Broken Rivers, and the whole of the ordinary supply of the Goulburn was proposed to be diverted, partly for stock and domestic use, but chiefly for irrigation. In short, all the Victorian tributaries of the Murray which flow through the northern plains, with the exception of the Ovens, were dealt with in a comprehensive manner. The general principle recommended was that weirs should be constructed across the rivers and their principal affluents, and that supplies of water should be directed along effluent creeks, thus making use of the natural channels for distribution purposes. When natural channels were not available artificial distributaries were proposed, and a permanent supply was to be maintained by the construction of tanks and dams, which were to be filled from time to time from the distributaries. There is no doubt that, for the purpose of affording a supply of water for domestic purposes and for stock, the arrangements proposed

were

were the most economical which could have been devised. A striking instance of the splendid results accomplished by the works carried out is afforded by those of the Wimmera district. Until the end of last year the amount expended on the works in charge of the Wimmera United Waterworks Trust was about £130,000, and it is estimated by leading men in the district that the increase in value of the land due directly to the water supply provided is over a million sterling. Land which before the works were constructed could not be sold for more than 25s. per acre now readily brings from 50s. to 80s. per acre. Speaking generally for all the districts in the northern plains in which water has been supplied by the projects of Messrs. Gordon and Black, the direct result of this water supply has been an increase of £1 per acre on an average, on all the land benefiting by it.

Another most important result of these works has been the promotion of settlement on the land. Formerly, settlers of moderate means were reduced to the greatest straits, and in many cases ruined through want of water in dry seasons, and this occasionally happened in years when there was sufficient grass to maintain stock. In the Wimmera district in particular the attempt at settlement was considered a complete failure, and until the time when the water conservation works were initiated the settlers on small holdings were selling off their properties at a serious loss and leaving the district. The beneficial effects attending the opening of the works exceeded the most sanguine expectations. Small freeholders who had been endeavouring to sell their land at once relinquished such intentions, and not a few who had left the district returned and purchased land at enhanced rates. The effect of the works in the districts of the Loddon United Water Trust and the Echuca and Waranga Trust has been similar though perhaps less striking; but in all cases the results of these works for water conservation and supply have been to promote settlement, to increase production in a remarkable degree, and to greatly enhance the value of the land.

It seems now scarcely credible that when it was proposed to act on the recommendations of Messrs. Gordon and Black, and to proceed with the damming of rivers, the improvement of creeks, and the excavation of new channels, the projects were in many cases met with ridicule from the very persons who have benefited so largely from the works. The folly of the objections urged might be passed by, were it not that circumstances tend to show that similar objections would be raised by persons similarly situated in New South Wales. Of the objections raised, the only one which was even in a moderate degree plausible was that, on account of the dry and porous nature of the soil, any water diverted from the rivers would be lost before it could flow sufficiently far to be of any service. In the Wimmera district in particular it was alleged that, owing to the spongy nature of the subsoil, the effect of floods is perceptible in the increase of vegetation for two, or even in some cases three years, and the wildest conclusions regarding the absorptive power of the soil were based on this statement. Theorists who advanced such opinions entirely lost sight of the fact that canals running through alluvial soil naturally tamp up crevices in their beds and banks by the deposition of material in a finely-divided state, and that this has been borne out by experience in many countries. As was expected by those who were competent to judge, the loss of water from the channels has been almost inappreciable. Mr. Stuart Murray states that in some of the longest channels the loss does not exceed 10 per cent. on the whole length. The total length of the channels either constructed or improved by the Wimmera United Water Trust, until the end of 1885, was 318 miles, and this includes one of 64 miles in length, another of 60 miles, another of 48 miles, and a fourth of 40 miles. In every case the action of the channels has been satisfactory, so far as the small proportion of loss is concerned. Still, it is to be remembered that the channels in operation are main distributaries, and that in all cases where old creek beds could be made use of they have been brought into requisition. In the case of water running in channels of considerable size, or in old creek beds which have been subjected to a long process of natural puddling, the loss is much less in proportion than it would be in small channels of the description of irrigation laterals. Until the present, only channels of the former types have been brought into use, but it is expected that in the various Water Trust Districts the country will eventually be intersected in all directions by minor distributaries.

In the various projects which have been carried out for the water supply of the country districts, both public and private tanks for storage necessarily play an important

important part. As occasion requires, these tanks are filled from the distributaries, and those constructed at the public expense in the Wimmera district are in all cases fenced in, and are each provided with a force-pump. Troughs are provided for the use of stock, but no establishment is maintained; so that persons wishing to water stock must themselves pump the water. Owners of tanks are on application permitted to fill them whenever a supply can be spared; but such tank-owners who wish to obtain a supply from time to time from a distributary are required to pay the cost of a stop-gate on the distributary at the point of offtake. These stop-gates, which are simple and inexpensive in construction (*vide* plate), are provided with padlocks, which are opened only by employés of the Trust after the application for a supply has been granted. When the distributary is in cutting at the point of off-take the required supply is allowed to run over the bank, which is lowered on the upstream side of the stop-gate for this purpose; but when the distributary is in embankment a pipe outlet is used.

Having described the general principles on which the works for water supply in the northern plains of Victoria are constructed and managed, it remains to mention the more important details of some of the projects carried out in the districts visited by the Commission. The Wimmera scheme is the most important of these, in so far that it provides for the district which is most liable to severe droughts. The project as prepared by Messrs. Gordon & Black was designed to provide for a tract of country 2,750 square miles in extent; and, besides ordinary distribution channels and storage tanks, it included a cut uniting the east and west branches of the Wimmera, and another from this river to the Richardson. The works on the Wimmera are of special interest, on account of the general resemblance of the conditions existing on that river to those in the case of the Macquarie, the Narran, and other rivers and creeks in New South Wales. In the Wimmera we have an intermittent stream which depends on a hilly tract of country for its supply, but which flows chiefly through alluvial plains till it is lost in a series of swamps, or, in exceptionally wet seasons, till it reaches Lake Hindmarsh. Not only is there no reliable record that the flood-water of the Wimmera ever reached the Murray, but there is no proof that it has gone beyond Pine Plains, about 25 miles north of Lake Albacutya, and it has reached that place on only two or three occasions since the country was first explored. The two main streams—the eastern and western branches—which form the river Wimmera, above Longerenong, have catchment areas of 790 and 550 square miles respectively. Comparing this total catchment with the effective catchments of the Macquarie and the Namoi, we find that it is less than one-seventh of the former, and considerably less than one-third of the latter. In the hilly portion of the basin of the Macquarie the mean rainfall is over 23 inches, and in the corresponding portion of the basin of the Namoi it is nearly 22½ inches. From the available information, it appears doubtful whether the average rainfall on the upper parts of the basin of the Wimmera exceeds that of the Macquarie or the Namoi; and it may therefore be assumed that, roughly speaking, the discharge of these rivers is in proportion to their effective catchment areas. The Wimmera scheme, as already mentioned, was designed to afford a supply to an area of 2,750 square miles, and there is little doubt that expectation on this head will be realized if not exceeded. The tract of country between the Macquarie and the Bogan, which is at least as well adapted for the distribution and storage of water as the Wimmera district, is roughly 180 miles in length by 30 miles in width, or equal to an area of about 5,400 square miles. To supply this area with water, we have a river possessing a catchment more than seven times as great as that which can successfully supply an area of 2,750 square miles. In the short period during which the Wimmera works have been in operation they have, as we have shown, increased by one pound per acre the value of the land benefited; and it may reasonably be asked why equal results should not be obtained in this Colony by similar works on the Macquarie and other similar rivers. Supposing that the works in the Wimmera district will cost altogether £150,000—and there is no reason to suppose that that amount will be exceeded—there is every reason to conclude that works can be constructed on the Macquarie at double that amount which will give double the supply. Judging, then, from the result achieved in the Wimmera district, it is a fair conclusion that a judicious expenditure of £300,000 in diverting supplies from the Macquarie and distributing them through the district between that river and the Bogan would result

result in increasing the value of the land by about 3½ millions sterling. The Macquarie is only one of a large number of rivers of New South Wales which could be dealt with in the same manner as the Wimmera.

The principal weirs on the Wimmera, are the Dunmunkle Weir, at Glenorchy, which holds back the water to a distance of about 3 miles, and diverts a supply down Swede's Creek and Dunmunkle Creek; the Ashen's and Tarrambac Weirs, which divert supplies into the corresponding creeks bearing these names; and the Doven Weir, near Horsham, which is intended to provide a supply for a tract of land about 200 square miles in extent, and having a general level of about 50 feet above the river. The most important part of all these weirs is a timber framework, and this is backed by a filling of puddle and earth. The falling water in some cases, as at the Dunmunkle Weir, expends its force on a water cushion; while in others, as at Doven, the force of the water is broken by a series of timber steps. The excellent though primitive method of raising the crests of the weirs by drop-bars is generally adopted. The bars in these cases are strong battens, which fit into timber grooves, and are easily lifted by hooks provided for this purpose.

This style of construction, besides being admirably suited to sites where, as in the Wimmera district, rock foundations cannot be obtained, has also the advantages of economy and simplicity. Such weirs can be built by ordinary workmen without any expensive appliances, and from materials obtainable in the neighbourhood. Three of the Wimmera weirs—the Doven, the Longerenong, and the Yarrambiac—are shown in detail in the appended plates. These are selected not as the most important, but as being probably the best examples of this style of construction. The Doven Weir in particular is considered a model of its class. The Dunmunkle Weir, the most costly, and one of the most important in the Wimmera district, has a crest length of 290 feet, raises the level of the river to 19 feet above the bed, and is capable of passing 8,000 cubic feet per second before the banks would be overflowed; but it cannot be considered in any way an example, as material alterations and repairs had to be made on two different occasions.

The skeleton plan of the Wimmera district (*vide* plate), showing the manner in which the country is being covered with a network of channels, gives an excellent idea of the great work done by a very limited supply of water. All these works are managed, and the majority of them have been constructed by the Wimmera United Waterwork Trust, whose jurisdiction includes the whole of the Wimmera River from above Glenorchy. Questions regarding the payment of rates for the water supplied are still in an unsettled state; but in the case of public tanks, and of the arrangements for supplying water from them, the cost of maintenance is paid by the Shire Council.

In the Loddon scheme which, as originally designed, was intended to provide for a district of 1,273 square miles in extent, the leading feature is the massive concrete weir across that river at Bridgewater. The site selected for this weir is a dyke or a bar of basaltic rock extending across the river, and which already formed a natural dam. This is a style of foundation which can be obtained on several of the rivers of this Colony, and particularly on the Darling. The Bridgewater Weir, the general plan and the cross section of which are shown in the Appendix, is used not only to divert a supply for stock purposes, but also to provide water power for a flour-mill situated a short distance down the river. The power thus obtained, and which is made available by the use of two turbines, is a mere fraction of that which could be made available on the Barwon at Brewarrina. The actual area of the Loddon United Trust District is 704,000 acres and the extent provided for by the work in existence is about 500,000 acres. It should be remembered that this provision of permanent water for half a million acres of land is made from a supply which was formerly lost entirely in ordinary seasons before it could reach the River Murray. Not only so, but the catchment area from which the supply is obtained is less than one-fifth that of the Macquarie at Dubbo, and considerably less than half that of the Namoi at Gunnedah.

The principal work carried out by the Loddon United Water Works Trust, in addition to the Bridgewater Weir and the channels depending on it, are the Kinypaniel Weir and the supply channels, which, in conjunction with the Kinypaniel Creek, conduct the waters of the Loddon to a series of lakes in which a permanent supply is by these means maintained. The Kinypaniel Weir, like those constructed by the Wimmera Trust, is of timber, and is provided with a scouring channel

 through

through the centre of the weir. A cross section of the weir along the centre line of the channel is given in the Appendix. The general arrangements of the Loddon, Campaspe, and Gunbower Schemes, and the extent to which the districts benefited by them are being covered with a network of distributaries, are shown in the skeleton plan given in the Appendix.

The work carried out, or proposed, in the Echuca and Waranga Water Works Trust District are of great interest on account of the successful work already done, but much more so on account of the importance of the object aimed at. At present the entire supply of water is obtained by pumping from the Goulburn River, near Murchison, and the system of distribution includes 80 miles of main channel and 110 miles of minor distributaries—the most important of the latter being the Wanalta Channel, which is 34 miles in length. The pumping machinery consists of two 26-inch centrifugal pumps, which were guaranteed to deliver 20 million gallons per day of 24 hours. These pumps are worked by compound engines which develop 230 indicated horse power. The total cost of the pumps and machinery in position was £7,000, and the cost of working, exclusive of interest on the plant, is reckoned at from £1,800 to £2,000 per annum. The pumps are actually delivering 40 cubic feet per second, and if it be assumed that they work sixteen hours per day, and 240 days in the year, the total quantity delivered in one year will be 552,960,000 cubic feet. It will be fairly correct to set down the gross cost of working at £2,000 per annum, and at this rate the cost of pumping will be at the rate of 13,824 cubic feet for one shilling, or 7,200 gallons for one penny.

While in the Wimmera scheme the natural channels are utilized to a very large extent as distributaries, the distributaries of the Goulburn supply are all artificial with the exception of a portion of the Wanalta Channel. The reason for this difference is obvious. In the Wimmera District irrigation except on a very limited scale, is impossible on account of the insufficiency of the supply of water; whereas in the Echuca and Waranga Trust Districts irrigation is intended to be carried out on a very extensive scale, so that in the construction of distributaries it was necessary to have them aligned, with this object in view. Besides, natural channels were not available to the same extent for the distribution of the Goulburn water as they were in the case of the Wimmera. The channels at present in use or under construction, are estimated to afford an ample supply for domestic and stock purposes throughout the Trust District, which includes an area of over 1,000 square miles, and to furnish in addition sufficient water for the irrigation of from 7,000 to 10,000 acres. Up to the present only a very small area has been irrigated, but as much as could be expected under the partially developed state of the work. Almost the whole of the water has been used for supplying public and private tanks. Of the former class a large number has been constructed, at a cost of several thousand pounds, by the shires of Echuca and Waranga; and these tanks have been fitted with water-lifts of various forms, as well as with troughs for the supply of stock, and pipes and shoots for filling water-carts. The results effected by the work throughout this Trust District are best described in the words of Mr. Walter Scott Murray, C.E., Engineer to the Trust, who has very kindly supplied a large amount of valuable information regarding them. Mr. Murray, on 11th March of the present year, writes as follows:—"Every summer since the country has been settled the selectors have had to depend upon the public tanks and wells, and often they have been compelled to abandon their homes for several months in the summer, and camp with their families and stock on the Goulburn. This now is done, and, except in a few instances which will soon be attended to, no man in the worst season will have more than 2 or 3 miles at the very outside to travel to obtain a splendid supply of water. Of course being in such close proximity as that to the channel it may be readily imagined that the cost of constructing small supply channels by the farmers to fill their dams is very trifling. In one instance, near Corop, there is a training stable, the proprietor of which spent last year £75, and the year before £120, in carting water. This year his dam went dry, and at an outlay of about £7 he conveyed water from our main channel to his dam twice, the distance being 1½ miles. The effect of the construction of the work has been to raise the value of the land throughout the whole district by an average of £1 per acre. Where farms are in close proximity—say 1 mile—to a channel, the value has been raised by £2 to £3. Where channels intersect farms, land that would once bring £3 per acre, has sold recently

recently as high as £7." These results are all the more surprising when it is considered that the works are in an incomplete state, and that in fact they constitute a comparatively small portion of by far the finest irrigation scheme which has yet been matured in these Colonies. This project includes the construction of a weir across the Goulburn at a short distance from the present pumping station near Murchison, and of a main canal capable of carrying 68,500 cubic feet per minute. The plan (*vide* Appendix) showing the various channels now in existence, or under construction, affords a good idea of the general arrangements of the branches and distribution channels of the proposed project. Although the present supply is obtained entirely by pumping, and is used so far for stock and domestic purposes only, the ultimate object of the great project is kept in view as far as possible, so that the present channels will in nearly every case be utilized when the project is carried out. One point not indicated in the plan is the important part which the Waranga Basin will play in storing water for summer irrigation. In the preparation of the project, Messrs. Gordon and Black estimated that, of the total discharge of 68,500 cubic feet per minute which they proposed to provide for, 17,500 cubic feet per minute would be required to fill the Waranga Basin, leaving a balance of 51,000 cubic feet per minute for winter irrigation. The Warranga Basin is a large shallow depression similar in general characteristics to many of the so-called "lakes" of this Colony. Its area is about 7,000 acres, and its total available capacity 4,381 millions of cubic feet, or about 27,381 millions of gallons. It is estimated that the supply thus stored in the winter months will be sufficient to irrigate about 39,000 acres of summer crops. This added to 30,000 acres irrigated by the summer supply from the river gives a total of 69,000 acres as the estimated extent of summer irrigation. In winter the supply of 51,000 cubic feet per minute which will remain after allowing for the filling of the Waranga Basin will, according to the estimate of Messrs. Gordon and Black, suffice for the irrigation of 204,000 acres.

In describing the conditions and functions of the present water supply from the Goulburn, it has been mentioned that the channels are, as a rule, laid out with the ultimate view to their being utilized as irrigation distributaries, and that they are therefore, with one exception, artificial. In the case of the Wanalta Creek, where the natural channel has been utilized to a considerable extent several important results have been accomplished. In the first place, with the aid partly of a regulating weir and partly of a supply from the main channel of the present works, a permanent supply is secured for all land within easy distance of the creek. In the second place, by deepening the creek or making a new channel the extensive flats on its lower reaches, which were formerly inundated by floods, are now drained, and the land thus improved made available for constant use. In the third place, by the same arrangements the natural drainage carried by the creek, and which formerly caused much mischief without affording much benefit, is now distributed and stored for use during dry periods. The weir and regulator in the Wanalta Creek has been in every way a most successful work. The main channel from the pumping station on the Goulburn conducts a supply into the creek above the weir, and is continued on the opposite side of the creek. The water in the latter is held back by the weir to a distance of about 6 miles, and regulating sluices in the weir provide a regular supply along the lower portions of the creek. In the design of the weir Mr. Stuart Murray, judging by the data then available, estimated that the highest floods would not give a depth of more than 2 feet over its crest; but on one occasion since its erection 25 inches has passed over, this being equal to a discharge of about 250,000 cubic feet per minute. That the weir, which is constructed of timber obtained in the neighbourhood, stood this test without any damage whatever speaks highly for both its design and construction.

These facts regarding the Wanalta Creek have peculiar significance when compared with conditions existing in New South Wales. It is beyond question that the most common type of creek throughout the west of this Colony is that which is intermittent, and the supply in which is lost in swamps or other tracts of low land. Instances of this type naturally vary greatly in size and importance—the Narran and the Paroo being striking examples of the largest class. In the case of the Wanalta Creek the natural drainage is supplemented from the Goulburn. A similar arrangement could be carried out in connection with any of our large rivers, and where only the intermittent rivers or creeks are found, the absence of a permanent stream could be compensated for by the provision of tanks and dams of increased capacity.

The

The information acquired, and the experience gained, in connection with the construction and management of the works for the water supply of Melbourne, are of great value, not merely for the guidance of other cities, but on account of the light which they throw on the general question of the utilization of water. A circumstance which lends additional interest to these works is that a portion of the supply is carried across the Main Dividing Range, thus affording in a double sense a precedent for the diversion of the Snowy River in this Colony, as suggested by Mr. Adams, the Surveyor General.

The catchment area on which the present supply of Melbourne depends is about 53,000 acres, of which extent 40,000 acres is on the southern slopes of the Plenty Ranges and 13,000 acres on the northern. The great proportion of the catchment area is of a very favourable description for impounding a supply, the central mass and northern spurs of the range being granite, while the flanks of the range are chiefly of schistose rocks. The great depth of permeable surface soil ensures the preservation of a large proportion of the rainfall and its steady flow to lower levels, while the granite and schistose rock prevent any loss of the natural supply by underground percolation. The proposed extension of the works, by impounding a supply from Watts River and from Graceburn and Corranderk Creek, will enlarge the catchment area by about 45,000 acres, making altogether a catchment of 98,000 acres, or considerably less than half the area on which the new Sydney Water Supply Works will depend. The catchment of the Watts River is porphyritic country, with spongy soil and springs in all directions.

The storage reservoir at Yan Yean, about 20 miles from Melbourne, has a total capacity of 6,400 millions of gallons, and an available capacity of 5,300 millions of gallons. The corresponding figures for the Prospect Reservoir for the supply of Sydney are 10,635 millions and 7,110 millions. In connection with the Watts River Scheme, Mr. W. Davidson, Superintending Engineer in charge of the Yan Yean Works, has proposed that a second storage reservoir should be constructed; and though no steps have been taken to carry out this project, there is little doubt that the question will have to be considered within the next few years. Mr. Davidson has found a site at which, with a masonry dam 105 feet in height, and 11 chains in length on the crest, the storage capacity in the upper 25 feet of the reservoir will be 2,000 millions of gallons. A general plan of the works is given in the Appendix, but, in addition, the following figures, kindly supplied by Mr. Davidson, will be of interest:—

Present Works.

	Miles.
Open channel	19
„ in course of construction	10
Mains, not including city mains	70
„ 30", in course of manufacture	6½

Proposed Extensions.

Open channel	31
Piping, inverted syphons	6½
Tunnels	8

The discharging capacity of the channels in the present works is as follows:—

	Million gallons per diem.
Silver Creek channel—in course of construction	12
Wallaby Creek channel	30
Clear Water channel	120
Yan Yean—Morang channel	34

The proposed Watts River canal and tunnels will be excavated to such dimensions as will deliver a supply of 56 million gallons per diem; but lining of channels wherever necessary will be put in for a supply of 25 million gallons only, and the syphons will also be designed to discharge at this rate. On the whole, Mr. Davidson estimates that the supply from Watts River, together with that obtainable from various creeks, would amount to 100 million gallons per diem, and this altogether in addition to the supply available from the present works.

Under present circumstances the Yan Yean mains will deliver 33 million gallons per diem, which is 7 millions more than the greatest demand for one day which they have yet had to sustain.

The experience gained on the Yan Yean works has furnished a valuable contribution to the knowledge of the relative values of open channels and iron pipes. Some time ago there was an urgent demand for an increased supply; and in order to meet

meet this demand with the least possible delay it was decided to take up some miles of main, substitute an open channel of much greater discharging capacity, and use the pipes thus made available in duplicating the line lower down. This method of increasing the supply was promptly adopted, and not only did it prove highly economical, but in addition the quality of the water was perceptibly improved.

Although the visit of Mr. Deakin to America had special reference to irrigation, one of the most striking results of his report has been a saving of about £27,000 on one contract in connection with the Melbourne Water Supply. Mr. Deakin, in his report, called prominent attention to the extensive use of wrought iron instead of cast iron for pipes in Western America, and to the undoubted advantages of this practice. On account of this, when a contract for the supply of iron pipes for the Yan Yean Supply had to be let, soon after the issue of the report, it was decided to call for tenders for pipes of wrought iron. The result was that, instead of an outlay of about £62,000 being required for cast iron pipes of the usual description, the contract was let for £35,000 for wrought iron pipes of the same discharging capacity. Considering that wrought iron pipes of equal strength are much lighter than those of cast iron—that they are much cheaper for the same discharging capacity—that there is no risk of fracture, and that a broken pipe is easily repaired—it seems surprising that wrought iron pipes have not been more generally adopted. In the Appendix will be found the specification for the wrought iron pipes which are to be used on the Yan Yean Works. That portion of the specification regarding the preservation of the pipes by the use of a mixture of tar and asphaltum is worthy of attention, as this is a point to which Mr. Davidson, the Superintending Engineer, has devoted much care and attention.

The works connected with the Melbourne Water Supply are of the most substantial character throughout. Masonry and pitching of granite, set in cement, constitute the lining generally adopted in the channels. The various cross sections of the channels, as well as the rate of fall, are given in the Appendix. In the case of the section in "wet granite detritus," on the Silver Creek Conduit, the style of the cross-section and the material used were adopted as the most economical under the contract rates. One of the most remarkable of the works for the supply of Melbourne is the 51 feet drop on the Clear Water channel. Chiefly on the ground of economy, the difficulty occasioned by a sudden fall on the line of conduit is surmounted by laying a 30-inch main 7 chains in length, and with a fall of 51 feet. The entire supply for Melbourne passes through this 30-inch main, and while as a spectacle the effect is impressive, the waste of so much water power seems out of keeping with Victorian enterprise.

The Coliban Water Supply scheme was designed to meet the domestic and mining requirements of several important towns, as well as of a number of mining townships scattered over a large extent of country. The supply is obtained from the Coliban River, which rises in the Main Dividing Range and flows into the Campaspe. The storage reservoir is situated near Malmesbury, in the valley of the Coliban, and is capable of containing about 3,000 million gallons. Mr. C. W. Langtree, Secretary for Mines and Water Supply in Victoria, has very kindly supplied, among other information, a general plan of the scheme, a table giving interesting details regarding the various reservoirs, &c., and a "Statement of the Rules and Regulations of the Castlemaine and Sandhurst Water Supply District." These papers *(vide* Appendix) afford such complete information regarding the Coliban scheme and its working that little explanation is required in addition. The main channel from Malmesbury to Sandhurst is 42½ miles in length, and there are, in addition, 165 miles of distributing and sluicing races. For the first 18 miles from Malmesbury the main channel has a bed-width of 5 feet, a depth of 5 feet, side-slopes of 1 to 1, and a fall of 3½ feet per mile. For the remaining distance to Sandhurst it has a depth of 4 feet and a fall at the rate of 5 feet per mile, the other conditions remaining the same as in the first length. The distributing and sluicing races vary from 3 to 6 square feet in sectional area, and have falls ranging from 4 to 6 feet per mile. There is a series of drops along the line from the main channel, which would yield altogether 403-horse power, but no use has yet been made of this power for manufacturing or other purposes.

Although Sandhurst depends almost entirely on the Coliban scheme for its water supply, a considerable quantity of water is impounded in the Crusoe and Big Hill reservoirs from the catchment areas above them. Regarding these reservoirs

and

and their drainage areas Mr. C. W. Langtree writes as follows:—"The drainage areas proper of the Big Hill and Crusoe reservoirs are limited in extent, and their surfaces have to a large extent been broken up by mining operations; the effect of which is that the water collected therefrom is charged with large quantities of clayey matter, which can only be got rid of by lime treatment. For this purpose lime settling and clear-water ponds are included in the appendages of both reservoirs. The rainfall over Big Hill Reservoir watershed is conveyed by an intercepting channel clear of the reservoir, in order that the comparative purity of the Coliban water stored therein may be maintained, and thus obviate the necessity of the lime treatment."

The Coliban Works furnish an instance of the supply of a series of towns and mining settlements from one comprehensive scheme. Although the direct net return from these works is only about $1\frac{1}{5}$ per cent., the benefits conferred by the scheme have been enormous; in fact, without the Coliban scheme, the present advanced state of development of the mining and other industries throughout the Sandhurst and Castlemaine districts would have been impossible. Although the works must still be considered as only partially developed, it is a question whether, even in their present state, they would not have afforded a fair direct return if the mistakes which occurred in the course of their construction had been avoided. It is believed that by the construction of a dam about 95 feet in height, at a distance of 8 miles above that at Malmesbury, 10,000 million gallons of water can be stored; and, if this work be carried out, not only will additional security be afforded to Sandhurst and Castlemaine, but it is probable that, after ample allowance for domestic mining, and manufacturing purposes, a supply will be available for irrigation on a small scale. This Upper Coliban Reservoir, if it can be constructed at a moderate cost, should greatly improve the financial position of the entire scheme.

In our previous Report we drew the attention of your Excellency to the steps which have been taken by the Government and public bodies of Victoria for the conservation of water in that Colony; and now that we have had an opportunity of personally inspecting several of the principal works for the conservation and distribution of water in their arid northern areas, we are more than ever convinced of the wisdom of the course upon which our neighbours have entered, and of its thorough adaptability to meet many of the requirements of our own territory. Upwards of half a million sterling has been expended, with the result that extensive tracts have been again brought into profitable use which had been rendered desolate and uninhabitable from the want of water, and wherever irrigation has been attempted it has been followed by the most satisfactory results. Much as has been accomplished, however, in Victoria, the Government and people of that Colony are not by any means disposed to be satisfied with the amount of success which has been attained, but they recognize more fully than before that the prosperity and increase of population must depend in a very large measure upon the means which they adopt for the conservation and utilization of the rainfall. They are preparing to bend all their efforts to the accomplishment of this object to the fullest extent practicable; and if it should turn out that the anticipations of their Government are realized, namely, that it is possible to irrigate a million acres of land in Victoria, the increased productiveness of the soil under that condition of cultivation will, we anticipate, be equivalent to increasing the present productiveness of her territory to the extent of at least twenty millions of acres.

We have been very favourably impressed by the provision which has been so generally made throughout Victoria for the supply of water to towns. While large cities, such as Bathurst, Goulburn, Maitland, and Newcastle, have been for many years without a water supply, we observe that many of the small, and, by comparison of numbers with old established communities in New South Wales, insignificant towns, were provided with an abundant supply of good water; and we could not but regret that so much remains to be done to overtake the wants of our urban population in this respect. It is hardly conceivable that in any part of the globe the natural conditions of life can be more favourable to health than in the salubrious climate of this Colony; and yet, owing as we believe to neglect in providing a supply of pure water, both in the towns and in the rural districts, typhoid fever and other diseases have increased to an abnormal and an alarming extent. There are scores of towns in New South Wales which could be supplied with water, at a cost the interest of which could be easily borne by the inhabitants; indeed, the strong probability

probability is that an amount larger than would be sufficient under a water rate is now paid for carting water from sources where no precautions are taken to guard against pollution. Along the banks of the Hawkesbury, the Hunter, and other rivers, there are groups of towns which, there is good reason to believe, might be supplied with water from works designed to meet the requirements for stock and irrigation of the districts in which they are situated; and we anticipate that it will be found expedient and economical to provide for the requirements of towns in the systems of water supply which may be devised for the benefit of the rural population. The greater progress which has been made in this direction in Victoria is no doubt attributable to the system of local government which has so long obtained in that Colony; but it may be expected that similar results will follow here, when the Legislature shall have made legal provision under which the intelligence and wealth of the country can be organized for purposes of self-help, and shall have impressed upon the inhabitants of particular districts the obligation to make the local improvements which they desire to obtain.

We have the honor to be,
Your Excellency's most obedient servants,

APPENDIX TO THE SECOND REPORT OF THE COMMISSIONERS.

ROYAL COMMISSION—CONSERVATION OF WATER.

REPORT ON THE GUNBOWER AND OTHER WORKS, BY THE ENGINEER TO THE COMMISSION.

IN pursuance of the instructions of the Commission to visit and report on such important Victorian works as the Members of the Commission had not an opportunity of examining, I proceeded to the Gunbower District, to ascertain the extent to which irrigation is carried on, the methods adopted, and the degree of success attained.

It may be explained at the outset that the Murray is the source from which the water is obtained for irrigation throughout this part of Victoria, although it is intended to utilize in the Swan Hill Trust District any supply of water which can be spared from the Loddon and Campaspe schemes. In some cases the supply is pumped direct from that river, but as a rule it is obtained from the flood-water which overflows from it and becomes stored in the Gunbower and other creeks, and in such depressions as Kow Swamp. The distribution of the flood-water is doubly aided by the configuration of the country. While the general fall of the district is at an average rate of about 9 inches per mile and in the direction of the Murray, there is also a fall in the ground to a moderate distance at right angles with the river bank.

The Gunbower, like the Tuppal and other creeks on the New South Wales side of the Murray, is small in section at the offtake from the river, and, like them, becomes greatly enlarged in section as the distance from the river increases. Although at and near the head it has been deepened, and its sides dressed off roughly to slopes of about 1½ to 1, still its bed width at this part does not average more than 7 feet, while its depth varies from 10 feet down to about 3 feet. The course of the Gunbower Creek too is very tortuous, so that altogether considered as a distributary, the portion near the head is inferior to the Yanko Creek. The former, however, increases greatly in section, so that at a distance of about 3 miles from the head it is from 50 to 60 feet wide, and from 6 to 9 feet deep. At intervals on the creek there are broad and deep lagoons, the supply in which remains so uniform as to suggest the idea that a portion of it is due to percolation. At one of these lagoons is erected the pumping machinery which raises water for irrigation on the Gunbower Station of Messrs. Booth & Co. As the Tuppal Creek derives a supply from several places many miles downstream from its head before any water flows in at the head itself, so the Gunbower Creek derives a supply first from Deep Creek and next from Bagot's Creek, and from the creek head only in unusually high floods. It is reckoned that the flood-water requires to be flowing from the Murray with a depth of 6 feet in Deep Creek and of 4 feet in Bagot's Creek before any can pass in at the head of the Gunbower. Of these outlets, Deep Creek has been dressed off to a section 10 feet wide at the bottom, and with side slopes of 1 to 1. The bed at the offtake from the Murray is 12 feet below the level of the flood of 17th December, 1884, and the rate of fall in the

channel is 1 foot 4 inches per mile. The length of the improved part is about 3¼ miles, but the creek is further improved by making straight cuts across bends and putting in a stop-gate. The amount already spent in improving Deep Creek is about £600, with the result that the flood-water now flows into it when the gauge at Echuca reads 6 ft. 6 in. above what is there termed "summer level." Bagot's Creek also has been improved, the bed width having been made 12 feet, and the side slopes 1½ to 1. In ordinary high floods the outflow from the Murray through it will be 7 feet in depth. The fall in the first 3¾ miles is at the rate of 2 feet per mile; but beyond that distance, towards Kow Swamp the fall ceases, and parts of the creek bed are so high that the effective fall in a length of 6 miles is under 5 feet. In addition to the Gunbower Creek head, which has already been described, and the two important outlets above mentioned, a new outlet is proposed, with a bed width of 10 feet, side slopes of 1 to 1, and a fall of 9 inches per mile. The depth of water in this cut at ordinary high floods will be slightly over 9 feet. The length of cutting to be done in this case is 2 miles 3 chains.

The quantity of water diverted from the river Murray by existing works, or proposed to be diverted by works which have been designed, is a matter of great importance. It would appear that during an ordinary flood the outflow in Deep Creek is 9 feet in depth; in Bagot's Creek 7 feet, and at the head of Gunbower Creek 3 feet. The depth at corresponding periods in the proposed new cut will be 9 feet. Making allowance for the rough state of the present outlets, and including the quantity which the new cut will carry, I believe that on a fair estimate the total supply which will thus be diverted in an ordinary flood will not fall short of 1,000 cubic feet per second, and the discharge of the outlets can be increased by keeping them in good order.

In the course of my inspection of the irrigation operations in the Gunbower District, three subjects in particular claimed my attention: 1st, the description of machinery used for raising the water; 2nd, the methods adopted for laying out and constructing distributaries; and 3rd, the agricultural operations and the general management of the irrigation.

The small lifts which are obtainable throughout a great portion of the Gunbower District are favourable to the use of centrifugal pumps, which are here invariably used for irrigation purposes. As an example of irrigating plant of a high order, that at the Gunbower Station demands special mention. There is a compound condensing engine of 40 horse-power nominal, by Robison Brothers of Melbourne. This engine works an 18-inch centrifugal pump by the same makers. The suction-pipe, which has no foot-valve, is tapered out to 22 inches in diameter at the bottom. This machinery furnishes the main supply for irrigation, but in addition to it, two portable engines, one of 10 and the other of 12-horse power, are occasionally used to irrigate isolated patches of land whenever required. The machinery used by Mr. G. R. Hayes, of Bandon Park, Torumberry, for the irrigation of his land, is about equal in power with that at the Gunbower Station. Mr. Hayes' engine, which is also of 40-horse power nominal, is fixed on the bank of the Murray, and the pump well is connected with the river by a timbered drive—6 feet by 5 feet. The well, which goes down to the level of the river bed, is 14 feet by 7 feet, and is intended for two 18-inch centrifugal pumps, but only one has actually been used. Mr. John Garden, J.P., of Cohuna, who was the first to call public attention to actual proofs of the benefits of irrigation in northern Victoria (see Melbourne *Argus* of 11 November, 1882), uses a 10-horse power engine and a 15-inch centrifugal pump, and irrigates from 300 to 400 acres of cereals, and about double that area of grass land. It is necessary to state, however, that in his case the lift is only about 5 feet. Mr. W. J. W. Patchell, of Kerang, who has practised irrigation since 1863, used an ordinary Californian pump for the first two seasons, and after that a McComas water-lifter, but he adopted the centrifugal pump nearly twenty years ago, and has made use of it ever since then.

In connection with this question of pumping machinery, I may mention that when I was in Echuca Mr. Whitehead, mechanical engineer of that place, very kindly showed me the plans of a barge built by him, and on which he had erected pumping machinery for use on the Murrumbidgee, at Mr. Fitzwilliam Wentworth's Burrabogie Station. This pumping machinery consists of one of Messrs. J. and H. Gwynne's "Invincible" patent compound direct-acting centrifugal pumping engines, and is capable of raising from 4,000 to 5,000 gallons per minute to a height of 40 feet.

feet. The intention is to provide for the raising of a supply of water for irrigation or for stock purposes at any place it may be required along the river frontage. Both the machinery and the barge have been tested by use, and have shown that they satisfactorily fulfil the conditions required of them. I was informed that the arrangement adopted by Mr. Wentworth on the Murrumbidgee is to be followed in at least one case on the Murray, near Echuca, and that a barge has been constructed, and pumping machinery ordered, for this purpose.

When irrigating by means of a centrifugal pump, the rush of water near the outlet of the delivery pipe necessitates precautions for the protection of the channel near that place. The general course adopted is to deliver the water into a timber shoot, and to give the distribution channel an enlarged section at and near this shoot.

The subject of the distribution of water for irrigation is one in regard to which great advances have been made in Victoria, and, in some cases at least, the improved system followed is the result of dearly-bought experience. A point which is particularly worthy of note is the fact that on every holding where any considerable area is under irrigation, cross sections of the land irrigated or intended to be irrigated have been taken, at such intervals as to enable the occupier to align his distributaries in a suitable and scientific manner. At first irrigators believed that such leveling was unnecessary, but they soon found that this opinion led to expensive mistakes. In the property of Mr. Hayes, at Torumberry, there is one main distributary $2\frac{1}{2}$ miles in length, and from it about 12 miles of laterals or branch channels. The main distributary is about 10 feet wide at the bed, 25 feet at the ground level, and about 40 feet between the tops of the banks. For the irrigation of cereals the laterals are in this case made at intervals of 100 yards, and each lateral is intended to irrigate 25 acres; but for the irrigation of the native grasses the intervals between the laterals are much greater. The outlets from the main channel to the laterals consist of hollow logs laid through the channel banks. The intake end of each log is kept closed with boards except when water is required. The system followed in carrying out irrigation is to pump up a sufficient supply to fill the main channel to a height of from 1 to 3 feet above the ground level, and then to open the outlets in succession as the flooding of the land proceeds. A somewhat similar system is followed on the Gunbower Station, but in other cases the flooding is done direct from the main distributaries without the intervention of laterals. Excepting in the case of grass land, this arrangement is too wasteful to be long persisted in. On this point it is necessary to refer to a statement made in Mr. Derry's Report to the Victorian Water Commission. On page 43 of that report Mr. James, an American irrigation engineer, is represented as stating that irrigation from "branch drains" instead of from larger distributaries "would require six times the labour, and consume twice as much water, and be of no advantage to the crop." This statement is probably correct as applied to the particular case to which it referred, but it is altogether at variance with the results of ordinary experience. In the case referred to by Mr. James, the "contour checks" or divisions of the land are about 20 acres each in area, and the distributaries are taken off the main canal at uniform intervals of a quarter of a mile. While this system is probably suitable under certain circumstances, the statement that irrigation conducted by flooding from laterals would require six times as much labour is certainly an exaggeration, and the other two statements, namely, that twice as much water would be required, and that there would be no advantge to the crop, are exactly the reverse of general experience. So well has it been established that the division of fields into small compartments is productive of economy in the use of water, that in some at least of the provinces of India, the size of the "kiyari," as an irrigation compartment of a field is termed, is limited by special regulations sanctioned by Government. The most recent investigations tend to show that under ordinary circumstances about one-eighth to one-tenth of an acre is the best area for a "kiyari" so far as economy of water is concerned. The conclusion that small divisions of the land give the best results with the lowest supply of water has been arrived at wherever irrigation has been long practised, and a good instance of this can be found in Victoria. Mr. Patchell, of Kerang, whose experience of irrigation, as already mentioned, extends over twenty years, has found by actual observations on his own land that a considerably smaller supply of water will suffice when the land is divided into small compartments, and that, in addition, the crops are much more even in their growth. It must, however, be understood that while in the case of ground which has been

broken

broken up the saving in water effected by the use of small compartments is very important, it is different with grass land, where the soil is compact and unbroken. In irrigation under the latter circumstances, the loss of water caused by flooding large areas of fairly level land is so slight that it would not be worth the trouble to portion off the land into "checks" of small or even moderate dimensions.

The excavation of main distributaries is done with the plough and scoop, and that of the laterals with the ordinary plough and the V plough. One scoop which I measured, and which I was informed is about the most common size in use, was 2 feet 10 inches wide by 3 feet 2 inches long, and removed about one-third of a cubic yard at a time. Scoops of this description were, at the time of my visit, being used on a contract for the excavation of 7 miles of channel for the Wimmera United Waterworks Trust near Murtoa. This channel was to be 4 feet in width at the bottom, and to have side slopes of 1 to 1. The depth of cutting throughout 5 miles of the contract was only from 2 feet to 4 feet, but, in the remaining 2 miles it ranged from 5 feet to 9 feet. No part of the spoil bank was to be within 3 feet of the edge of the cutting. Considering that the wages of a labourer at Murtoa range from 8s. to 9s. per day, the contract rate of 9d. per cubic yard for the excavation of this channel, including the dressing of the slopes, appears very moderate. That the dressing of 1 to 1 slopes merely by expert use of the scoop can be done with neatness and uniformity is a fact of which I had ample evidence, both in the Wimmera and the Echuca and Waranga Trusts. The main distributaries excavated by private individuals for irrigation purposes are made with the same class of implements as are used by the Trusts, but the work is done in a much inferior style. This appears to be partly due to a mistaken idea that an improved style of distributary would mean useless expense. In reality, the roughly constructed distributaries, with side slopes of 2 or 3 to 1, or even flatter, are far more expensive in the end than those which are made scientifically at a slightly greater first cost. This is easily understood when the following facts are borne in mind:—(1) That a distributary is frequently empty for some time, and that every time it is supplied great loss of water occurs by absorption in the bed and banks; (2) that the loss by absorption is in proportion to the wetted area; and (3) that the land occupied by a distributary is lost for agricultural purposes. Thus, in the case of a distributary whose top width is 33 feet, while it ought to be only $16\frac{1}{2}$ feet—and I have seen cases quite as bad as this—there is a loss of 2 acres of land for every mile of distributary, in addition to the increased loss of water by absorption and evaporation. Although the subject of the distribution of water in the country districts in Victoria is still in its infancy, rapid advances are being made in regard to it. The principle of designing channels so that the water will have the maximum velocity which the soil will satisfactorily bear is now being adopted in works carried out by the Trusts. In the Echuca and Waranga Trust District, this velocity is considered to be about 140 feet per minute. Following out this principle, what appear at first sight as very rapid rates of fall for channels excavated in earth have in some cases been adopted, in the Wimmera Trust District, by Mr. A. G. Brown, the Trust Engineer. In one case a channel having a bed width of 3 feet has a fall of 7 feet per mile, and in another case a channel of 6 feet bed width has a fall of 9 feet per mile. No scouring has taken place in either channel, which is only natural when it is considered that the depth of water flowing in them is only from 12 to 18 inches. Taking a depth of one foot for the larger channel and 18 inches for the smaller, it is found that the respective velocities are only 1·60 feet per second and 1·63 feet per second. It is evident from these figures that if the depths of water do not exceed those assumed, the Engineer might safely have adopted even greater rates of fall.

In the particular instance of American irrigation already referred to, it is mentioned that the distributaries are taken off the main canal at uniform intervals of a quarter of a mile. This arrangement is one which could not be imitated with advantage except under most unusual circumstances. The main watershed and valley lines which constitute the leading natural features of a country have their subordinate or branch ridge and valley lines, and these again are divided in the same manner. These natural features become less distinct as the land becomes flatter, and also as the rainfall diminishes; but still they exist, and they can and should be found in all projects for irrigation. It should not be necessary to point out that Nature does not make ridge and valley lines at regular intervals, yet the construction of irrigation distributaries at equal intervals practically ignores this truism. In the early days

of

of scientific irrigation in India, when an oversight of this description was perhaps to some extent excusable, distributaries were in some instances aligned without sufficient investigation as to the position of contours. The result was that such distributaries were, by comparison, both expensive and ineffective, and that in some instances new distributaries on more advantageous lines had to be constructed in their stead. The accompanying sketch plan (see Appendix) shows a portion of the Etawah Branch of the Ganges Canal, with some of the old distributaries and the new ones proposed to take their places. The contour lines show at a glance the necessity for the proposed alteration.

As already mentioned, the laterals are excavated by means of the ordinary plough and the V plough. The former breaks up the surface of the ground, and the latter following it pushes the displaced earth aside to make up a bank for the channel. With a pair of ploughs—one of each kind—2 miles of laterals can be made in one working day. The V plough as commonly used is of the simplest description, capable of being made on any farm, and modelled after the sketches given in Mr. Derry's Report to the Victorian Water Commission. One which I measured consisted essentially of two hardwood planks set on edge and bevelled off and bolted together at the apex, the one being 15 feet long and 9 inches by 5 inches in section, and the other 10 feet long and 15 inches by 2 inches in section. These two, besides being joined at the apex, were provided with a distance bar. The point of draught was on the longer timber, and the draught chain passed through a guide ring at the front of the plough. When at work, the longer beam follows the track of the ordinary plough and presses against the exposed face of the solid ground, the resistance of which enables the short side of the V to push out so much of the soil as has been already displaced.

In some cases, and particularly that of Mr. Hayes's property already referred to, the laterals have been made with considerable care, and with the intention of maintaining them permanently. In the Gunbower Station, where about 10 miles of main distributaries have been constructed, it is intended that the laterals should be regarded as purely temporary, and they will therefore be levelled and ploughed over if necessary or convenient at every change of crop. As the one important objection to the use of numerous laterals lies in the fact that they are serious obstacles to the effective use of agricultural machinery, this course decided on at the Gunbower Station must be looked on as a very interesting experiment. If successful—and there is little reason to doubt of its success—economy in water can be ensured by making laterals at short intervals, while the effective use of reaping machinery will not be interfered with, as the laterals can be levelled when the last watering is given to a crop.

The preservation of the slopes and banks of distributaries, by encouraging the growth of grasses on them, is one which has not been altogether overlooked in Victoria. On the Gunbower Station an experimental sowing of lucerne has been made on the banks of parts of the distributaries, and the result has been so satisfactory that the practice will be extended. The necessity for bearing in mind that the seeds of plants can be easily disseminated in the process of irrigation was strikingly exemplified on one property which I visited. In this case, Bathurst burrs were to be seen growing at intervals along the margin of the main distributary and the laterals, while no burrs were to be seen elsewhere in that neighbourhood. The manifest explanation of this was that the burrs had floated down the Murray and found their way into the pump well, from which they had been raised into the main distributary.

The chief benefit to be derived from a study of irrigation works in America and Victoria arises from the evidence they afford that by the adoption of machinery and of labour-saving appliances to the utmost extent possible, both in the construction of the works and in the subsequent agricultural operations, not only can irrigation works be made remunerative, but agriculture can be placed in a position to compete successfully with countries where an inferior class of labour is abundant and cheap. It would be difficult to overestimate the importance of the lessons thus taught by the irrigation works of America, and in a less degree by those of Victoria, and any incorrect inferences drawn from these works are therefore likely to be all the more mischievous. It will be on the whole a safe rule to assume that if we wish to know how to construct irrigation works cheaply, with such labour as we have available in New South Wales, excellent examples for our guidance are to be found in America,

and

and to some extent in Victoria; but if we require information as to the general alignment of canals, or the economical use of our water supply, or the principles of management and administration of irrigation works, we must look for guidance to the experience of India, Italy, Spain, and France.

As a general rule, the financial results of irrigation wherever practised in Victoria have been, so far, highly satisfactory. Among cereals, wheat is the crop most extensively irrigated, and the conclusion arrived at is, that with irrigation a good crop is a certainty, while, without irrigation, not only is a first-class crop rarely obtained but even a moderate crop can be had only in good seasons. Several of the wheat-growers in the Swan Hill Trust district informed me that as an average they could not depend on obtaining a crop of more than 10 bushels to an acre without watering, and that they could rely on having at least 20 bushels with watering. This statement does not agree with the figures for 1885 given in the Victorian Year Book, by Mr. Hayter, as the average produce of an acre of irrigated wheat is there given as only 10·64 bushels; but it has to be remembered that the compilation of statistics regarding irrigation has only commenced in Victoria, and that the returns did not take any account of what constituted "irrigation," so that land hastily and perhaps only partially flooded at a period too late to save the crop would be reckoned as irrigated. One thing is certain in this matter, namely, that if the farmers of the Gunbower district had obtained only 10·64 bushels of wheat per acre on an average from irrigated land, they would have been much less enthusiastic regarding the results of irrigation. The statistics of the past season, which are now being prepared, will no doubt throw much more light on the matter; but meanwhile it may be mentioned that the return for 1885 shows that, as compared with land not artificially watered, irrigated land gave twice the yield of oats and barley, about four times the yield of mangel-wurzel, more than three times the yield of hay, and about twice the yield of potatoes.

The question has been raised whether these Colonies can hope to compete in the production of cereals with other countries where labour is much less expensive. With reference to this, it should be remembered that no other portion of the population of a long settled country is so conservative as that engaged in agriculture. In India, which is rapidly approaching the first place as a wheat-exporting country, there has been, so far as can be ascertained, scarcely any improvement in agricultural appliances during the last 2,000 years. The immense increase in the export of wheat from that country is not in the slightest degree due to any improvement in the system of agriculture, but is the direct result of the construction of canals and railways by the Indian Government. In an elaborate report, prepared for the Government of the North-west Provinces and Oudh, on agriculture in the Cawnpore district, it is stated that in the case of a crop of wheat of about 16 bushels to an acre, twelve men will be required to reap 1 acre in a day, four oxen will take six days to tread out the grain, and four men will take a day to winnow it. When we compare this with the fact that a good reaper and binder, requiring only two men for its working, will reap 10 acres in a day of twelve hours, and that the appliances for the preparation of the ground are also immeasurably superior to those used in India, it is not difficult to understand how the higher cost of labour is compensated for by labour-saving appliances. The stripper, as well as the reaper and binder, is extensively employed in Victoria, and I was informed that the combined stripper and winnower is steadily coming into use. With one shift of three horses a stripper will reap the grain off from 8 to 10 acres in a day. As even the filling of the wheat into bags is done by a mechanical appliance, it may be reckoned that the produce of about 10 acres can be not only reaped but prepared for the market in one day by the combined use of a stripper, winnower, and bag-filler. Mr. John Garden, who has already been referred to in this report, and who has a holding of about 2,300 acres on the Barr Creek, at a distance of 18 miles from Kerang, afforded me some useful information on the subject of the labour required to manage irrigation. In reply to the question—"Supposing a man had 2,560 acres of land, 300 acres of which was under irrigated grain crops, 700 acres under irrigated grass, and the remaining 1,560 acres unirrigated, would that man, with the help of three others, manage his farm?" Mr. Garden said—"Certainly, if the three men assisting had an interest in the farm; as for instance, if they were sons of the owner. I should mention that this question was put after Mr. Garden had informed me of the labour employed by himself, the proportion being similar to that

in

in the case of his farm. In the latter, when the irrigation of 375 acres of wheat was in actual operation, the establishment employed consisted of two men to work the engine in turns, and a third to attend to the distribution of the water, that is three men altogether. During the same season, Mr. Garden irrigated about 750 acres of the native grasses, the total labour engaged in the farm being three men and one boy. So far as I could ascertain, this proportion of labour did not differ materially from that engaged on other properties where irrigation is used for similar crops. When mixed crops are grown more labour is required, and as an instance of this, Mr. Patchell, of Kerang, employs four men to attend to the management of 150 acres of such irrigation.

The relative suitability of different crops for irrigation is a subject which has received practical consideration on the Gunbower Station. The conclusion arrived at is that, under the circumstances there existing, the most advantageous crop to irrigate is lucerne, but it is intended to take one or two crops of wheat or oats off the land as it is broken up and to sow the lucerne afterwards. In the course of experiments with different crops the irrigation of prairie grass and also of cocksfoot grass was tried, but the result was not encouraging in either case, and the conclusion arrived at was that their comparative failure was due to the unsuitability of the climate. The irrigation of the native grasses also was tried on an extensive scale, as much as 2,000 acres having been flooded in one season on this station; but though the result was good, so far as increase of grass was concerned, the experiment was not deemed profitable. This conclusion is very different to that arrived at by Mr. Garden from his experience under circumstances differing but slightly from those at Gunbower. His opinion is decidedly in favour of the flooding of the native grasses. He states that the effect of a good flooding is not only very beneficial in the season during which it is given, but is also apparent in an increased growth of grass in the spring of the succeeding year. Mr. Garden also states that when he took up his selection the land would not keep one sheep to an acre, whereas now an acre of his irrigated grass land will maintain five sheep. Although, in addition to the crops mentioned, I found instances of the irrigation of maize, potatoes, fruit-trees, and vines, I did not hear of a single case in which artifical watering was considered to be otherwise than beneficial.

The cost of irrigation necessarily varies greatly, according to the distance of the source of the water supply, the height (if any) which the water has to be raised, the nature and configuration of the ground, the nature of the crop, and several other causes. Much can, however, be learned from the outlay incurred under known conditions, and from the rates which landowners have expressed their willingness to pay. In Mr. Garden's case, the cost of his engine and pump in position on the ground was £600, and his outlay in making about 7½ miles of channels amounted to about £100—that is a total capital expenditure of £700. This outlay has enabled him to irrigate from 350 to 400 acres of cereals, and about double that area of native grass. The gross expenditure was therefore equal to about 13s. for every acre irrigated; but as, roughly speaking, cereals and other crops would require twice as much water as grass land, the capital expenditure may be considered as equal to £1 per acre for land under crops and 10s. per acre for grass land. The combined cost of fuel for the engine and labour for working the engine and distributing the water is estimated by Mr. Garden to amount to only 1s. 6d. per acre on an average. The first successful application of the water was immediately followed by an increase in the value of the land, sufficient to considerably more than cover the capital outlay. In connection with the estimated cost of this irrigation, it has to be borne in mind that the lift is only about 5 feet on an average, and does not reach a maximum of more than 7 feet. In two other cases, in one of which the lift was only slightly greater than this, and in the other about double, the cost of irrigation, exclusive of interest on the plant, was estimated at 5s. per acre. In the Wimmera District the Water Works Trust has received several offers from landowners to pay from 15s. to £1 per acre per annum for sufficient water to irrigate crops.

The efficiency of the arrangements for the distribution of the water is a most important consideration when calculating the cost of irrigation. By raising a supply 6 feet from the River Loddon with an 8 horse-power engine and a 10-inch centrifugal pump, Mr. Patchell of Kerang irrigates 1 acre per hour, but has irrigated as much as 25 acres in a day. From his experience of the improvements which he has made

in

in the system of distribution, he estimates that the same plant would not irrigate more than 13 acres per day if it were in the hands of a person new to irrigation, and who had not provided a suitable arrangement of distribution channels. Mr. H. Hawkins, who irrigated about 500 acres of wheat in 1883 and the same area in 1884, by raising a supply of water with a 12-inch centrifugal pump from Kow Swamp, was able to flood from 15 to 20 acres in twenty-four hours. The lift in this case was about the same as that at Kerang.

The experience of Mr. Garden has been substantially confirmed by that of Mr. Yeo, of Kerang. The latter gentleman found that after placing his engine and pump in position and constructing distributaries, the cost of irrigating his land amounted to only 2s. per acre. This included the cost of working the engine and attending to the distribution of the water.

At a recent discussion in Melbourne on a paper read by Mr. G. Gordon on "Australian and American Irrigation," that gentleman supplied some valuable information regarding the cost of pumping. On the subject of irrigating by this means he states as follows:—"I made a very careful estimate of the cost of irrigating 500 acres of lucerne, allowing 2½ inches of water once a fortnight; the pump to be worked ten hours a day for 156 working days; the water to be raised 24 feet by a centrifugal pump at the rate of 300,000 gallons an hour, sufficient for 42 acres a day, and it amounted to £197 for the season, or about 8s. per acre. This is for pumping only. The same machinery applied to irrigating cereals would cost 2s. 8d. per acre, and would irrigate 400 acres.

"I have made some estimates for large and small quantities for different heights of lifting, and the result is shown in the following table:—

No.	Quantity in cubic feet per minute.	Height of Lift.	Cost of Pumping per 1,000 cubic feet.
1	33·7	100	1·5d.
2	635	24	0·32d.
3	2,222	39½	0·83d.
4	4,600	25	0·42d.
5	9,500	6	0·19d."

These rates show what a large margin exists between the cost of supplying water by pumping under fairly favourable circumstances and the price which landholders are willing to pay for the water. For instance, in the case of the 25-feet lift, with water supplied at the rate of 0·42d. for 1,000 cubic feet, the cost of the quantity required for the irrigation of 1 acre of wheat or other cereal would be only about 1s. 6d. This strikingly illustrates the advantages of irrigation, when it is considered that experienced farmers are willing to pay from 15s. to £1 per acre for a sufficient supply of water for the irrigation of such crops, and at a much higher rate for the irrigation of fruit-trees.

While the works which have been carried out in Victoria for water conservation and supply throughout the northern part of that Colony are a credit to the enterprise and skill which they illustrate, it could not be expected that in the short time which has elapsed since irrigation and water supply became a recognized national question, the whole ground of administration of the water supply of the Colony could have been dealt with. Further legislation is contemplated, and this will doubtless remedy the existing defects. It is not surprising that the constitution of two separate kinds of Water Trusts possessing different powers has given rise to some complications. The majority of the Trusts are termed "Waterworks Trusts," and were constituted under Act 716 of 1881; but recently "Irrigation Trusts" formed according to the provisions of Act 778 of 1883 have become more popular. For instance, at the time of my visit, an agitation was being carried on for the formation of an Irrigation Trust at Cohuna, within the district of the Swan Hill Waterworks Trust, and the agitators seemed confident of success. The Swan Hill Trust had, however, passed a resolution protesting against the transfer of the creeks, and particularly the Barr Creek, to the jurisdiction of the proposed Cohuna Irrigation Trust. So far as I could ascertain, the chief grounds on which some of the former object to the Waterworks Trusts are—(1) that they deal only with the supply of water for domestic use and for stock, and (2) that the members of the Trusts are elected by the Shire Councils, and not by the persons who are interested in irrigation. The first objection appears

in

in the main correct, though it is the intention of the Waterworks Trust to allow irrigation to be carried on from their works whenever water can be spared for that purpose. The second objection is a very important one, as it is alleged that under existing circumstances it is possible to have members of Waterworks Trust who take no interest in irrigation, or who are even opposed to it. Another point in connection with the legislation which has not yet been dealt with, is the propriety of defining the right of the State to the rivers and lakes. The following case which arose last year is very suggestive on this subject:—A farmer, who had expended £600 in providing himself with an engine and a centrifugal pump, and who had irrigated 500 acres by pumping from Kow Swamp in two successive years, was served with a summons for illegally using a supply of water belonging to the Swan Hill Trust. The farmer was fined, but the amount of the fine was subsequently remitted by order of the Government. It is safe to infer that, when this man purchased his plant, he believed that his riparian rights entitled him to pump from this swamp; and the undisturbed use of the water for two consecutive seasons could not fail to confirm him in this opinion. Nor would a study of the powers of Trusts, as set forth in Act 716 of 1881, throw much light on the extent to which that law sets aside the British law of riparian rights. The occurrence of cases like these, besides showing that the legislative problems connected with water conservation in Victoria are not all solved, is also instructive to this Colony in exemplifying the nature of the questions which are likely to arise.

In addition to inspecting the works for irrigation in the Gunbower District, and making myself acquainted with the details of the arrangements being carried out by the Waterworks Trusts, I availed myself of the opportunity of visiting the works for the mitigation of the dangers arising at Melbourne from floods in the Yarra, and also of inspecting the works for the water supply at Ballarat.

With regard to the former works, so long ago as February, 1879, the opinion was given by Sir John Coode "that perfect immunity from floods can only be secured by removing the rock obstructions in the bed of the Yarra from just above Prince's Bridge to below Falls Bridge." The dangers of delay in the removal of the Falls Reef was the subject of an important memorandum by Mr. W. H. Steel, the Inspector-General of Public Works, in 1883. Since then the removal of the reef has been put in hand and is now in active progress. Ford's Rock Drills are used for making the blast-holes, which are at regular intervals, and are all carried to 16 feet below low-water. The explosive used is dynamite, in charges varying up to 10 lbs., and the blasts are fired in groups by an electric battery. The débris is lifted into barges by a spoon dredge. Up till February of the present year 33,000 cubic yards had been removed in this manner.

The Ballarat Waterworks have played a similar part in connection with the prosperity of that town and the development of mining enterprise in its vicinity to that of the Coliban Works in the case of Castlemaine and Sandhurst. It is unnecessary here to describe the Ballarat Works in detail, as they are very similar in their general character to the works for the supply of Melbourne. The expenditure on them has been £275,000, and the Ballarat Water Commissioners pay to the Government 4½ per cent. on that amount. The quantity of water now generally used in summer is 3½ million gallons per day, and this includes the supply used for mining, manufactures, and water-power. In winter the required quantity falls to about 3 million gallons per day. When the mining industry was more prosperous the quantity used went as high as 4½ million gallons per day, and this taxed the available supply to the utmost, as the catchment area from which it is derived is only about 7,600 acres in extent. The following are the rates charged for water:—

(*a*) For domestic use in houses valued at £20 per annum or less	£1 per annum.
(*b*) For houses valued at over £20 per annum	5 per cent. on assessment.
(*c*) For manufactures	1s. per 1,000 gallons.
(*d*) For steam-boilers	" " "
(*e*) For crushing purposes	3d. per 1,000 gallons.
(*f*) For motive power	" " "

The working expenses amount to about £4,000 per annum.

The greatest pressure at any part of the mains is 134½ lbs. per square inch or 310 feet of head. The pressure gauge in the office of the Inspector shows about 112 or 113 lbs. per square inch.

While the works are, as a rule, of well-known types, the flume shown in the accompanying plan presents some unusual features. This work consists of a trapezoidal flume of sheet iron of No. 12 gauge, that is of a thickness of less than one-ninth of an inch, supported in a framework of timber. It has been seven years in use, and has given entire satisfaction. It is laid with a fall of 8 feet per mile, or 1 in 660; its length is 920 feet, and its total cost was £1,500. The ironwork is cleaned annually, and coated with a mixture prepared in the proportion of 2 lbs. of tallow and 2 lbs. of resin to 1 gallon of tar. This is put on in hot weather, and at a time when the channel is not in use. It is found that the mixture applied assumes a glassy surface, and does not affect the taste of the water. The erection of this flume was simply and expeditiously done by making it in sections above its bed, lowering the sections by screws, and riveting them together in position.

The Ballarat Water Commission owns 2,300 acres of land outside the limits of the catchment area of the present works. This land is now worth £30 per acre on an average, and the Commissioners have recently let 800 acres at £1 per acre per annum.

It should be mentioned that Mr. C. H. O. Bagge, C.E., was the Engineer who had charge of the design and construction of the Ballarat Waterworks, and that the details regarding them were furnished to me by Mr. J. Cameron, Foreman of Works, who now holds charge of them on behalf of the Commissioners.

For details regarding the Victorian Works mentioned, I am indebted chiefly to the painstaking kindness of the gentlemen referred to in connection with them; but I am also under obligations for valuable assistance to many others, and prominent among them, to Mr. Conant, Mayor of Echuca, Mr. John Tracy, Works Manager on the Gunbower Station, and Mr. Kempson, Engineer to the Swan Hill Waterworks Trust.

H. G. McKINNEY, M.E., M.I.C.E.,
Engineer to the Commission.

24th April, 1886.

APPENDICES TO SECOND REPORT.

APPENDIX II.

MELBOURNE WATER SUPPLY.

Water Supply Office,
Melbourne, December, 1885.

SPECIFICATION for the manufacture and supply of Wrought-iron Water Pipes for the use of the Melbourne Water Supply Branch of the Public Works Department.

The whole of the workmanship required in the construction of the pipes the subject of this contract shall be performed within the Colony of Victoria, but the materials of which such pipes shall be constructed, as wrought-iron plates and rivets, may be imported.

The contract shall include the providing of all materials as hereinafter described, and labour for the manufacture, coating, testing, weighing, and delivery of thirty-four thousand three hundred (34,300) feet run, more or less, of wrought-iron pipes of thirty (30) inches diameter, and weighing approximately 1,430 tons, together with all tools, fittings, templets, patterns, premises, and every and all of the appliances necessary for its due fulfilment in accordance with this specification and accompanying drawing.

The materials used in the contract shall be the best of their respective kinds.

The wrought-iron plates shall be of the best brand of Staffordshire, or other brand of equal quality in the opinion of the Chief Engineer, and on each plate the brand must be clearly discernible, and the iron in the plates shall, under such tests as may be ordered by the Chief Engineer, be capable of withstanding a tensile strain of not less than twenty tons per square inch of original section, with an extension of not less than 8 per cent. of the tested length.

The rolled plates for faucets shall be of such a quality that they will withstand a tensile strain of not less than 23 tons per square inch of original section, with an extension of not less than 15 per cent. of the tested length.

The rivets shall be made from the best Lowmoor iron, or of colonial scrap iron, and shall be capable of carrying not less than 26 tons per square inch of original section, with an extension of not less than 18 per cent. of the tested length.

The above tests for plates and rivet-iron are to be made on carefully prepared pieces of the full diameter of the rivets, and for plates they shall have a sectional area of not less than ·75 of a square inch, and they shall have a length in any case of not less than eight inches between the shoulders; all to be cut and tested the length way of the grain. The Contractor shall cut and test pieces from any plate or bar the Chief Engineer or Superintending Officer may indicate; one plate in each fifty being tested if required by the Superintending Officer; and in the event of the selected plate not standing the test, the whole fifty may be rejected.

The Contractor shall provide all suitable appliances, labour, and material for carrying out the tests, and shall prepare the test pieces, and load them to their breaking points whenever required to do so by the Superintending Officer.

The pipes are to be constructed of plates, as described, one quarter ($\frac{1}{4}$) of an inch thick, bent end-on with lap joints longitudinally and transversely, as shown on drawings.

The plates must be of such length as to be equal to the whole circumference of the pipe, together with provision for lap in one piece or plate. The width of the plate shown on the drawing is four (4) feet, but the Contractor will not be restricted to such width if he will substitute therefor plates of greater width; but plates of lesser width than four (4) feet will not be accepted. The lap on the longitudinal joints shall be $2\frac{1}{2}$ inches, the joints to be double riveted with rivets, as described, of half an inch ($\frac{1}{2}$) diameter, pitch one and a half ($1\frac{1}{2}$) inches.

The lap for the transverse seam shall be one and a half ($1\frac{1}{2}$) inches, single riveted with $\frac{1}{2}$-inch rivets, $1\frac{1}{2}$-inch pitch, as described for the longitudinal joints.

The plates are to be riveted up so as to form pipes of about 31 feet in length. Each length of pipe is to be fitted with a socket of rolled iron $\frac{3}{8}$ of an inch in thickness with bead, and of the section shown on drawing, welded into a ring and firmly and tightly riveted to the pipe, so as to resist hydraulic pressure as hereinafter described, by rivets $\frac{5}{8}$ inch diameter and $1\frac{3}{4}$-inch pitch.

The faucet in every case to be riveted on a segment of the pipe of the greater of the two diameters of which the pipe shall be formed, and such rivets in the pipe as shall be found necessary shall be countersunk under the faucet ring.

The rivets in one foot in length of the spigot end of the pipe to be countersunk, to allow of its insertion in the socket of the adjacent pipe.

All seams and joints and rivets shall receive such amount of caulking as shall render them watertight under the test pressure hereinafter to be described.

The pipes shall be perfectly straight longitudinally, and each segment of a pipe shall be perfectly cylindrical, as also shall the socket on each pipe.

Each pipe to be fitted with two lugs as shown, for the purpose of suspension, to be of the dimensions given on drawing, and to be secured to the pipe near the spigot end with two $\frac{1}{2}$-inch rivets in each lug.

The rivet-holes in plates and sockets may be punched, in which case multiple punches shall be used. The holes are to be of the size specified for rivets; they shall be exactly spaced, and shall come into position accurately for receiving the rivets with the least amount of rimering; drifting will on no account be allowed in any part of the work. The punching shall be so performed that the smaller ends of the holes shall come together and the larger ends against the rivet heads, and all burrs resulting from punching shall be removed.

The sizes given for the rivets are the sizes of the rivets when closed in the holes. The rivets must in no case, when cold and before being riveted up, be less than $\frac{1}{32}$ of the diameter of the holes. Any hole through which the rivet will not readily pass must be rimered out until a mandrel of the exact diameter specified for the rivet holes will pass through. The rivets shall be long enough and of a suitable form for making good snap heads inside and out.

All riveting, excepting such as must be countersunk under joints of sockets, shall be executed with hydraulic riveting machines of approved pattern.

Each length of pipe shall be tested by hydrostatic pressure equal to a column of water 350 feet in height, and all leakages developed at such or any less pressure shall be made good and watertight by caulking to the satisfaction of the Superintending Officer.

In

In the event of the fracture of a plate, or a rupture of a joint, the pipe in which such fracture or rupture occurs shall be destroyed in the presence of an inspector. The pipes shall be tested either before or after the coating process shall have taken place, as shall be determined from time to time by the Superintending Officer.

All the pipes are to be coated with a composition of refined Trinidad asphaltum and coal tar, in the proportions of 60 per cent. of refined asphaltum and 40 per cent. of tar.

Each pipe before being coated shall be thoroughly dried by being heated above atmospheric temperature, so that when immersed in the coating material the skin of the iron shall be perfectly dry, to secure the perfect adhesion of the coating material; and no pipe shall be permitted to be immersed in the coating bath unless it be so thoroughly dried.

Prior to being mixed with the asphaltum, the tar must be heated to 400 deg. F. and maintained at such temperature so long as shall be necessary, in the opinion of the Superintending Officer, for the release of all obnoxious oils.

The asphaltum and tar, after the latter shall have been heated as described, shall be melted together in a tank or cauldron and run into a bath of suitable size, the amalgamated material to be maintained continuously while coating shall be in progress at a temperature of 300 deg. F.

Each pipe after being heated and dried as described, and before it shall have had time to cool, shall be immersed in such bath so as to be completely submerged, and after remaining therein not less than twenty minutes shall be lifted and suspended by the lugs, socket down, in a vertical position, to allow of dripping. When the coating material shall have sufficiently set, the pipe shall be again submerged in the bath and at once withdrawn, and suspended as before described until the coating shall have partially set. The pipe then to be lowered on to a bed of clean sand, and rolled until the particles of the latter shall have become incorporated with the coating to such degree as shall be directed by the Superintending Officer.

Each length of pipe shall be weighed in the presence of an officer of the Melbourne Water Supply Branch, and payments will be made on the weights so obtained and recorded.

Delivery of the pipes will be taken at the works of the Contractor, if such works be situated within three (3) miles of the Melbourne General Post Office, and if such works be at a greater distance than three (3) miles from such point, delivery must be made by the Contractor at the Tank Premises, Eastern Hill, or at Raleigh's Yard, Queen's Wharf, as shall be directed.

Tenderers shall state the price per ton at which the pipes herein described will be manufactured and delivered in accordance with this Specification; they shall also state the least weight or quantity they will guarantee to deliver per month, the time in which the first delivery will be made, and also a statement of the time required to complete and deliver the entire contract quantity, such time to commence from the date of acceptance of tender and to form a condition of the contract.

APPENDIX III.

[*From the "Victoria Government Gazette" of 3rd August, 1883. No. 76.*]

CASTLEMAINE AND SANDHURST WATER SUPPLY DISTRICT.

RULES AND REGULATIONS.

THE Governor in Council, in pursuance of and in exercise of the powers and authorities conferred by *The Water Works Act* 1865, has made the Rules, Regulations, and Orders following, respecting the Castlemaine and Sandhurst District Water Supply, being a work constructed under the authority of the said Act:—

1. The district which shall be rated for the Castlemaine and Sandhurst District Water Supply shall be the whole of the borough of Castlemaine, the whole of the borough of Chewton, the whole of the united shire of Mount Alexander, the whole of the united shire of Metcalfe, the whole of the city of Sandhurst, the whole of the borough of Eaglehawk, the whole of the shire of Marong, the whole of the shire of Huntley, the whole of the shire of Strathfieldsaye, and that portion of the shire of Maldon comprised in the extension to Winter's Flat.

2. The following rates and charges are those which the owners and occupiers of lands and tenements shall pay in respect of water supplied by the Board within the said district, that is to say:—

(1.) On every house or tenement of £20 annual value and under, One pound per annum.

(2.) On every house or tenement above the annual value of £20, a rate of Five pounds per centum on the amount of the valuation up to £300 inclusive; Three pounds per centum on the amount of the valuation in excess of £300 up to £700; and Two pounds five shillings per centum on the amount of the valuation in excess of £700.

(3.) On every shop, not used as a domicile, above the annual value of £20, a rate of Four pounds per centum on the amount of the valuation up to £300 inclusive; Two pounds per centum on the amount of the valuation in excess of £300 up to £700; and One pound five shillings per centum on the amount of the valuation in excess of £700.

(4.) The rates to be charged for water supplied from stand-pipes shall be One shilling per 100 gallons.

(5.) The rates to be charged for water supplied by the Board from the mains by measure shall be One shilling per 1,000 gallons, except in the cases hereinafter specially mentioned.

(6.) For water supplied from the mains for sluicing purposes, the rate shall be Twopence per 1,000 gallons.

(7.) For water supplied from the main for mining purpose other than sluicing, the rates shall be Fourpence per 1,000 gallons.

(8.) For water supplied from the channels to crushing-mills, pyrites-works, &c., the rate shall be Threepence per 1,000 gallons.

(9.) For water supplied to gardens and nurseries, cultivated for trade purposes, and to cricket-grounds, the rate shall be Sixpence per 1,000 gallons.

(10.) For water supplied to any cemetery, the rate shall be Fourpence per 1,000 gallons.

(11.)

(11.) For water supplied to any public parks or gardens, the rates shall be Sixpence per 1,000 gallons.

(12.) *a.* The rate to be charged for water supplied from the main aqueducts and from any of the branch aqueducts which diverge therefrom shall be One halfpenny per 1,000 gallons, in quantities of not less than one million gallons per month.

b. The rate to be charged for water supplied in fixed quantities of less than one million gallons from any portion of the main aqueduct, or from any of the branch aqueducts, shall be for quantities—

Under 250,000 gallons ... ... 2d. per 1,000 gallons.
Above 250,000 gallons but under 500,000 gallons—
The first 250,000 gallons ... ... 2d. per 1,000 gallons.
For the excess ... ... 1d. „ „
Above 500,000 gallons but under 1,000,000 gallons—
The first 500,000 gallons ... ... 1½d. per 1,000 gallons.
For the excess ... ... ½d. „ „

Delivery of the water shall be taken within one month from the time of purchase, failing which, the purchaser shall forfeit all his right thereto.

3. The minimum quantity of water to be charged for in each case where water is supplied by measure shall be—

(1.) If for domestic and other than domestic purposes, the quantity of which, the charge at 1s. per 1,000 gallons, would be equal to the amount of the assessed rate which would be payable for the premises so supplied, if supplied otherwise than by measure; and

(2.) If for other than domestic purposes only, 25,000 gallons per quarter.

4. A supply of water for domestic purposes shall not include a supply of water to any livery or carrier's stables, or a supply for any manufacturing purposes, or for irrigation (which shall mean any mechanical or artificial contrivance for conveying water to the roots of plants without labour), or for water-power, or for fountains, or for any ornamental purpose. No hose or pipe is to be applied to any pipes or taps for the purpose of watering the ground, or trees or plants, or washing the house walls, or a carriage, or for any similar purpose, unless the water is charged for by meter. Syphon pumps will not be allowed unless the water is supplied by measure.

5. Any person receiving water from the Board who shall take and carry away such water from his premises, or who shall allow any person to take or carry away such water, or shall sell the same to any other person, shall be liable to a penalty not exceeding Five pounds.

6. Any person not having agreed to be supplied by the Board who shall take or carry away water from any drinking tap, trough, or private or public service-pipe, shall be liable to a penalty not exceeding Five pounds.

7. Before any person shall affix any service-pipe to any pipe of the Board, or alter, repair, or in any manner interfere with any pipe of the Board, or any service-pipe, cock, or fitting connected with the pipes of the Board, he shall obtain from the Board a license in that behalf to execute such works; and any unlicensed person affixing, altering, repairing, or in any manner interfering with any such pipe, service-pipe, cock, or fitting as aforesaid, shall be liable to a penalty not exceeding Ten pounds.

8. Before any such license shall be granted by the Board, the person applying for same shall satisfy the Board that he is a competent plumber.

9. Any person, whether licensed as aforesaid or not, who shall offend by opening any ground so as to uncover any pipe or pipes, the property of the Board, without giving two days' notice to the Board of his intention so to do, or who shall in any way tamper with or alter any pipe the property of the Board, without the permission in writing of the Board being first obtained, or who shall wilfully or carelessly break, injure, or open any lock, cock, valve, pipe, work, or engine, the property of the Board, shall be liable for each such offence to a penalty not exceeding Twenty pounds.

10. Any person, whether licensed as aforesaid or not, who shall lay any pipe, to communicate with the pipes of the Board, without giving two days' notice of the day and hour when such pipe is intended to be made to communicate with the pipes of the Board, or who shall make such communication except under the superintendence and according to the directions of some officer of the Board, or who shall lay any leaden or other pipe to communicate with the pipe of the Board, of a strength and material not sanctioned by the Board, shall be liable for each such offence to a penalty not exceeding Five pounds; and in the event of continuing the offence, to a further penalty of Two pounds for each day after notice of the offence from the Board. Wrought-iron piping, of approved quality, and lead piping of the following weights only, will be allowed to be fixed for either internal or external service :—

Diameter of pipe.	Weight of pipe per yard.
⅜ inch	5 lbs.
½ „	6 „
¾ „	7½ „
¾ „	9 „
1 „	12 „
1¼ „	16 „
1½ „	20 „

No service of a larger bore than ½-inch will be permitted, unless by special consent of the Board.

11. If any person shall neglect to repair any service-pipe conveying water from the pipes of the Board into the premises of such person, after having received notice from any officer of the Board that such service-pipe requires repairing, the Board may stop the water from flowing into such premises, either by cutting off the service-pipe or otherwise as to the said Board may seem fit, until the necessary repairs shall have been effected. The service-pipes from the main being the property of the owners or occupiers of the tenements supplied by such service-pipes, the occupier (if any), and if none, the owner, shall in every instance in which any damage shall be caused by reason of such service-pipe being leaky, or otherwise out of repair or broken, be liable to a penalty not exceeding five pounds; and in the event of continuing the offence, to a further penalty of two pounds for each day after notice of the offence from the Board.

12. Any person supplied with water by the Board who shall wilfully or negligently allow the same to run to waste shall be liable for each offence to a penalty not exceeding Five pounds; and in the event of continuing the offence, to a further penalty of Two pounds for each day after notice of the offence from the Board.

13. If any meter should cease registering, and, during the time it is undergoing repairs, the Board shall estimate and charge for the water consumed by taking an average of the quantity used during the previous quarter, or during the corresponding period of the preceding year.

14. Any person, whether licensed as aforesaid or not, connecting any service-pipe or branch service-pipe with any steam-boiler for the purpose of feeding or supplying the same with water, without first affixing a self-acting valve for preventing the pressure of the steam reversing or affecting the dial of the meter, shall be liable to a penalty not exceeding Five pounds; and in the event of continuing the offence, to a further penalty of Two pounds for each day after notice of the offence from the Board.

15. No meter shall be affixed unless the dial of the same is capable of registering one million (1,000,000) gallons.

16. Over-flow pipes to private baths will not be permitted.

17. Water-closets will not be allowed to be supplied direct from the main, but from a cistern only, so constructed that the water cannot flow continuously, and that not more than two gallons can escape at each flush.

18. If any person supplied with water by the Board does or causes to be done anything in contravention of any of these Regulations, or fails to pay his rates when due, or fails to do anything which under any of these Regulations ought not to be done, or wilfully or negligently allows water to run to waste, the Board may cut off the supply of water from the premises of such person, either by cutting the pipes by or through which water is supplied or otherwise, and may cease to supply him with water so long as the cause of injury remains or is not remedied.

19. The streets shall not be watered from hydrants or fire-plugs by means of a hose, but the water is to be applied to the streets by carts or by manual labour, or by special stand-pipes of approved size and form.

20. The water supplied in the above-named district shall be received and consumed under and in accordance with these Regulations, and not otherwise, through pipes and meters laid, placed, and being under and in accordance with the same Regulations, and not otherwise.

21. In the construction of these Rules and Regulations the word "person" shall be deemed to extend to and include a Corporation whether aggregate or sole, and the word "Board" shall mean the Board of Land and Works.

22. The Rules, Regulations, and Orders affecting the Castlemaine and Sandhurst District Water Supply, made on the 7th January, 1878, the 4th February, 1878, the 4th March, 1878, the 12th August, 1878, the 28th October, 1878, the 4th March, 1879, the 28th February, 1881, and the 26th September, 1882, respectively, are hereby repealed.

ALFRED DEAKIN,
Minister of Water Supply.

Office of Mines and Water Supply, Melbourne.

Approved by the Governor in Council, the 16th July, 1883.
ROB. WADSWORTH, Clerk of the Executive Council.

NEW SOUTH WALES.

COUNTRY TOWNS WATER AND SEWERAGE ACT.

(BOROUGH OF NEWCASTLE—BY-LAWS.)

Presented to Parliament, pursuant to Act 44 Vic. No. 14, sec. 13.

Colonial Secretary's Office,
Sydney, 12th March, 1886.

BOROUGH OF NEWCASTLE.—BY-LAWS.

THE following By-laws, made by the Council of the Borough of Newcastle, under the "Country Towns Water and Sewerage Act," 44 Victoria No. 14, for regulating the supply of water in that Municipality, having been confirmed by His Excellency the Governor, with the advice of the Executive Council, are published in accordance with the requirements of the above-cited Act.

GEORGE R. DIBBS.

BY-LAWS to enable the Council of the Borough of Newcastle to establish a rate for water supply purposes, and for fixing the scale of charges for water supplied by meter, under the powers conferred by the "Country Towns Water and Sewerage Act," 44 Victoria No. 14.

The Council of the Borough of Newcastle doth hereby, pursuant to and in exercise and execution of the powers and authorities conferred by the Country Towns Water and Sewerage Act of 1880, make the following rate, to take effect from the first day of January and the first day of July in each year, upon all lands and tenements within the area of any Water District within which water is authorized to be supplied.

1. The rates and charges hereinafter specified are those which the owners and occupiers of lands and tenements shall pay in respect of water supplied otherwise than by meter for domestic purposes.

2. On every house, tenement, or land there shall be paid to the Council the annual minimum sum of ten shillings, and in no case shall water be supplied at less than that sum.

3. On every house or tenement there shall be paid the rate of five shillings per room for each and every room in such tenement, all out-houses to be excluded, except bath-houses.

4. The charge for water supplied by meter for steam boiler purposes shall be at the rate of two shillings per thousand gallons; the minimum quantity to be charged for water supplied to any such boiler shall be ten thousand gallons per month.

5. The charge for water supplied by meter for manufacturing and other purposes, unless otherwise specified, shall be at the rate of two shillings per thousand gallons; the minimum quantity to be charged for water supplied shall be ten thousand gallons per month.

6. The charge for water supplied by meter to ships and vessels in the Port shall be at the rate of four shillings per thousand gallons, and each party taking water for use of ships, &c., shall provide their own meter.

7. The charge for water supplied by meter to charitable institutions for all domestic purposes shall be at the rate of sixpence per thousand gallons.

8. The charge for water supplied by meter to cricket and bowling clubs shall be at the rate of one shilling per thousand gallons.

9. The charge for water supplied by meter for irrigation, gardens, nurseries, and private fountains shall be at the rate of one shilling and sixpence per thousand gallons.

10. The charge for a temporary supply of water during the erection of new buildings shall be ten shillings per centum on the amount of contract for stonework, brickwork, and plastering, or the Council may require a meter to be fixed, and the charge shall be one shilling and sixpence per thousand gallons.

11. The charge for warehouses and wholesale stores, not being domiciles, shall be four shillings per thousand gallons; the minimum quantity to be charged for water supplied shall be two thousand gallons per month.

12. The charge for water supplied for motive power, public baths, and troughs in streets shall be at the rate of sixpence per thousand gallons.

13. All accounts for water supplied under special agreement or by meter shall be paid monthly.

Made and passed by the Council of the Borough of Newcastle, this twenty-eighth day of December, in the year of our Lord one thousand eight hundred and eighty-five.

(L.S.) C. W. MORGAN,
Mayor.

EDWARD S. HOLLAND,
Town Clerk.

1885–6.

NEW SOUTH WALES.

COUNTRY TOWNS WATER AND SEWERAGE ACT OF 1880.

(MUNICIPAL DISTRICT OF DENILIQUIN—BY-LAWS.)

Presented to Parliament, pursuant to Act 44 Vic. No. 14, sec. 13.

Colonial Secretary's Office,
Sydney, 22nd February, 1886.

MUNICIPAL DISTRICT OF DENILIQUIN.—BY-LAWS.

THE following By-laws relating to the management and regulation of Water Supply, made by the Council of the Municipal District of Deniliquin, under the power conferred by the "Country Towns Water and Sewerage Act of 1880," having been confirmed by His Excellency the Governor, with the advice of the Executive Council, are published in accordance with the requirements of the above-cited Act.

JOHN ROBERTSON.

MUNICIPAL DISTRICT OF DENILIQUIN.

BY-LAWS FOR THE MANAGEMENT AND REGULATION OF WATER SUPPLY.

The Mayor and Aldermen of the Municipal District of Deniliquin, pursuant to and in exercise and execution of the powers and authorities conferred on such Council by the "Country Towns Water and Sewerage Act of 1880," make the following By-laws:—

Previous By-laws repealed.

1. That all existing By-laws and Regulations in connection with water supplied from the Council's works be and the same are hereby repealed, except as to anything already done or committed, or the recovery of any rates or charges due and payable thereunder.

Rates and charges.

2. The following rates and charges are those which the owners and occupiers of lands and tenements shall pay in respect of water supplied by the Council, that is to say,—

(a) On every house or tenement of £25 assessed annual value and under, if not supplied by meter or special agreement, twenty-five shillings per annum.

(b) On every house or tenement above the annual value of £25, if not supplied by meter or special agreement, a rate of one shilling for each pound sterling on the amount of the assessed Municipal valuation up to £200 inclusive, and three pounds (£3) per centum on the amount of assessed valuation on all the amounts in excess of £200.

(c) Livery and coach-horse stables and hotel premises where horses are generally kept, to be supplied by meter.

(d) Water supplied for irrigation of gardens, ornamental grounds, manufactories, or otherwise, when more than ordinary consumption is required, shall be by meter.

(e) Tenements built and used for storage purposes only above £50 annual value, and not having supply or stand-pipes laid on, shall be subject to a rate of £2 10s. per centum per annum on assessed valuation.

(f) Public horse troughs 10s. per annum, steam boilers 10s. per annum for each horse-power of such steam boiler; water carts from stand-pipes 6d. per load of 50 gallons or less.

(g) Unimproved town allotments and suburban lands if not distant more than 150 feet from any main or pipe of the Council's, shall be charged a minimum rate of 2s. 6d. per allotment up to £50 assessed capital value, all in excess of this 5 per centum on assessment.

(h) Water supplied to hospitals or other charitable institutions shall be by special agreement.

(i) For water supplied temporarily to buildings in course of progress 20s. per centum on the amount of the contract for stonework, brickwork, and plastering, or the Council may require a meter to be fixed, the charge to be the ordinary one in use for water supplied by measure or by agreement.

(j) Water required for market gardens or for purely agricultural purposes may be supplied by measurement at such times and at such charges as the Council may agree to.

(k) For water supplied by the Council by measurement the charge will be (except in cases referred to in preceding section) at the rate of one shilling and sixpence per one thousand gallons.

(l) The minimum quantity of water to be charged for in each case where water is supplied by measure (except by agreement) shall be equal to what would have been charged for the premises so supplied is supplied otherwise than by measure, but in no case shall less than 25,000 gallons per quarter be charged for.

The foregoing to be subject to section 13 of the "Country Towns Water and Sewerage Act of 1880."

These By-laws were made and passed by the Municipal Council of Deniliquin, and the seal of the said Council was hereunto affixed the twenty-first day of December, one thousand eight hundred and eighty-five.

(L.S.) ALFRED JAMESON,
Mayor.

GEORGE MINTO,
Council Clerk.

1885-6.

NEW SOUTH WALES.

COUNTRY TOWNS WATER AND SEWERAGE ACT.

(NOTIFICATION OF CONSTRUCTION OF WORKS FOR WATER SUPPLY FOR BOURKE.)

Presented to Parliament, pursuant to Act 44 Vic. No. 14.

Department of Public Works, Sydney, 18th August, 1886.

NOTICE is hereby given that His Excellency the Governor, with the advice of the Executive Council, has been pleased, under the powers conferred upon him in that behalf by the 124th section of the Country Towns Water and Sewerage Act of 1880, 44 Vic. No. 14, to authorize the construction, under the direction of the Minister of Public Works, of the necessary works for water supply for the Town of Bourke, at the request, and pursuant to the resolution of, the Municipal Council of the said Town, copy of which Resolution is appended hereto for general information.

Dated in Sydney, this 18th day of August, 1886.

WILLIAM JOHN LYNE,
Minister for Public Works.

Copy of Resolution submitted to and passed by the Council of the Municipal District of Bourke, at a meeting of the Council thereof, held on the 28th day of June, A.D. 1886 :—

Present: His Worship the Mayor (in the Chair), and Aldermen Biddulph, Donohoe, Huggins, Bloxham, Daniell, Colless, and Gray.

Moved by Alderman Huggins, seconded by Alderman Gray, and carried unanimously :—"That the Council of the Municipality of Bourke having taken into consideration the question of water supply for the Town of Bourke, do hereby request His Excellency the Governor, with the advice of the Executive Council, to take all such steps and cause such works to be executed as may be necessary to provide a water supply for the Town of Bourke, and the said Council, on behalf of the Municipality of Bourke, hereby agree to do and undertake all liabilities and obligations mentioned in section 125 of the Act 44 Vic. No. 14, and it is hereby expressly agreed that such liability is accepted for the total amount to be expended on such works, whatever such amount may be."

J. T. READFORD,
Mayor.

[3d.] 1022—

1885–6.

NEW SOUTH WALES.

WATER SUPPLY, TOWN OF WENTWORTH.

(NOTIFICATION.)

Presented to Parliament, pursuant to Act 44 Vic. No. 14.

Department of Public Works, Sydney, 22nd October, 1885.

NOTICE is hereby given that His Excellency the Governor, with the advice of the Executive Council, has been pleased, under the powers conferred upon him in that behalf by the 124th section of the Country Towns Water and Sewerage Act of 1880, 44 Vic. No. 14, to authorize the construction, under the direction of the Minister of Public Works, of the necessary works for Water Supply for the town of Wentworth, at the request, and pursuant to the resolution of, the Municipal Council of the said town,—copy of which resolution is appended hereto for general information.—Dated at Sydney, this 22nd day of October, 1885.

JOHN RAE,
Under Secretary for Works.

COPY of a resolution submitted to and passed by the Council of the Municipality of Wentworth, at the regular meeting of the Council, held on the (10th) tenth day of February, 1885:—

"That the Council of the Municipality of Wentworth having taken into consideration the question of a Water Supply for the town of Wentworth, do hereby respectfully request that His Excellency the Governor, with the advice of the Executive Council, will be pleased to take such steps and cause all such works to be executed as may be necessary to provide a Water Supply for the said town of Wentworth, and the said Council on behalf of the Municipality of Wentworth, do hereby agree to undertake all the liabilities and obligations mentioned in section 125 of the Act 44 Victoria No. 14, and it is hereby expressly agreed that such liability is accepted by the said Council for the total amount expended on such works, whatever that amount may be."

W. J. HOLDING,
Mayor.

Council Chambers, Wentworth, 11th February, 1885.

1885–6.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

SYDNEY WATER SUPPLY.

(REPORT OF SIR JOHN FOWLER ON PROSPECT DAM.)

Ordered by the Legislative Assembly to be printed, 7 April, 1886.

Sir John Fowler to The Minister for Works.

Sir, Sydney, 23 March, 1886.

I have the honor to acknowledge your request that I should examine the works of the Prospect Dam, now in course of construction.

The object of my examination, as you explained to me personally, was solely with reference to the stability of the dam and the works immediately connected therewith, and not with reference to the merits of the whole scheme as a Water Supply to Sydney, either as regards itself, or in comparison with any other scheme.

Under these circumstances, I do not consider it necessary to make you a detailed report on the subject.

Before proceeding to the site of the dam I thought it proper to examine, at Mr. Moriarty's office, not only the detailed drawings of the dam itself, but also those of the works for admitting the water into the dam, and those for drawing off the water by the watercourse to Sydney, by the waste weir, and by the pipes for emptying the reservoir, all works of the hightest importance, and intimately connected with the efficiency and safety of the dam.

I also checked the various hydraulic calculations, and made my own, so far as appeared to me to be necessary for the objects of my report; and I also availed myself of the valuable information on rainfall obtained by Mr. Russell, the Government Astronomer.

I was anxious to investigate these questions, from the fact, which is well known to you and to every one in the Colony, that the periods of rainfall and drought, and the quantity of rain at various times, are more irregular than in England, and therefore the provisions for adequate storage, overflows, &c., must be far greater.

The important duty of examining the character and quality of the work on the spot was my next step.

Fortunately the present condition of the works is peculiarly favourable for this practical examination, as every part and description of work is in progress, and open to view.

I was accompanied over the works by Mr. Moriarty, Mr. Darley, and Mr. Ryan, the resident engineer, and also by the contractor and his resident manager.

The quantity of material already placed in the dam is something more than one-third of the whole, and, at the present rate of progress, about three years will be required for its perfect completion.

I do not consider this time too great for the purpose, and fortunately there is no temptation to adopt undue haste, as the water brought into the dam will be available for Sydney, in a greater or less degree, during the whole process of construction.

The inside and outside slopes are those usually adopted for dams of the largest class, and in the case of the excellent materials at Prospect are ample.

The pitching to protect the inner slope against the action of the water and the waves is unusually good, from the heavy, hard character of the stone found on the spot.

The top of the bank (which is a roadway 30 feet wide) is intended to be 8 feet above the level of the waste weir, and will be protected by a substantial wall against any possible injurious wash of the waves.

The local conditions for the construction of a dam of the magnitude of the Prospect Dam are unusually favourable.

The material for the dam itself, and that for the puddle trench, are exactly of the character which an engineer would most desire, and are procured on the site itself, or immediately adjacent.

The mode of executing the work by means of thin layers of earth, consolidated by carts and heavy rollers, and the working of the clay in the puddle trench, indicate careful supervision, both on the part of the engineers and contractor and their respective representatives.

A superficial view of the operations might indeed lead an inexperienced person to the opinion that the mode of carrying on the work was somewhat in excess of necessity, but for a work of such magnitude and importance this great care is well bestowed.

There is one point on which I should like to make a few special remarks.

The site of the dam is on clay of good quality, although of varying thickness, and Mr. Moriarty, or any other engineer, might possibly have been led to the opinion that the puddle trench could have been safely founded upon and worked into this clay.

The failures of important waterworks dams have been very few.

Perhaps the most disastrous in its consequences was the well-known failure of a dam at Sheffield. The consequences were so serious in every respect that the authorities required a special investigation into the cause and circumstances; and I was requested, in conjunction with Mr. La Trobe Bateman and two other engineers, to make this investigation.

The result was, we unanimously agreed and reported that the disaster was occasioned by the sliding of the clay foundation of the dam and puddle trench (under the pressure of a landslip in an adjacent hill) upon the shaly rock beneath.

With the terrible experience of the Sheffield disaster, Mr. Moriarty has acted prudently and well in not depending on the irregular clay foundation for his puddle wall.

By taking his puddle wall into the shale below the clay he has secured absolute safety for his work.

The depth of this puddle wall below the surface varies considerably, and this could only be ascertained as the shale was reached by the excavation; and although the depth on the average exceeds the original contract depth, this contingency could not possibly have been foreseen, and is, fortunately, far less than has frequently been found to be necessary under geological conditions of an analogous character.

I examined personally the character of this shale, and found it a perfectly solid and impervious substance.

It was not unnatural that after the Sheffield disaster it was thought prudent and desirable that other waterworks dams, and works connected with them, in England, should be professionally examined.

I was selected to perform the important duty for the Glasgow Waterworks, in conjunction with Mr. Bateman; and it was a great satisfaction, after minute investigation, that we were able to make a perfectly favourable report, which subsequent experience has confirmed.

With respect to the Prospect Dam, it gives me great pleasure to be able to report that the dam itself, and the masonry, tunnels, and works connected therewith, are of a character worthy of their importance, and creditable to all persons connected with them, and that no anxiety need be entertained of their sufficiency and safety.

I have, &c.,

JOHN FOWLER.

POSTSCRIPT.

It may be interesting to record, in connection with this report on the Prospect Dam, that the puddle trenches of several well-known and successful dams have been taken to a far greater depth into the ground than is being done in the case of the Prospect Dam. For instance—for the Yarrow Reservoir, near Liverpool, the puddle trench was taken 97 feet into the solid, as compared with 50 feet at the Prospect, and many other dams are of greater or equal height, viz.:—the Yarrow Reservoir, with 100 feet above the natural surface; the Grenwith, at Bradford, with 87 feet; the Barden, at Bradford, 80 feet; the Silsden, at Bradford, 88 feet; whilst the Prospect Dam is 83 feet.

There are many others of at least equal height in different parts of the world, and in India several are of greater magnitude as regards cubical contents.—J.F.

Sydney: Thomas Richards, Government Printer.—1880.

1885-6.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

BOTANY WATER SUPPLY DAMS.

(CORRESPONDENCE RESPECTING ALLEGED POLLUTION OF.)

Ordered by the Legislative Assembly to be printed, 4 February, 1886.

The Medical Adviser to the Government to The Principal Under Secretary.

Board of Health Office, 127, Macquarie-street,
Sydney, 13 January, 1886.

Sir,

I have the honor herewith to transmit a report from the Deputy Medical Adviser on the subject of possible pollution of the Sydney water supply from a vast mass of nightsoil which has been deposited in the neighbourhood of the engine-pond at Botany.

The state of matter disclosed is one which cannot fail to produce in the public mind feelings of both disgust and alarm, and I recommend that no time be lost in taking steps to secure the water reserve from all possible pollution.

On Saturday last, when in the neighbourhood of Randwick, I observed a considerable heap of house refuse which had been deposited on a sand-hill on that side of the watershed which drains into the water reserve, and I have no doubt that careful inspection would detect the existence of similar accumulations in other situations equally dangerous. I entirely coincide in the recommendations of the Deputy Medical Adviser, which are practically—(1.) That a careful examination of the whole water reserve should be made at once, with special reference to its boundaries, so as to discover what other filth accumulations, if any, have taken place; and (2.) That this Department should be charged with the duty of keeping up a daily supervision of the whole of the catchment area, so that any future pollution might be at once detected and put a stop to.

I have, &c.,
H. N. MACLAURIN,
Medical Adviser to the Government.

[*Enclosure.*]

The Deputy Medical Adviser to The Medical Adviser to the Government.

12 January, 1886.

It having been asserted that nightsoil had been tipped in dangerous proximity to the Botany dams, I visited the locality pointed out this afternoon, and I have the honor to make the following report and suggestions:—I found the place to be flat, having a south-easterly fall, bounded on the east by the Botany Road, on the south by Blackwater Creek, at a distance from the north boundary, and by a wooded ridge at a less distance from the said boundary, on the south-west and west by the same ridge curving round towards the north, and on the north by Lord's Road. The area of this flat is not large. Its drainage, in the direction of the fall mentioned, renders the land at the foot of the ridge swampy; and at the east end of the ridge (which is abrupt) a small creek begins to form, which turns the ridge, and soon afterwards falls into Blackwater Creek. Blackwater Creek runs from about the point indicated in a course which is parallel with the westerly bank of the engine-pond, and for a long distance close to it. The nightsoil carts have been in the habit of turning off Lord's Road into the bushes which cover the flat, and have there cast their contents on the surface. A very large quantity has been thus thrown down, and the surface covered with the soil is very considerable. It will be washed into Blackwater Creek by the route described at the first heavy rains, and, no doubt, much has been so washed already. Blackwater Creek has for long carried foul water. As its course could not be altered, it was necessary to provide an effectual separation between it and the adjacent engine-pond (which has an area of 50 acres); and this has been done by raising an embankment between the two. This forms the bank of the pond, and is within 2 or 3 feet of the bank of the creek. It will now be clear that the dam is in no danger of direct contamination with this nightsoil, which must enter Blackwater Creek, and that the only question to be asked with regard to the purity of the water supply is: Is the embankment a sufficient barrier, and is it in good order? And these, I believe, are questions for the City Engineer. At present the water in the dam appears to be (and, I am told, is) a little above the level of the creek. To the present height of water, then, the bank is impermeable, for otherwise the level of water within the dam would be lowered. But, after rain, Blackwater Creek would rise, and perhaps above the level of the water within the dam; it would then test another part of the embankment. I observed that the creek is overgrown with weeds, and that the channel is otherwise obstructed; and I think it desirable that, under the circumstances described, it should be cleaned out, and the flow through it rendered as easy as possible. But, with regard to the tipping of nightsoil in this situation, that is an intolerable nuisance, and dangerous to health. There is a considerable number of people near enough to be affected by it, and they complain seriously of it. Further, although it is clear that the soil cannot find its way into the water direct, and although it may be shown that it cannot percolate through the bank, it is at least disgusting that it should be thrown where it must be washed into close proximity to the dams. And, lastly, although it might be freely passed to the bay by the creek, it must there pollute the foreshore, across which the wind blows over the 50 acres of water in the engine-pond. The ease with which

water

water takes up noxious gases from the air around it is well known. In addition, dried and pulverized fœcal matter must, with certain winds, be blown from the flat direct to the water. You have recently drawn attention to the presence of a very considerable heap of dusthole refuse upon the water reserve behind the racecourse at Randwick. The components of this stuff, and of the street sweepings which usually accompany it, are in large proportion organic matters in a state of decomposition. Nightsoil is, of course, popularly known to be obnoxious; but probably it is not known generally that, from many points of view, dusthole refuse is scarcely less objectionable. This heap, then, is at the present moment polluting the town water, and in a way which is not only serious because of its comparatively small size, but if the water reserve is a place recognized by the City Corporation as proper to receive this kind of refuse, there is every probability that upon due search other such heaps may be discovered. It appears to me that in the two circumstances here described there is sufficient evidence that the water supply of this city is not guarded by its legal protectors with scrupulous care. The water reserve should be kept absolutely sacred; upon its cleanness depends the purity of the water, and upon the latter depend the lives of the citizens. I need not dwell upon this. I suggest that measures should be at once taken to ensure the necessary care which at present seems to be lacking. These, it appears to me, might be sufficiently simple:—(1) A survey of the reserve and its marshes might be called for, with a view of removing filth from its surface and its neighbourhood; (2) a sufficient number of rangers might be engaged to keep the whole catchment area under daily supervision; (3) the rangers should not be in the employment of the same body that is charged with the disposal of nightsoil and dust-hole refuse, but should be officers of this department, and should report to you.

J. ASHBURTON THOMPSON, M.D.

Minute of Principal Under Secretary.

Dr. MacLaurin should at once place himself in communication with the Mayor, and make such arrangements as will enable a proper daily supervision to be exercised over the catchment area of the Botany watershed to ensure its being preserved from pollution.

Approved.—JOHN ROBERTSON.

The Principal Under Secretary to The Mayor of Sydney.

Sir, Sydney, 15 January, 1886.

12 Jan. 1886. In transmitting to you the enclosed copy of a letter from the Medical Adviser to the Government, submitting a report on the possible pollution of the water supply of Sydney through certain deposits in the immediate neighbourhood of the engine-pond at Botany, I am directed by the Colonial Secretary to inform you that Dr. MacLaurin has been requested to place himself in communication with you on the subject.

I have, &c.,
CRITCHETT WALKER,
Principal Under Secretary.

The Principal Under Secretary to The Medical Adviser to the Government.

Sir, Sydney, 15 January, 1886.

With reference to your letter of the 13th instant, submitting a report on the possible pollution of the water supply of Sydney through certain deposits in the immediate neighbourhood of the engine-pond at Botany, I am directed by the Colonial Secretary to request that you will place yourself in communication with the Right Worshipful the Mayor of Sydney on the subject.

I have, &c.,
CRITCHETT WALKER,
Principal Under Secretary.

The Medical Adviser to The Government to The Principal Under Secretary.

Sir, Office, 127, Macquarie-street, Sydney, 19 January, 1886.

I have the honor to report that, in compliance with the instructions of the Colonial Secretary, I have this morning had an interview with His Worship the Mayor of Sydney respecting the risk of pollution of the Water Reserve by deposits of night-soil and house refuse.

At the interview were present the City Engineer, the City Health Officer, and the Inspector of Nuisances. After careful consideration it was agreed that an inspection of the whole catchment area of the Water Reserve should take place immediately, under the superintendence of Mr. Trevor Jones, as representing the Mayor, and Dr. Ashburton Thompson, as representing this Department.

The Mayor agreed to appoint a sufficient number of rangers to ensure a satisfactory daily examination of the water area, and to instruct these rangers to report regularly the condition of the Water Reserve to this Department.

I have, &c.,
H. N. MACLAURIN,
Medical Adviser to the Government.

Sydney: Thomas Richards, Government Printer.—1886.

1885-6.

NEW SOUTH WALES.

LANDS FOR PUBLIC PURPOSES ACQUISITION ACT.

(RESUMPTIONS FOR WATER SUPPLY—SYDNEY AND SUBURBS.)

Presented to Parliament, pursuant to Act 44 Vic. No. 16, sec. 6.

NOTIFICATION OF RESUMPTION OF LAND UNDER 44 VICTORIA, No. 16.

NEW SOUTH WALES, to wit. } By His Excellency The Right Honorable SIR AUGUSTUS WILLIAM FREDERICK SPENCER LOFTUS (commonly called Lord AUGUSTUS LOFTUS), Knight Grand Cross of the Most Honorable Order of the Bath, a Member of Her Majesty's Most Honorable Privy Council, Governor and Commander-in-Chief of the Colony of New South Wales and its Dependencies.

(L.S.)

AUGUSTUS LOFTUS, *Governor.*

WHEREAS I, the Governor aforesaid, with the advice of the Executive Council of the said Colony, have duly sanctioned the carrying out of certain works for and in connection with the supply of water to the City of Sydney and its suburbs in the said Colony, for and towards the completion of which said works public funds are available under the provisions of the "Public Works Loan Act of 1879": And whereas the lands hereinafter described are required for the construction of the said works: Now, I, the Governor of the said Colony, with the advice of the Executive Council of the said Colony, in pursuance of the powers in this behalf given to or vested in me by the "Lands for Public Purposes Acquisition Act," do by this notification, published in the Gazette and in a newspaper, that is to say, in the "Sydney Morning Herald," circulated in the Police District wherein the said lands are situated, declare that the lands hereinafter described have been resumed for the public purposes hereinafter mentioned, that is to say, for and in connection with the supply of water to the said City of Sydney and its suburbs, to the intent that, upon the publication of this notification in the Gazette, the legal estate in the said lands shall forthwith be vested in the Minister for Public Works and his successors, on behalf of Her Majesty, for the purpose of the said last-mentioned Act, for an estate of inheritance in fee simple in possession, freed and discharged from all trusts, obligations, estate, interests, contracts, charges, rates, rights-of-way, or other easements whatsoever; and to the intent, further, that the legal estate therein, together with all powers incident thereto, or conferred by the said Act, shall be vested in the said Minister as a trustee, with the powers stated in the said last-mentioned Act. And I declare that the following are the descriptions of the lands hereinbefore referred to, that is to say:—

1. All that piece or parcel of land situated in the parish of Liberty Plains, county of Cumberland, and Colony of New South Wales, containing 6 acres 2 roods 7 perches or thereabout, being part of a grant of 625 acres to Joseph Hyde Potts: Commencing on the eastern boundary of the said grant (which is also the western boundary of 1,340 acres 1 rood 0 Crown Land purchased by the Crown from Messrs. Benjamin and Cohen), at a point bearing north and distan 154 chains 72 links from the south-east corner of the said grant to Potts (being also the south-west corner of the said Crown Land marked by a stone post numbered broad-arrow 27); and bounded on the east by the said Crown Land, being a continuation of the aforesaid boundary bearing north 5 chains 15 links; thence on the north by other part of the said 625 acres grant, as follows:—south 74 degrees 31 minutes west 3 chains 41 links, south 73 degrees 19 minutes west 4 chains 64 links, south 83 degrees 39 minutes west 8 chains 95 links, and north 75 degrees 42 minutes west 8 chains 95 links; thence on the south by land, the property of the Crown, resumed by notification in the Government Gazette of the 21st October, 1881, as follows:—south 65 degrees 23 minutes east 12 chains 51 links, by 2 chains 91 links of a concave curve of 14 chains radius, the chord of which bears south 80 degrees 45 minutes east 2 chains 88 links, by a line bearing north 4 degrees 48 minutes west 1 chain 52 links; thence north 75 degrees 12 minutes east 7 chains 57 links; thence south 4 degrees 48 minutes east 3 chains 3 links; thence by 1 chain 66 links of a concave curve of 14 chains radius, the chord of which bears north 67 degrees 40 minutes east 1 chain 66 links; thence by a line bearing north 63 degrees 32 minutes east, to the point of commencement, and said to be in the possession and occupation of Messrs. Potts and Frazer.

2. All that piece or parcel of land situated in the parish of Liberty Plains, county of Cumberland, and Colony of New South Wales, near Druitt Town, being part of lots Nos. 9, 8, 7, 6, 5, 4, and 3 of a sub-division of a grant of 500 acres to Wm. Roberts: Commencing on the northern side of the Liverpool Road at the south-western corner of lot No. 9; and bounded thence on the west by lot No. 10, bearing northerly 55 links; thence on the north by other parts of the said lots Nos. 9 to 3 bearing north 89 degrees 58 minutes east about 24 chains 40 links to Cook's River; thence on the east by that river southerly about 1 chain; thence on the south by other parts of the said lots Nos. 9 to 3, bearing south 89 degrees 58 minutes west about 22 chains 58 links to the Liverpool Road; thence again on the south by that road westerly, to the point of commencement, containing 2 acres 1 rood 24 perches or thereabouts, and said to be in the possession and occupation of H. Brown, C. Northcote, — Reardon, and others not yet ascertained.

3. All that piece or parcel of land situated in the parish of Concord, county of Cumberland, and Colony of New South Wales, being part of lot No. 11 of 9 acres of the Redmyre Estate, contained in certificate of title, vol. 180, folio 28: Commencing on the western side of the Homebush Road, at a point bearing north 2 chains 19 links from the north-east corner of lot No. 12 of the said estate; and bounded thence on the south by other part of said lot No. 11 bearing west 14 chains

86 links; thence on the west by land of J. F. Josephson bearing north 1 chain; thence on the north by other part of the said lot No. 11 bearing east 14 chains 86 links to the Homebush Road; thence on the east by that road bearing south 1 chain, to the point of commencement, containing 1 acre 1 rood 37¾ perches or thereabouts, and said to be in the possession and occupation of A. Hancock and Dr. Foucart.

4. All that piece or parcel of land situated in the parish of Petersham, county of Cumberland, and Colony of New South Wales, being part of a grant of 100 acres to John Thomas Prentice, called "Hammond Hill Farm": Commencing on the western side of the Balmain Road at a point distant 273 feet and bearing northerly from the intersection of the said western side of the Balmain Road with the northern side of the Parramatta Road; and bounded thence on the east by the Balmain Road bearing northerly 231 feet; thence on the north by C. Hearn's land bearing south 77 degrees 23 minutes west about 190 feet 9 inches; thence on the west by the Elswick Estate bearing south 2 degrees 15 minutes east 234 feet 9 inches; thence on the south by lands of C. Hearn and — Gale bearing north 77 degrees 23 minutes east about 227 feet, to the point of commencement, containing 1 acre 0 roods 17¾ perches, or thereabouts, and said to be in the possession and occupation of C. Hearn.

In witness whereof I have hereunto set my Hand, and caused the Great Seal of the Colony to be hereto affixed, at Government House, Sydney, this sixth day of October, in the year of our Lord one thousand eight hundred and eighty-five, and in the forty-ninth year of Her Majesty's Reign.

By His Excellency's Command,

F. A. WRIGHT.

GOD SAVE THE QUEEN!

Sydney: Thomas Richards, Government Printer.—1885.

[3*d*.]

1885–6.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

TEMPORARY WATER SUPPLY FOR SYDNEY.

(PAPERS.)

Ordered by the Legislative Assembly to be printed, 26 November, 1885.

SCHEDULE.

TEMPORARY WATER SUPPLY FOR SYDNEY.

No. 1.

The Engineer-in-Chief to The Secretary, Gaslight Company.

Sir, Harbours and Rivers Department, Sydney, 9 May, 1885.

Would you kindly inform me if your Company could lend 250 lengths of 30″ main in the event of their being required in connection with the Sydney Water Supply.

I have, &c.,
E. O. MORIARTY.

No. 2.

The Secretary, Gaslight Company, to The Engineer-in-Chief.

Sir, Australian Gaslight Company's Office, Sydney, 12 May, 1885.

I do myself the honor to acknowledge the receipt of your letter of the 9th instant, inquiring if this company could lend 250 lengths of 30″ main for the water supply, and to inform you in reply that we do not use this size of pipe and consequently have none in stock.

I have, &c.,
W. JOHNSTON,
Secretary.

Seen. What are the largest pipes the company have, and whether they might be able to lend in case of their being required in the event of a water famine in Sydney? Write.—E.O.M., 12/5/85. Wrote.—J.W., 14/5/85.

No. 3.

The Engineer-in-Chief to The Secretary, Gaslight Company.

Sir, Harbours and Rivers Department, 14 May, 1885.

I have to acknowledge the receipt of your letter of the 12th instant, stating that your Company do not use 30-inch mains, and should now be glad, if you would kindly inform me, what are the largest pipes your company have and the number you might be able to lend in case of their being required in the event of a water-famine in Sydney? I have, &c.,
(for E. O. MORIARTY),
J. BARLING.

No. 4.

The Secretary, Gaslight Company, to The Engineer-in-Chief.

Sir, Australian Gaslight Company's Office, Sydney, 19 May, 1885.

I have to acknowledge receipt of your letter of the 14th instant, and in reply thereto beg to say that we have 36-inch pipes, imported for our trunk main now being laid from the Mortlake Station, and of these 1,000 to 2,000 yards can be spared if satisfactory arrangements can be made with the contractor for suspending his contract for a few months.

If this can be done the directors are willing to sell the pipes to the Government at once.

The directors prefer to sell the pipes, because when parted with to the Government it will be necessary for them to cable for a fresh supply for the contractor's work, but if lent and returned the Company would be forced to keep a size in stock which is very rarely used.

I have, &c.,
W. JOHNSTON,
Secretary.

No. 5.

The Secretary of Gaslight Company to The Engineer-in-Chief.

Sir, Australian Gaslight Company's Office, Sydney, 21 May, 1885.

In reply to your telephone message of yesterday I beg to say that the 36-inch pipes weigh 38 cwt. each, and the charge will be £6 6s. (six pounds six shillings) per ton, delivered at our Mortlake Works, on the Parramatta River. I have, &c.,
W. JOHNSTON,
Secretary.

Submitted.—1st June, 1885. The Minister for Works.—A.S., 2/6/85. The Under Secretary for Public Works.—B.C., 2 June, /85. J.B. for P.U.S. Submitted.—J.R., 3/6/85.

No. 6.

The Engineer-in-Chief to the Under Secretary for Public Works.

Sir, Department of Public Works, Harbours and Rivers Branch, Sydney, 28 May, 1885.

I have the honor to state, for Mr. Secretary Wright's information, that in company with Mr Jones, the City Engineer, I have examined the state of the Botany watershed, as well as some other sources from which the present supply may be supplemented in the event of a continuance of the present unusually dry weather. At

At the time of our visit on the Botany watershed all the reservoirs might be said to be exhausted, and the supply to the city was dependent on the Lachlan stream, which showed about ½ million gallons flowing into the tunnel, and on about 4¼ million gallons passing over the gauge-board near Botany per day. Since the date of our visit, about three weeks ago, the stream has fallen off a little, and now shows about 3¾ million gallons per day, which is a better condition of the supply than obtained in April, 1881, when the stream fell short of what it is at present.

Any further falling off will, judging from all previous experience, be gradual and slow.

The judicious measures which have been adopted by the Mayor and City Engineer to diminish waste have had the effect of bringing the consumption within the supply, without, as a rule, subjecting the citizens to any very serious inconvenience, and I have no doubt, that with more experience of the working of the intermittent system, aided by the increased supply which may be obtained, if required, from other sources, that there is no reason to apprehend anything in the shape of a water famine, at all events for the present.

But, although there may not be any great reason to apprehend an immediate failure of the supply, it is perhaps right that we should consider what steps should be taken to provide against the effect of a dry winter and spring.

If such should occur there can be little doubt but that the Botany stream would fail to supply the requisite quantity, and the citizens might be subjected to much inconvenience if entirely dependent on it. It might therefore be worth while considering about obtaining a supply from the Nepean and Cataract Rivers, by means of temporary flumes and pipes; and I have had estimates prepared for a project of this kind.

With the exception of the permanent flumes, the contract for which has been taken in England, the permanent works, that is to say, about 46 miles in length of the permanent work of the canal and tunnels may be said to be completed, so that in a short time the water of the Nepean may be let down to within about 16 miles of Sydney.

Of the remaining portion, tenders for the wrought-iron pipes, 4½ miles, are to be received in July next, and a contract has been entered into for the supply of 11½ miles of 48″ and 42″ cast-iron pipes required to deliver the water to Crown-street, some 1,000 tons of which were shipped early in April.

But as the permanent work would not be ready in time it may be worth considering the expediency of bridging the uncompleted portion by means of temporary fluming and piping, and I have had estimates prepared of the cost of doing so.

As regards the temporary works down to Pott's Hill, that is to say, to within 11½ miles of Sydney, which are estimated to cost about £30,307, the whole would be rendered unnecessary in the event of a moderately heavy fall of rain occurring.

But the 11½ miles of 18-inch pipes, which I estimate at £41,400, would not be wasted, as they would come in for the reticulation of the western suburbs after the permanent works are completed.

These pipes would deliver about 2½ million gallons per day into the engine pond in Botany, from which it might be pumped to Crown-street.

I mention this arrangement because of the much larger body of water the pipes would deliver to the low lands of Botany than would be possible to Crown-street.

The flumes, which would consist of a corrugated iron trough supported on a framing of oregon timber, would be capable of carrying 17½ million gallons per day, and the sheet-iron pipes across Duck Creek would carry 9½ million gallons per day.

I refrain from making any recommendation in favour of or against undertaking these temporary works, and have confined myself to sketching out what might be done to provide against the effect of a dry winter and spring. The Minister for Works is quite as capable, as I can claim to be, of forming a judgment of the probability or otherwise of the continuance of the present drought; but I may state that my own belief is that we shall have rain before the winter is out.

I may add in conclusion that I have had the advantage of discussing the question of water supply with the Railway authorities, and am therefore in a position to be able to state, that should the city be driven to extremities, without having recourse to the more expensive projects, the Railway Department would be able, with a very moderate outlay of about say, £5,000, to bring from Penrith about 1,000,000 gallons of water per diem, which would very materially supplement the Botany supply, should that be reduced to the lowest ebb.

The water thus brought from the Nepean by train could be easily pumped into the Crown-street Reservoir, and distributed through the present city reticulation.

I have, &c.,
E. O. MORIARTY,
Engineer-in-Chief for Harbours and Rivers.

Veteran Swamp.

P.S.—In company with the Hon. Richard Hill, and Mr. McElhone, M.P., I visited the Veteran Swamp, which flows into Botany Bay about half-a-mile beyond the "Sir Joseph Banks Hotel," and where, judging from the eye, I should say nearly a million gallons of water were flowing. If the water should be found on analysis to be good, which it appears to be, it might without difficulty, and at a trifling cost, be pumped into the engine pond.

No. 7.

The Town Clerk, Sydney, to The Principal Under Secretary.

Sir, Town Clerk's Office, Sydney, 28 May, 1885.

In view of a resolution of the City Council to construct a temporary water supply by pipes or flumes from the Nepean River near Penrith, I have the honor, by direction of the Right Worshipful the Mayor, to request that the Government will confer the necessary powers on the Council, or take such action in carrying out works in the above behalf, as the Government may deem fit to carry out the views of the Council in mitigating the severity of the present drought as it effects the residents of the city and suburbs.

I have, &c.,
HENRY J. DANIELS,
Pro Town Clerk.

No. 8.

1000

No. 8.

The Engineer-in-Chief to The Secretary, Gaslight Company.

My dear Sir, Harbours and Rivers Department, Sydney, 30 May, 1885.

In case of the Government requiring them, would you kindly let me know how many, if any, 18-inch pipes you could supply us with now, and say within the next two months.

Yours, &c.,
E. O. MORIARTY.

No. 8A.

The Engineer-in-Chief to The Under Secretary for Public Works.

Department of Public Works, Harbours and Rivers Branch, Sydney, June, 1885.

In view of the Government undertaking some temporary works for bringing the waters of the Nepean down to Sydney, I have made inquiry of the Gas Company as to their ability to supply us with some 3 feet pipes, of which we should require about 2,000 yards.

The company have most courteously and liberally offered to place that quantity at the disposal of the Government, at the price of £6 6s. per ton, which must be about their cost price to the company landed here.

If Mr. Secretary Wright approves of the company's offer being accepted, which I would recommend, the laying of the pipes might be commenced immediately.

E. O. MORIARTY.

Submitted.—J.R., 2/6/85. Approved.—Let me know what steps are to be taken in laying the pipes.—F.A.W., 3/6/85.

No. 9.

The Engineer-in-Chief to The Under Secretary for Public Works.

As Messrs. Hudson Bros. have taken considerable trouble in this matter, and have identified themselves with the project, I would beg to recommend that they be asked to give a price for removing the pipes to the sites where they will require to be placed, and laying and jointing them.

E.O.M.,
4/6/85.

Harbours and Rivers.—J.R., B.C., 4 June, 1885. Urgent.—B.C., Under Secretary, Public Works.

No. 9A.

The Engineeer-in-Chief to Messrs. Hudson Brothers.

Sir, Harbours and Rivers Department, Sydney, 10 June, 1885.

With reference to your offer to bring a temporary water supply into Sydney, I do myself the honor to ask, if you include in that offer, the cost of conveying the 36-inch pipes from where they now lie, to the sites where they are to be laid.

I have, &c.,
E. O. MORIARTY.

(Memo.—Hudson Bros. replied, the cost was not included in their offer. Letter not with papers.)

No. 10.

Mr. J. Y. Mills to The Minister for Works.

Sir, Sydney, 1 June, 1885.

During the past few days I visited the Pheasant's Nest and saw a stream of clear sparkling water from the Nepean and Cordeaux Rivers, as large as all streams in the various races at Botany put together, running to waste through the sluice of the dam. It was strong enough to leap over boulders 18 inches high.

In order to assist any one whom you may authorise in saving this and turning it into the Prospect Reservoir, which can now hold behind the finished portion of the dam nearly 70,000,000 gallons, and in a short time will hold 100,000,000, I will lend 400 men for a fortnight or 200 men for a month, with twenty-five horses and carts from the dam work, to help in constructing the only half-mile of temporary fluming required to complete the canal from the Pheasant's Nest to Prospect. I am also willing, if necessary, to pay one-third of their wages for the period named; this, with the 30-inch main connecting the canals above and below the dam, will complete the canal to within 2¼ miles of Granville Railway Station, a fact not generally known.

In our present distress such a storage of water at the nearest possible point to Sydney, and at an elevation of nearly 140 feet above sea level, would, I think, be a consolation to all concerned.

I have, &c.
J. Y. MILLS.

No. 11.

The Secretary, Gaslight Company, to The Engineer-in-Chief.

Australian Gaslight Company's Office, Sydney, 2 June, 1885.

Sir,

In reply to your letter of the 30th instant, I find we have no 18-inch pipes in stock; but in the "City of York," to arrive about the end of this month, we have 400 pipes, which the directors are willing to sell to the Government at £6 16s. 2d. per ton, if taken from the ship's side.

Please say at once whether you will take them, as it will be necessary for us to cable for a fresh supply to meet the urgent demands for gas, for which these were imported.

Referring to my letter of the 21st ultimo, respecting the 36-inch pipes offered to the Government, I am now in possession of Mr. Kinshela's (the contractor for laying our trunk main) letter expressing his willingness and consent to delay the execution of his contract for the purpose of aiding the Government in providing a water supply. In the meantime, however, he is using up these large pipes, and it will therefore be necessary for you, if you require them, to take the quantity offered at once.

Yours, &c.,
W. JOHNSTON,
Secretary.

No. 12.

Engineer-in-Chief's Memo.

If the Minister should decide on undertaking a temporary supply of water from the Nepean, I would beg to recommend the purchase of the within-mentioned pipes from the Gas Company.—E.O.M., 3/6/85.

No. 13.

Engineer-in-Chief to The Under Secretary for Public Works.

Harbours and Rivers Branch, Sydney, 29 May, 1885.

In reference to the proposal to provide a temporary water supply for Sydney, I would beg to suggest that the following cablegram be sent to the Agent-General:—"How soon could you procure and ship 5,000 tons, 18-inch pipes, ¾-inch thick."

E. O. MORIARTY.

Very urgent.

Submitted.—J.R., 29/5/85. Cablegram sent, 29/5/85. Approved.—F.A.W., 29/5/85. Mr. Moriarty.—J.R., B.C., 29/5/85.

No. 14.

Cablegram to Agent-General.

Department of Public Works, Sydney, 29 May, 1885.

Will the Principal Under Secretary please cause the following cablegram to be transmitted to the Agent-General, in London, viz.:—"How soon could you procure and ship 5,000 tons, 18-inch pipes, ¾-inch thick."

J.R.

The Principal Under Secretary, B.C., 29 May, 1885. See telegram, 29. Tel. to Agent-General, 30 May, 1885. The Under Secretary for Public Works.—J.B. (for P.U.S.), B.C., 30 May 1885. Harbours and Rivers.—J.R., B.C., 3 June, 1885.

No. 15.

Telegram from Agent-General to Colonial Secretary.

2 June, 1885.

Cochrane, Grove, and Company will supply five thousand tons, eighteen-inch pipes, in six months, at the rate of two hundred tons per week, price for an immediate order, four pounds, f.o.b. Middlesboro coated twelve feet lengths, London, seven shillings and six-pence extra.

Harbours and Rivers.—J.R., B.C., 4 June, 1885.

No. 15A.

The Engineer-in-Chief to The Secretary, Gaslight Company.

Harbours and Rivers Department, Sydney, 9 June, 1885.

Sir,

With reference to my telephone message to you of a few days ago intimating that the Minister for Works accepted your offer to supply 2,000 yards of 36-inch pipes, I now confirm the same, and at the same time, am to express the thanks of the Department for your generous offer.

I have, &c.,
E. O. MORIARTY.

No. 16.

No. 16.

Managing Director, Hudson Bros. (Limited), to The Secretary for Public Works.

B.

Sir,

Redfern Works, 4 June, 1885.

With reference to our several interviews respecting the construction of works necessary for a temporary supply of water to Sydney, in connection with the works already completed for the permanent supply from the Pheasant's Nest, on behalf of this Company I have now the honor to submit the following proposal:—

We will lay the 36" pipes you have secured from the Gas Company, across the several creeks necessary to connect the flow of water from the upper works above Prospect with the canal below Prospect, then convey the water in flumes (as proposed by the Engineer-in-Chief) to a spot known as Ettenger's, from thence to the proposed reservoir at Pott's Hill with the 36" pipes you have purchased from the Gas Company, and from the Pott's Hill reservoir by pipes 20 inches diameter, made of sheet iron, to the Botany Dams. These pipes we will supply and lay along the streets from Pott's Hill to Botany Dams, with the option of going through private property where it would be more convenient if we can get the consent of the property owners.

We will provide for carrying 3 million gallons per day in all the work we do, and will complete our contract in four months for the sum of sixty-five thousand pounds say (£65,000).

I have, &c.,

(for Hudson Brothers (Limited),

HENRY HUDSON,

Managing Director.

This is the tender or letter marked B referred to in our annexed bond to Her Majesty the Queen, dated on 3rd day of September, A.D. 1885.

Henry Hudson, Managing Director.
Fred. Thos. Humphrey.
Sam. W. Gray.
John Woods.
James C. Alexander.

Witness—
John Portus.

I recommend the adoption of this proposal of Messrs. Hudson Brothers to my honorable colleagues. —F.A.W., 9/6/85.

Cabinet having considered the highly important subject of water supply, and having consulted Mr. Moriarty and ascertained that this temporary mode of bringing the Pheasant's Nest Water Supply to Botany would not cause any interruption to the main works, and that if the temporary is not required for Sydney, owing to the breakage up of the drought, the upper portion of the proposed works can be utilized by helping to fill the permanent dam, decides that the offer of Messrs. Hudson Brothers (Limited) be accepted.—A.S., 8/6/85.

Mr. Moriarty will please make the necessary arrangements for carrying out the details of this work under a proper contract with the Messrs. Hudson Brothers.—F.A.W., 10/6/85. Harbours and Rivers, J.R., B.C., 10 June, 1885.

I suppose the Under Secretary has informed Messrs. Hudson Brothers of the acceptance by Government of their offer in this matter. I would request to be informed of the date of such acceptance in order that I may insert the time of completion in the contract which is now ready for signature.—E.O.M., 19/6/85. B.C., Under Secretary for Public Works.

There seems to have been no written acceptance; the matter was arranged verbally by the Minister, but the contract will now cover the whole matter, I presume.—E.O.M., 21/7/85.

No. 17.

Hudson Bros. (Limited) to The Engineer-in-Chief for Harbours and Rivers.

Granville, 20 June, 1885.

Be kind enough to supply us with reduced levels of B.M.'s along line of temporary water supply, more especially at present of that part of the line between 4 in 3,900 to 6 in 4,000; also, as soon as convenient, plan of the line.

(*pro* A. Chaplin.)
HUDSON BROS. (Limited).

Mr. Darley, for E.O.M.—J.B., 22/6/85. Urgent.

Herewith is a tracing in three sheets, showing the levels on each 100-feet peg from 4 miles 4,000 feet to 6 miles 3,000 feet, being the length proposed to be covered by a raised timber and iron flume. Messrs. Hudson Bros. should be instructed to keep the centre of this flume at least 30 feet clear of the centre line, as pegged out.—C.W.D., 22/6/85. Inform.

No. 18.

No. 18.

The Managing Director, Hudson Bros. (Limited), to The Secretary for Public Works.

C.

Sir, Redfern Works, Sydney, 13 July, 1885.

Referring to the inability of the Department to supply about 3 miles of 36-inch cast-iron pipes for which our contract for the temporary water supply provides, we desire to say that our company is willing to make the 30-inch wrought-iron pipes and substitute them for the deficient 36-inch cast-iron pipes, in terms of the contract, as now prepared by the Engineer-in-Chief for Harbours and Rivers, without asking for any additional payment; but it is to be distinctly understood that this extra work and material, involving, as it must, a cost of several thousand pounds, will only be incurred by us because we do not wish to embarrass you in any way with regard to this contract, and also to show we are determined to successfully carry through the undertaking entrusted by you to us.

We need hardly point out that this extra work coming upon us so unexpectedly, and so long after our offer was accepted, has entirely upset our calculations and business arrangements.

We therefore stipulate that should we on our part, from circumstances which we cannot control, be somewhat behind time in completing the contract, you will, on your part, in all fairness, show us some consideration, bearing in mind that we shall now have to procure from England 300 tons of wrought-iron plates of larger size and heavier gauge to those for which we cabled just a month ago.

We give you our assurance that every effort will be made to get the work done in time. The only impediment which threatens us is the possible delay in the execution of this further order for iron, which is not a stock size. We have cabled to our London Agents to spare no expense in procuring the iron promptly, and ship it by the fastest steamers on the berth.

I have, &c.,
for Hudson Bros. (Limited),
HENRY HUDSON,
Managing Director.

This is the letter marked C referred to in our annexed bond to Her Majesty the Queen, dated the 3rd day of September, A.D. 1885.

HENRY HUDSON,
Managing Director.

No. 19.

The Secretary for Public Works to Messrs. Hudson Brothers.

Dear Sir, Sydney, 15 July, 1885.

In reply to your letter of the 13th, I can only assure you in writing, as I did verbally, that in the matter of your contract you will receive every consideration and justice at my hands. I am aware of the extreme expense you have been put to, and fully appreciate your spirited enterprise in determining to push on with the work to its completion notwithstanding its increased cost to yourselves.

Believe me, &c.,
F. A. WRIGHT.

No. 20.

Minute from The Engineer-in-Chief to The Under Secretary for Public Works.

H. & R. Dep., 17–22/7/85.

Minute Paper.—Forwarding papers in connection with Messrs. Hudson Bros.' contract for the Temporary Water Supply for Sydney.

Enclosed will be found the specification and tender for Messrs. Hudson Bros.' (Limited) contract in connection with the temporary water supply for Sydney.

I suggest that these documents be forwarded to the Crown Solicitor, to enable him to prepare the necessary bond.

As the contract is somewhat of an unusual character it will probably require a special bond to meet the case.

In the specification reference is made to the peculiar features of the case, and an effort has been made to embrace them therein. The specification probably covers wider ground than the tender does, but this has been done advisedly, with the concurrence of the Messrs. Hudson.

I would suggest therefore that in the bond specific reference be made to that aspect of the case, viz., that the company are bound to carry out the work embraced in the specification, although it may not be held to be included in the tender; in other words, to give effect to the arrangement that wherein possibly the tender may be deficient the specification shall hold good, and *vice versâ*.

E. O. MORIARTY.

Submitted.—J.R., 23/7/85. Forwarded to Crown Solicitor, to prepare bond.—F.A.W., 25/7/85.

No. 21.

The Crown Solicitor to The Under Secretary for Public Works.

Sir, Crown Solicitor's Office, 28 July, 1885.

I have the honor to return herewith the papers relating to the contract with Messrs. Hudson Brothers for the temporary water supply for Sydney, and to request that you will inform me whether the specification was prepared after the tender of Messrs. Hudson Bros. had been accepted, the Messrs. Hudson agreeing to accept same as defining the work to be done under their contract, or, in the usual way, prior, to the tender being sent in; and if the former was the case, that you will also state to what description of the work to be done the tender was applicable if same was in any way stated.

I have, &c.,
JOHN WILLIAMS,
Crown Solicitor.

Submitted.—J.R., 29/7/85. Mr. Moriarty for report.—F.A.W., 29/7/85.

No. 22.

The Engineer-in-Chief to The Under Secretary for Public Works.

The tender, so far as I know, was never formally accepted in writing, but the specification was prepared after the verbal acceptance of the tender by the Minister. I have pointedly alluded to this in page 25 of the specification. The tender generally embraces the work to be done, but there are details in the specification which perhaps a strict reading of the tender would seem not to be included therein; hence my desire to make the specification the foundation of the bond rather than the tender.

E. O. MORIARTY,
4/8/85.

Submitted.—J.R, 5/8/85. Forwarded to Crown Solicitor.—F.A.W., 6/8/85.

No. 23.

Crown Solicitor to Under Secretary for Public Works.

Sir, Crown Solicitor's Office, Sydney, 10 August, 1885.

I have the honor to return herewith the papers relating to the contract with Messrs. Hudson Brothers for the temporary water supply for Sydney, and to request that I may be furnished with the plans and the names of the sureties.

I have, &c.,
JOHN WILLIAMS,
Crown Solicitor.

There are no plans. Hudson Bros. for names of sureties.—12/8/85.

The Under Secretary for Public Works to Messrs. Hudson Bros.

Gentlemen, Department of Public Works, Sydney, 12 August, 1885.

Referring to your contract for providing temporary water supply for Sydney, I am directed to request that you will have the goodness to furnish me with the names, &c., of the sureties you propose to join in your bond for the above contract.

I have, &c.,
JOHN RAE.

No. 25.

Hudson Bros. to The Under Secretary for Public Works.

Sir, Redfern Works, Sydney, 14 August, 1885.

In reply to your letter of the 12th instant, asking for the names of the sureties we propose to enter into the bond for the performance of our contract for the temporary water supply for Sydney, I have the honor to submit the names of John Woods, Esq., of Fairlight, Manly, and James Carnegie Alexander, Esq., of 31, Hunter-street.

I have, &c.,
HENRY HUDSON,
Managing Director, Hudson Bros. (Limited).

Submitted, 17/8/85. Mr. Moriarty for report.—J.R., B.C., 17/8/85. Sureties sufficient, there are no plans. M.P., 85/1564 should be placed with the contract documents.—E.O.M., 19/8/85. B.C., Under Secty. P. Works. Approved.—F.A.W., 21/8/85. Forwarded to Crown Solicitor, 21/8/85. Inform Mr. Hudson in terms of the above.—E.O.M., 24/6/85. Seen; plan received.—H.H., 24/6/85.

No. 26.

No. 26.

The Assistant Engineer to The Engineer-in-Chief.

Harbours and Rivers Office, Sydney, 20 August, 1885.

I RECOMMEND that the attached tracing be forwarded to Messrs. Hudson Bros. with a request that the 20-inch temporary pipe be kept at least 56 feet from peg No. 5, at Pott's Hill, so that it may be clear of works in connection with the filtering tank about to be erected. The tracing shows in outline the position and size of the tank.

I understand this portion of the pipe is already laid; if so, I think it can be easily moved by breaking one joint and rolling into a new trench.

C. W. DARLEY.

Inform Mr. Hudson accordingly.—E.O.M., 20/8/85. Mr. Hudson has taken the plan himself to-day.—J.B., 20/8/85. Let Mr. Blomfield see this.—J.B., 20/8/85. Seen.—H.A.B., 21/8/85. I visited this place to-day. Nothing has been done yet in the way of moving the temporary wooden tank or pipe.—H.A.B., 24/8/85. Let Mr. Darley see.—J.B., 25/8/85. Seen.—C.W.D., 25/8/85.

No. 27.

Messrs. Hudson Bros. to The Under Secretary for Public Works.

Redfern, 21 August, 1885.

Sir,

I have the honor to request you will be good enough to authorise the payment of £10,000 on account of the contract for the temporary water supply.

It may be urged that the bond is not yet signed, but I would beg to point out that I have called three times at the Crown Law Offices on the subject, and have been informed that the document is not yet ready. As we have paid away now about £20,000 on this work I shall be obliged if you will be good enough to authorise the advance now asked.

I have, &c.,
HENRY HUDSON.

I see no objection to this; has Mr. Moriarty any?—F.A.W., 24/8/85. J.R.—B.C., 24/8/85.

No. 28.

The Engineer-in-Chief to The Under Secretary for Public Works.

As I have inspected the works myself, I am glad to be able to recommend a compliance with this request. I presume Mr. Hudson will furnish me with a voucher in the usual way, and I should be glad to be informed to what fund the account is to be charged.—E.O.M., 25/8/85.

B.C., Under Secretary for Public Works.

Charge to £553,000 vote, further Sydney Water Supply, 1884, in anticipation of separate vote.—J.R., 27/8/85.

No. 29.

The Crown Solicitor to The Under Secretary for Public Works.

Crown Solicitor's Office, 25 August, 1885.

Sir,

I have the honor to inform you that in compliance with your instructions I have had prepared, and forward herewith, the bond for the completion of the Sydney Temporary Water Supply, in order that same may be perused by the Engineer-in-Chief for Harbours and Rivers, and, if approved of, executed by Hudson Brothers (Limited), and its sureties, and stamped, the amount of stamp duty payable being £1 2s. All the other papers herein are returned herewith.

I have, &c.,
JOHN WILLIAMS,
Crown Solicitor.

Mr. Moriarty.—J.R. B.C., 29/8/85.

Bond has now been signed and stamped, and is retained in my possession.—E. O. MORIARTY, 14/9/85.

B.C., Under Secretary for Public Works.

No. 30.

Messrs. Hudson Bros. to The Engineer-in-Chief.

Redfern Works, 8 September, 1885.

Sir,

I have the honor to request you will be good enough to certify for a further payment to this company of the sum of £10,000 on account of work completed in connection with our contract for the temporary water supply.

I have, &c.,
HENRY HUDSON,
Managing Director, HUDSON BROS. (Limited).

Mr. Darley for report, for E.O.M.—J.B., 8/9/85.

No. 31.

Report of The Assistant Engineer on Progress of Work.

FROM what I have seen I think work to the value of about £25,000 has been performed, but should not the vouchers be made out in the usual way with a deduction for percentage? I believe the Minister fixed the percentage at 25 per cent. to be held.

C.W.D.,
9/9/85.

No. 32.

The Assistant Engineer to The Engineer-in-Chief.

I FIND that about fourty-two more 12-feet lengths of 36-in. pipes are required to close the aqueducts, and as the Gas Company are unable to supply any more, I recommend that Messrs. Hudson Bros. (Limited) be requested to furnish a price for making them of wrought-iron.

About 504 feet will be required exclusive of joint laps.

Messrs. Hudson Bros. (Limited) should also be instructed to provide sufficient 30-in. pipe to close up the gap of 1,200 feet across the Duck Creek, which was to have been laid with cast-iron pipes, but as these cannot now be obtained from the Gas Company the wrought-iron pipes had better be made.

C. W. DARLEY,
24/9/85.

Inform Messrs. Hudson Bros. and request them to forward a price for the pipes.—E.O.M., 24/9/85.

No. 33.

The Engineer-in-Chief to Messrs. Hudson Bros.

Gentlemen, Harbours and Rivers, 25 September, 1885.

I shall be glad if you would kindly furnish me at your earliest convenience with a price for, say, 504 feet exclusive of joint laps of 36-inch wrought-iron pipes sufficient to close the aqueducts in connection with the temporary water supply.

I have also to request that you will provide sufficient 30-in. wrought-iron pipes to close up the gap of 1,200 feet across Duck River.

I have, &c.
(for E. O. MORIARTY),
J. BARLING.

No. 34.

Messrs. Hudson Bros. to The Engineer-in-Chief.

Sir, Redfern, 30 September, 1885.

In reply to your letter, dated the 30th instant, asking for a price for the remainder of the 36-inch pipes required to close the aqueducts in connection with the temporary water supply, I beg to say we are prepared to supply these pipes, delivered on trucks in our siding, for twenty-four shillings (24s.) per lineal foot.

I have, &c.,
(For HUDSON BROS.),
HENRY HUDSON,
Managing Director.

The price quoted, 24s. per foot, is, I think, rather high, being in excess of the cost of the cast-iron pipes. The latter cost just 22s. per foot, and I believe Messrs. Hudson Bros. will accept the rate under the circumstances if written to offering it, the order to proceed with the work might at the same time be given.—C.W.D., 7/10/85.

The Engineer-in-Chief, Harbours and Rivers. Write to Messrs. Hudson Bros. offering 22s. per foot run.—E.O.M., 7/10/85. Write at once.—J.B., 8/10/85.

No. 35.

The Engineer-in-Chief to Messrs. Hudson Bros.

Gentlemen, Harbours and Rivers, 8 October, 1885.

With reference to your letter of the 30th ultimo, offering to supply the remainder of the 36-inch pipes required to close the aqueducts at the rate of twenty-four shillings (24s.) per lineal foot, I beg to inform you that I am prepared to recommend that twenty-two shillings (22s) per lineal foot be paid for the pipes.

If you are disposed to supply them at this rate please let us know at once.

I have, &c.,
(for E. O. MORIARTY),
J. BARLING.

No. 36.

Messrs. Hudson Bros. to The Engineer-in-Chief.

Sir, Redfern, 12 October, 1885.

I have the honor to acknowledge receipt of your letter of 8th October, stating that you consider 24s. per lineal foot for the 36-inch pipes rather high, but that you are prepared to recommend 22s. per lineal foot being paid for same. As we are very anxious to get the work in hand, we are willing to accept 22s. per lineal foot as proposed by you.

We

We will use every effort to get these pipes made promptly, and feel sure we receive some consideration as regards time for the extra work entailed in making these pipes, as well as the 1,200 feet for Duck River.

I have, &c.,
(for HUDSON BROS., (Limited),
HENRY HUDSON,
Managing Director.

Carry out.—E.O.M., 13/10/85. Accept, done.—J.B., 11/10/85. Messrs. C.S. to note,—J.B., 14/10/85. Noted.—J.C., 15/10/85. S.S., 1/910/85.

No. 37.

The Engineer-in-Chief to Messrs. Hudson Bros.

Gentlemen, Harbours and Rivers Department, Sydney, 14 October, 1885.

I do myself the honor to accept the offer contained in your letter of the 12th instant to supply the 36-inch pipes required to close the aqueducts at the rate of twenty-two shillings (22s) per lineal foot.

I have to ask you to be good enough to have the work put in hand at once.

I have, &c.,
(for E. O. MORIARTY),
J. BARLING.

The work completed comprises four of the aqueducts, 2 miles of timber flumings, 3 miles of 22-inch pipe laid, and 1 mile of 22-inch pipe made ready for laying.—C.W.D.

See voucher 4013, September, 1885, for £8,750.—S.S., 10/9/85.

No. 38.

The District Engineer to The Engineer-in-Chief.

Sir, Sydney Water Supply, Campbelltown, 1 October, 1885.

In accordance with your memorandum, received on the 23rd ultimo, I have the honor to report that your instructions regarding the laying of pipes were forwarded to Messrs. Hudson Bros. on the 24th ultimo.

Previously, written instructions on the same subject were given on the 18th July, 31st August, 11th September, and 18th September.

In addition I have constantly given verbal instructions to the same effect, and cautioned them against deviating from the plans and specifications.

Although Messrs. Hudson Bros. promised to attend to these instructions they practically disregarded them, and instead of the work complained of being rectified it is being completed, and new work is being done in an equally unsatisfactory manner.

In many places the pipes are being laid almost on bed-level and close to sides of cutting, and even where walling has to be built.

The concrete dams being constructed across the canal are in some places insufficiently high and very thin, and although some of the concrete used is now in three weeks it is still quite soft, and does not appear to be setting.

The timber work is not altogether satisfactory either on account of bad joints, omission of bolts, and pipes not resting on bearers, &c.

I should, therefore, be greatly obliged if you would take an early opportunity of satisfying yourself as to the correctness of my report, and of dealing with the matter accordingly.

I have, &c.,
J. GRIMSHAW,
Res. Eng.

No. 39.

The District Engineer to The Engineer-in-Chief.

As the Engineer-in-Chief passed over the upper portion of work (September 30) and saw its condition, it would perhaps be better if Hudson Bros. received notice direct from head office, to which they will probably then attend.

D.H.,
3/10/85.

B.C., Engineer-in-Chief.

No. 40.

The Assistant Engineer to The Engineer-in-Chief.

I THINK Hudson Bros., attention should be called to this matter at once, they have been repeatedly spoken to and requested to keep the pipes at least 18 inches off the bottom as well as clear out from the walls. It will be a difficult matter for the contractor to lay the concrete floor under the pipes hereafter if they are not properly kept up, therefore the firm should be called upon to raise them at once to the height specified.

No. 46.

Messrs. Hudson Bros. to The Engineer-in-Chief.

Sir, Redfern Works, Sydney, 31 October, 1885.

I have the honor to report that our contract for the temporary water supply is completed, with the exception of twenty-four pipes (about 450 feet) to be laid between Ettinger's and Pott's Hill, and the laying of the pipes across the Nepean and Menangle Creeks.

You

You will remember that we have made 1,200 feet of 30-inch pipes for the Duck River section, and between 500 and 600 feet of 36-inch pipes for the Nepean and Menangle Creeks, in addition to the work that we contracted to have completed to date, so that we may fairly claim that we have not exceeded our contract time.

I have the honor to inform you that the twenty-four pipes in the Duck River section will be laid on Monday, November 2nd, and the whole of the work, from the canal at Sherwood Heights to Botany, will then be completed.

I expect the pipes will be laid across the Menangle and Nepean Creeks by Saturday, November 7th. I have this day inspected the work across the various creeks above Campbelltown, and have the honor to report that the water has been through the pipes crossing Simpson's Creek, Elladale Creek, and Ousdale Creek. The water was turned off on Friday, October 30th, to enable us to fix the screen, recently ordered by you, in the canal at Simpson's Creek. That work was completed to-day, and the water again turned on to scour the canal between Ousdale and Mullaly's Creek; and I have every confidence that the pipes will be laid across the Nepean and Menangle Creeks by the time the canal is scoured up to them.

I have, &c.,
HENRY HUDSON.

Dated 3rd September, 1885.

KNOW all men by these presents that Hudson Brothers (Limited) of Sydney in the Colony of New South Wales a Company registered under the provisions of the Companies Act John Woods of Manly in the Colony aforesaid Esquire and James Carnagie Alexander of Sydney aforesaid Esquire are jointly and severally held and firmly bound unto Her Most Gracious Majesty Queen Victoria in the penal sum of six thousand pounds sterling to be paid to Her said Majesty her heirs or successors for which payment well and truly to be made Hudson Brothers (Limited) aforesaid binds itself and its assigns and we the said John Woods and James Carnagie Alexander binds ourselves and each of us and each and every of our heirs executors and administrators jointly and severally firmly by these presents In witness whereof Hudson Brothers (Limited) aforesaid hath caused its common seal to be affixed hereto and the said John Woods and James Carnagie Alexander have hereunto set their hands and seals this third day of September in the year of our Lord one thousand eight hundred and eighty-five Whereas Hudson Brothers (Limited) aforesaid have agreed with the Honorable the Minister for Works acting on behalf of the Government of the said Colony

Colony to find and provide all the materials tools plant labour and every other thing requisite and necessary for and to do and perform the various works required in and about the full and proper construction erection and completion of the works required for bringing in a supply of water from the Nepean and Cataract Rivers in the said Colony as a temporary water supply for Sydney and delivering the same into No. 6 or No. 4 dam near Sydney at or about the part where the Gardener's Road intersects it according to the specification hereto annexed marked A the tender or letter of Hudson Brothers (Limited) of date 4th June last hereto annexed marked B and the letter of Hudson Brothers (Limited) of date 13th July last hereto annexed and marked C and under and in accordance with the general conditions hereto annexed and marked D at or for the price or sum of sixty-five thousand pounds mentioned in the said tender or letter of date 4th June it being understood and agreed between Hudson Brothers (Limited) and the Secretary of Works on behalf of the Government of the said Colony that the works to be done by Hudson Brothers (Limited) are those set out and mentioned in the said specification and the said two several letters or any one of them that is to say the whole of the works mentioned in the specification though some or some portion thereof is not included or referred to in either of the said letters and the whole of the works mentioned and referred to in the said letters or either of them although the same or some portion thereof is not mentioned in the said specification and also under and in accordance with the said general conditions hereunto annexed and are marked D at or for the said sum of sixty-five thousand pounds And that Hudson Brothers (Limited) shall complete and perfect the whole of the said works on or before the thirty-first day of October one thousand eight hundred and eighty-five And whereas the Secretary of Works on behalf of the Government of the said Colony agreed with Hudson Brothers (Limited) as aforesaid upon condition also that Hudson Brothers (Limited) with two sufficient sureties should enter into a bond to Her Majesty in the penal sum of six thousand pounds conditional to secure the due completion of the said works and the proper carrying out of the said contract and the above-bounden John Woods and James Carnagie Alexander have severally offered to become and be bound to Her Majesty her heirs and successors as such sureties for the due performance and completion of the said works within the time hereinbefore mentioned in that behalf and according to terms and conditions of the said specification and the said two several letters and under the said general conditions Now the condition of the above written bond and obligation is such that if Hudson Brothers (Limited) aforesaid do and shall well and truly provide the materials tools plant labour and every other thing requisite and necessary for and do and shall erect complete and finish the said works in the said specification or in the said letters or either of them mentioned as hereinbefore is stated in accordance in all things with the terms and conditions of the said specification and the said two several letters and under and in accordance with the said general conditions and within the time in that behalf hereinbefore mentioned then this obligation will be void and of non-effect otherwise to remain in full force and virtue.

The Common Seal of Hudson Brothers (Limited) aforesaid was affixed hereto at a meeting of the Board of Directors of the said Company by HENRY HUDSON Managing Director FRED. THOS. HUMPHERY SAM. W. GRAY Directors of the said Company in the presence of— JOHN PORTUS. (L.S.)

Signed sealed and delivered by the said JOHN WOODS in the presence of— JOHN PORTUS. JOHN WOODS.

Signed sealed and delivered the said JAMES CARNAGIE ALEXANDER in the presence of— JOHN PORTUS. JAMES C. ALEXANDER.

No. 51.

Specification of Temporary Water Supply.

A.

DESCRIPTION of work to be done in connection with bringing a supply of water from the Nepean and Cataract Rivers, and delivering the same in No. 6 dam, at or about the point where the Gardener's Road intersects it.

ABOVE PROSPECT RESERVOIR.

THE work to be done above Prospect Reservoir consists in lying 36-inch pipes across nine openings, viz. :— Eight across creeks known as Simpson's, Elladale, Ousdale, Mullaly, Leaf's, Nepean, Woodhouse's, and Menangle, and one over the railway cutting between Campbelltown and Menangle.

The 36-inch pipes for this work will be found by the Government, and delivered in sufficient numbers on either bank of each of the crossings. The contractor must then take delivery, and lay them across from the finished portion of the canal on one side to the finished portion on the other side; but the Government shall not be held responsible for any delay in the delivery of the pipes.

The contractor will be held responsible for the safety of all the pipes after they are delivered on the ground, and must, at his own expense, replace any that may become broken in any way.

The pipes shall be laid a short distance down the centre of the canal, and turned out through a cutting to be made by the contractor, and be carried as shown on plans either above or below the canal line, and parallel with it, but clear of works that may be necessary to be hereafter constructed in connection with the erection of the permanent tubes. When the pipes are laid, suitable dams of concrete or brick shall be constructed in an approved manner on the upper side across the finished portion of the canal, so as to raise the water and give it a sufficient head to pass through the pipes; a similar dam shall be constructed across the canal at the outlet end of the pipe to retain the water.

The contractor shall perform all excavation, whether in earth or rock, necessary for passing the 36-inch pipes out of the canal and across the several gullies, &c., the cost of all such excavation being included in the contract lump sum.

The

The pipes may be laid as an inverted syphon down the slopes, but must in all cases be carried on timber trestles well above flood-level. So long as the pipes are clear of flood-level the contractor may elect what height he finds most convenient to construct the timber trestle-work, but it must be understood that should any bends be required other than the two at each end necessary for leading the pipe out of the canal all such extra bends must be supplied and paid for by the contractor.

The pipes crossing over the railway beyond Campbelltown shall be carried on a level from abutment to abutment; and for this purpose a substantial timber trestle bridge must be constructed in accordance with the special design prepared for the work, which provides for the pipes being laid in a manner that will not interfere with the erection of the permanent aqueduct pipes hereafter.

The posts or uprights must be Oregon pine 12 × 12, properly framed in sills, with headstocks and all necessary bracing complete.

Corbels and girders, 12 × 12, shall be laid across and properly secured to span the openings. The supports must be erected to clear the railway as well as to be clear of the site of the piers for the permanent aqueduct.

The 8-feet openings in the abutment through which the 36-inch pipes are to pass must be closed up with T and G pine planks, 3 inches thick, securely bolted to the flanges and sufficiently braced and stiffened to make the ends strong and watertight.

The pipes must be cleaned out and properly jointed in a suitable manner; but, so long as the work is substantially done and the joints are made watertight under the full pressure, lead need not necessarily be used, as caulking with Europe strands or with sawn wood wedges, or both combined, will probably be found sufficient.

At the above and all other railway crossings where the flumes, pipes, or other works cross or lie near to or within railway premises the contractor must obtain permission of the Commissioner for Railways or his properly authorized officer to enter upon the same, before interfering with any works or land connected with the railways, and at all times he shall carry out any instructions he is given with a view to the safe working of the railways.

The contractor will be held wholly responsible for any accident or delay that may occur to the railways through the execution of the works in connection with the Temporary Water Supply.

The works below Prospect consist in the construction of open fluming from the present canal end, viz., from 4 miles 4,000 feet to a point known as Ettinger's, at 6 miles 3,000 feet below Prospect, a distance of 1 mile and 4,280 feet, crossing the Great Southern Railway on its way.

From Ettinger's to Potts' Hill, viz., 6 miles 3,000 feet, to 9 miles 3,500 feet, a distance of about 3 miles 500 feet, an inverted syphon pipe, 30 inches internal diameter, must be constructed and laid, except for a distance of about 1,200 feet along the lowest portion of the valley where the pipe line crosses the Duck Creek. For this portion of the line 36-inch pipes will be supplied and delivered by the Government, and must be laid and jointed as before specified.

From Potts' Hill to No. 6 dam at Botany, wrought iron pipes not less than 20 inches internal diameter must be constructed and laid—the length of the pipes being about 12 miles.

Flumes:—The flumes between 4 miles 4,000 feet and 6 miles 3,000 feet will be constructed on trestle-work, in accordance with the general design prepared for the work. The waterway shall be formed of galvanized corrugated sheet iron of 26 gauge, riveted together, and curved to a segment of a circle, providing a water-way 5 feet wide and 2 feet deep, and laid throughout the whole distance with a falling gradient of 6 inches to a mile.

The riveting of the sheets together must be done in a workmanlike manner so as to make them perfectly water-tight. The seams shall then be payed over with hot asphalt composition, or otherwise treated to make them water-tight.

Where the flume commences it must be connected in an approved manner with the waterway of the canal, so that it will not interfere with the carrying on to completion of the permanent pipe head basin. For this purpose the flumes will have to start from one side of the canal, at such distance back as the state of the works on Contract No. 21 may necessitate, and a suitable dam constructed across the canal to raise and direct the water into the flume.

Special care must be taken to ensure the stability of the trestle-work, &c., at the crossing of the Great Southern Railway, as before mentioned. This work must be carried out in such a manner as may be approved of by the railway authorities.

Pipe-head Tank.—A suitable receiving-tank must be constructed at the end of the flume to form a pipe-head. This tank should be about 10 or 12 feet square, constructed of timber, with its sides up to the level of the top of the flume, and the bottom should be at least 4 feet below the bottom of the pipe-outlet, so as to form a trap to arrest stones or other obstructions from passing into the pipe. A suitable 9-inch wash-out pipe and valve must lead from the bottom of the tank to drain off the water and clean the tank where necessary, and a proper escape for the water must be provided.

30-*inch Pipe*.—This pipe shall be constructed of sheet-iron, with properly riveted seams; the thickness of the iron may vary in proportion with the head on the pipe at the higher levels. It may be No. 16 gauge, increasing to No. 11 gauge at the lowest levels, where the maximum pressure will be about 50 lbs per square inch.

The curving, jointing, and riveting must be carefully carried out to ensure a perfectly watertight pipe.

Air-valves.—On the summit of all rises, no matter how small, suitable air-valves or air-cocks must be provided and fixed to allow for the escape of the air when filling the pipes, and to enable the air which will collect in the pipe being drawn off from time to time.

Sludge-valve.—At the bottom of the syphon near Duck Creek a 9-inch branch scour-pipe and valve must be provided and fixed for scouring out the pipe from time to time.

Balance Tank.—On Potts' Hill, where the 30-inch pipe ends, another tank about 8 feet × 8 feet must be constructed, to form a balance-head for the 20-inch pipe. The sides of this tank must be carried up to R.L. 171·00, being the level of the surface of the water at the end of the open flume.

36-*inch Pipe*.—As before mentioned, the Government will provide and deliver about 1,200 feet of 36-inch pipes across the depression through which the Duck River flows, which the contractor must lay and joint as before specified. Suitable diminishing pieces must be provided by the contractor to connect the 30-inch and 36-inch pipes at each end, the whole being jointed up and made perfectly water-tight in a workmanlike manner.

Bridge

Bridge over Duck River.—A suitable trestle bridge must be constructed across Duck River to safely carry the 36-inch pipes above flood-level in the creek.

Crossing Roads.—Where the 30-inch and 36-inch pipe lines cross the roads the pipes must be buried sufficiently deep to allow at least 2½ feet cover over the top of the pipe. Along other portions of the line from Ettinger's to Potts' Hill the pipes may be laid on the surface of the ground. Suitable crossings must however be provided where necessary for crossing traffic over the pipes, either by burying them as above specified or by enclosing them within a timber case and raising approaches on either side.

20-inch Pipe.—From Potts' Hill to No. 6 dam at Botany the water will be conveyed through riveted wrought-iron pipes of not less than 20 inches diameter. These pipes will commence at the balance tank on Potts' Hill previously referred to, and shall follow the land resumed for the permanent pipe line as far as the Liverpool Road, thence keeping on or near that road as far as its junction with Milton-street, Ashfield. The pipes will then lead along the following streets, viz.:—Milton-street, Arthur-street, Victoria-street, Robert-street, Prospect Road, William-street, Henson-street, James-street, across Old Canterbury Road, and thence *via* Gamline Road, New Canterbury Road, Marrickville Road, Unwin's Bridge Road, Boundary Line, Cook's River Road, and finally reaching the Gardener's Road shall follow it to the No. 6 Dam.

This route may however be varied if found necessary to obtain better or sufficient gradients.

The 20-inch pipe may be formed with 16 gauge sheet-iron, single riveted throughout, the rivets being about ¾-inch pitch, or closer if found necessary, to secure a perfectly water-tight pipe. It shall be put together stove-pipe fashion, and securely riveted. All seams to be payed over with hot asphalt composition of approved quality.

From Potts' Hill to the Liverpool Road the pipe may be laid along the surface, but passing under all roads as before specified for the 30-inch pipes, and all necessary accommodation crossings shall be provided in an approved manner.

From the Liverpool Road to Botany the pipe shall be wholly buried below the surface, with at least 18-inch cover; but where the line crosses a branch road it must have at least 2½ feet cover, to protect the crown of the pipe from crushing in. If found necessary, the contractor must lay sleepers and a plank covering over the pipes to protect them from wheel traffic.

When the contractor breaks up the surface of roads to lay the pipe he must make good the formation again to the approval of the authorities in charge of the various roads affected, and maintain the roadway immediately over the pipe trenches in good order for a period of six (6) months from the date of completion of the laying of the pipes.

Drainage.—Care must be taken in laying the pipes that the work shall be done in such a manner as not to interfere with the natural drainage passing along or under the roads. Where the line crosses creeks, such as Bark Huts, Long Cove, Halligan's, or Shea's Creeks, sufficient staying or supports must be erected to carry the pipe safely across over flood-level.

Air-valves.—Suitable air-valves shall be inserted in the pipe at the crown of all summits along the whole length of the pipe line, to permit of the free discharge of the air. These valves shall be in all cases covered over with suitable surface-boxes, so as to be at all times readily accessible.

Sludge-valves.—At least three 9-inch branch pipes fitted with approved valves shall be provided and fixed to the pipes, in depressions at points to be hereafter decided upon, for the purpose of cleaning out the pipes from time to time.

The contractor will be held wholly responsible for all claims that may be made for injury to adjacent properties during the execution of these works; and when the pipe is laid along or across streets or roads, the authorities, municipal or other, in charge of the said roads or streets, must be notified thereof by the contractor, who shall carry out all repairs and maintenance to their satisfaction, and the contractor shall carry out the works in the various Municipalities, as regards lights, hoardings, &c., necessary for protection of life and prevention of accidents, in strict accordance with the by-laws of each Municipality or directions of the proper officers.

The work shall be carried throughout in a substantial manner, to the satisfaction of the Engineer-in-Chief for Harbours and Rivers.

Notwithstanding the specification herein of anything to the contrary, the dimensions and gradients at all parts must be made sufficient to deliver the minimum quantity of 3,000,000 gallons per day into the Botany dams, the contractor being wholly responsible in this respect.

The Government reserves the right to cancel the contract at any time by giving notice to that effect in writing; and such compensation as may be mutually agreed upon between the Engineer-in-Chief and the contractor, will be forthwith paid to the contractor; but failing a satisfactory settlement as to the compensation to be allowed, the matter shall be decided by arbitration, each party to the contract naming an arbitrator and binding themselves to abide by the award; but should the two arbitrators so appointed fail to agree, they shall mutually appoint an umpire, whose decision shall be final and binding upon all parties concerned.

It shall be distinctly understood that the contractor shall be wholly responsible for the efficient carrying out of this contract, that is to say, if it is found necessary by the Engineer-in-Chief during the progress of the works, to substitute material and labour of a higher and more expensive class than is herein specified, such labour and material shall be supplied by the contractor, for which he shall have no extra claim.

It being also to be understood that any deviation from the contract which shall be judged advisable by the Engineer-in-Chief shall be carried out, and shall not on any pretence entitle the contractor to any extra payment, the lump sum of £65,000 being held to include any and every such deviation or alteration in the work.

The Engineer-in-Chief shall also have full power to direct the order in which the various parts of the work shall be carried out, and shall, if he see fit, order the stoppage for a time of any or all parts of the work, without prejudice to this contract, or giving the contractor a claim for demurrage. And in the event of such stoppage, the contractor shall only be entitled to an extension of time equivalent to the duration of such stoppage or stoppages.

In the event of any exceptionally bad weather, the Engineer-in-Chief at his discretion shall have power to grant such extension of time as he may think just and fair under the circumstances, and from his decision in this respect there shall be no appeal.

It shall be understood that the General Conditions attached hereto shall only hold good so far as they are not repugnant to the terms of this specification.

As the work comprised in this contract has been let under exceptional circumstances to Messrs. Hudson Brothers (Limited), and upon a written undertaking given by them previously to this specification having been prepared, and in the absence of the usual detailed plans, surveys, &c., it is distinctly to be understood it is not pretended that herein is specified every detail of the work to be performed. Everything necessary however for the accomplishment of the required result in a substantial and workmanlike manner to the satisfaction of the Engineer-in-Chief for Harbours and Rivers shall be done or supplied whether the same be specified or not; and the contractors shall have no ground of action, either in law or equity, on the plea that any work ordered by the Engineer-in-Chief to be done or material supplied was not included in the specification or intended to be employed by them in the execution of their contract; and in the event of any such work and material being performed or supplied it shall be considered the same as if specifically provided for in this contract, and the cost thereof shall be regarded as included in the contract sum of £65,000, and the execution or supply thereof shall not entitle the contractors to any extra amount over that sum on any pretence whatever.

And the contractors on their part by their signature hereto expressly acknowledge their full liability under these terms after having carefully read and considered the same.

In addition to the fines leviable under this contract in the event of the work not being done within the contract time, the following additional fines shall be imposed on the contractors and be payable to Her Majesty should the works not be found of sufficient capacity to deliver the full quantity of water contracted to be so delivered at the No. 6 dam at Botany (that is to say, 3,000,000 gallons per diem), viz., at the rate of £5,000 for every 500,000 gallons or part thereof which the said works shall deliver short of the stipulated quantity (viz., 3,000,000 gallons in each twenty-four hours) in the said dam at Botany.

The contractors therefore, in view of their liability to this fine, shall have full liberty, if they think it necessary so to do, to increase the delivering capacity of any or all parts of these works. But in the event of their doing so they shall not on that or any account be entitled to claim any extra amount over the contract sum of £65,000; neither shall they be entitled to plead in mitigation, in the event of the full quantity not being deliverable, that the works as specified herein were not capable of delivering the full quantity stipulated, viz., 3,000,000 gallons per diem of twenty-four hours, it being understood that the contractors accept all and every responsibility on this and every other score in connection with this contract.

E. O. MORIARTY.

This is the specification marked "A," referred to in our annexed Bond to Her Majesty the Queen, dated the 3rd day of September, A.D. 1885.

HENRY HUDSON, Managing Director.
FRED THOS. HUMPHERY.
SAMUEL W. GRAY.
JOHN WOODS.
JAMES ALEXANDER.

Witness—JOHN PORTUS.

GENERAL CONDITIONS.

Interpretation clause.

1. The words "Superintending Officer" in these conditions shall mean any person who may from time to time be appointed by the Engineer-in-Chief for Harbours and Rivers to supervise the works or buildings, and the words "Engineer-in-Chief" or "Engineer" shall mean the Engineer-in-Chief for Harbours and Rivers for the time being. The words "Minister for Works" shall mean the Secretary for Works for the time being. The word "Government" (where used) to mean the Government of New South Wales promoting this undertaking. The word "Schedule" to mean the adjusted Schedule of prices settled by the Engineer and contractor previous to commencing the work. Words importing the singular number only shall include the plural number, and words importing the plural number only shall include the singular number.

Dismissal of Workmen, removal of improper materials, &c.

2. The Engineer-in-Chief shall have the power of immediately dismissing any agent or workman employed by the contractor, and of having removed off the works any materials, plant, or implements which in his opinion are insufficient for the purpose intended, or at variance with the meaning and intention of this specification; and the cost of the removal of any such plant, materials, or implements shall be paid by the contractor.

Instructions to be obeyed.

3. Should the contractor refuse or neglect to carry out the instructions of the Engineer or the Superintending Officer, the Engineer shall have the power of suspending the usual monthly certificate until such instructions have been complied with.

Drawings, specifications, &c.

4. The plans, sections, and drawings represent generally the form and dimensions of the several works. Where any discrepancy exists between the dimensions as indicated by the scale and those marked in figures, the figures are to be considered as correct, and are to be taken in all cases in preference to the measurements by the scale attached; and if there should be any discrepancy between the figures or dimensions, or the form of construction, or the material as indicated in the drawings, and the dimensions, form of construction, and materials given in the specifications, the directions of the specification shall be adopted; and in all cases of defective description or any ambiguity, the explanation given by the Engineer shall be binding upon the contractor. Also, anything contained in the drawings and not in the specification, or anything contained in the specification and not shown in the drawings, shall be equally binding as if it were contained in both.

Extra

Extra works, omissions of works, &c.

5. If at any time whilst the works are in hand it shall be deemed expedient by the Engineer to order material or work of a different description to that specified or to increase or diminish the dimensions or extent of any works to be done under this contract, or to alter their situation or to vary the form or dimensions of any of the said works, or of any part thereof, or to substitute one class of work for another, he shall have full power to do so, and to order and direct any such increase, diminution, alteration, or substitution, which shall be executed by the contractor, and if of the class of works provided for in the schedule of prices, at such schedule prices; and no such increase, diminution, alteration, or substitution of works shall in any way annul or set aside this contract, or extend the time for the completion thereof, unless the Minister for Works shall see fit to grant such extension, but such additions or alterations shall be measured and allowed and paid for, or deducted from the contractor's account, as the case may require, according to the schedule of prices. Provided that if any portion of the works so ordered to be done shall not be of the class of works provided for in the schedule of prices, the same shall be executed by the contractor at such prices as may be agreed for with the Engineer-in-Chief; but if the contractor and the Engineer-in-Chief cannot agree as to the price to be paid, the Engineer aforesaid may order and direct the same to be done by such person or persons as he may think fit.

Net measurements.

6. All measurements of the works shall be made according to the actual dimensions, notwithstanding any general or local custom to the contrary.

Labour, materials, plant, &c.

7. The contractor shall provide at his own costs and charges all materials, labour, tools, plant, tackle, machinery, scaffolding, &c., for the proper completion of the works at the prices stated in his schedule or tender.

Contractors liable for injury to adjoining lands, properties, &c.

8. In executing the several works herein specified, or conveying materials thereto, the contractor must be careful to do as little damage or injury to the adjoining lands or properties as possible, and he will be held answerable for the whole amount of such damage or injury, which may be deducted out of the moneys he may have in the hands of the Government.

Contractors to take the whole risk of executing the works properly.

9. The contractor shall take upon himself the whole risk of executing the works to the satisfaction of the Engineer-in-Chief, and in accordance with the plans, sections, and specifications, of the correctness of which he must satisfy himself.

Setting out works.

10. The works will be set out for the contractor, but he must satisfy himself of their accuracy, as no work incorrectly set out or improperly executed will be paid for by the Government.

Contractor to be represented.

11. The contractor at all times during the progress of the works, when he is not personally superintending them, must have a responsible agent or overseer stationed on them to receive instructions from the Superintending Officer or Engineer-in-Chief, and to represent the contractor for all the purposes of this contract.

Progress of works.

12. Should the Engineer be at any time dissatisfied with the mode of proceeding, or at the rate of progress of the works or any part thereof, he shall have full power without vacating this contract to take the works wholly or in part out of the hands of the contractor, and to procure, employ, and make use of all labour or materials which he may deem necessary for completing the works, the cost of such labour and materials to be deducted from any money that may be then due, or may thereafter become due to the contractor; and if the money then due or thereafter becoming due to the contractor shall not be sufficient for that purpose, the balance remaining unpaid may be recovered in an action for damages for breach of contract or as money paid for the use of contractor.

Cancellation of Contract.

13. The Government or the Engineer-in-Chief shall have the option, and full power and authority, in lieu of proceeding under the last preceding clause of these conditions, if the contractor fail to proceed in the execution of, and to carry on the works in the manner and at the rate of progress required by the Engineer, of cancelling this contract so far as relates to the works remaining to be done; and in such case the moneys which shall have been previously paid to the contractor on account of the works executed shall be taken by him as full payment for all works done under the contract; and upon notice in writing under the hand of the Engineer-in-Chief that he, under the authority of this condition, cancels the contract, being served upon the contractor, or left at his last-named place of abode, the contract shall be cancelled; and thereupon all sums of money that may be due or unpaid to the contractor, together with all implements in his possession, and all materials provided by him, upon the ground upon which the work is being carried on, or adjacent thereto, shall be forfeited, and all sums of money named as penalties for the non-fulfilment of the contract within the time specified, shall also be forfeited and become payable to the Government, and the said implements and material shall become and be the absolute property of the Government, and with the moneys so forfeited and payable as aforesaid shall be considered as ascertained damages for breach of contract.

Time of completion, &c.

14. The contractor shall complete the whole of the works comprised in this contract, on or before the thirty-first day of October, one thousand eight hundred and eighty-five, and in the event of their non-completion at the specified time, should the Engineer-in-Chief not have proceeded under clauses Nos. 12 and 13 of these conditions, or either of them, the contractor shall forfeit and pay (£100) one hundred pounds sterling for each day or for every part of a day that shall elapse after such specified time until their completion, and which sum or sums may be deducted from any money payable to the contractor under this or any other contract. No certificate will be given after the date specified in these conditions for the completion of the contract, until the whole of the works shall have been properly completed to

the

the satisfaction of the Engineer-in-Chief, unless the time for the completion of the contract shall have been extended by the Minister for Works, in which case such extended time shall become the time for the completion of the contract, and it is to be expressly understood, that the fact of the time having been so extended shall not in any way be taken as a waiver of the contract, or as annulling or setting aside the contract in any respect, or be taken as releasing the contractor, or his sureties, from any of the responsibilities or obligations of the contract; which, in all other respects, shall remain the same as if the time had not been extended.

The like liability also shall hold good as to the obligations of contractor and sureties in the event of any advance to the contractor being made for the retention money, or on material on the ground and not *in situ*, and for the purposes of this contract it shall not be necessary to apprise the sureties of any extensions of time having been granted, or advances and payments made, as contemplated in this or other clause or clauses of these general conditions or of the specification.

Copies of drawings, &c.

15. All copies of drawings or specifications required by the contractor for carrying on the works must be made at his expense, but should any copies of drawings or specifications be furnished to him at the expense of the Government, they must be returned to this office before a final certificate for the work shall be given.

Liability of Contractor.

16. The care of maintenance of all works under this contract shall remain with the contractor until their completion, and until the Engineer-in-Chief for Harbours and Rivers shall, by notice in writing under his hand, inform the contractor that he has taken charge thereof; and until such notice shall have been given, the contractor shall be responsible for all accidents from whatever cause arising, and shall make good all damage thereto.

Contractor not to sub-let works or assign moneys.

17. The contractor shall not assign over or under-let this contract or any part thereof, or assign all or any of the moneys payable or to become payable under the contract, or all or any part thereof, or any other benefit whatsoever arising, or which may arise under this contract, to any other person, without the consent in writing of the Engineer-in-Chief for Harbours and Rivers first obtained. The contractor, for each and every breach of this condition shall pay to the Government the sum of £50 as and for liquidated damages; and the sum or sums payable as such damages may be deducted from any sum or sums due to the contractor under this or any contract with the Government. And any permission to assign over or underlet works to be done under this contract shall not discharge the contractor from liability to see that the works so assigned or under-let are executed and completed in terms of this contract.

Truck system not allowed.

18. The workmen, tradesmen, and labourers of every class employed on the works to which these conditions refer, shall be paid their wages, in full, in money, current coin of the Colony, at least once in every month, and no ticket or other system of payment by provisions, liquors, or goods, will on any pretence be allowed; nor shall the contractor, or any person or persons employed by him, or in any way connected with him, establish any shop for the supply of provisions, liquors, or goods; nor shall the contractor oblige his workmen to take provisions, liquors, or goods of any kind from any person in particular. The workmen of every class shall be paid on the works if it be possible, or in some building adjoining; and in no case shall they be paid at a public-house or other place where liquors or refreshments are sold.

Power to the Government to pay Workmen's wages.

19. Before the payment of any money to the contractor, the Engineer-in-Chief may require from him a statutory declaration that the tradesman and labourers of every kind employed on the works to which these conditions refer have been paid their wages and claims of every kind in full, in money, the current coin of the Colony, and to the latest date at which such wages or claims are due; and the Engineer-in-Chief may withhold the payment of any money that may be due or may become due to the contractor, until such declaration has been made and delivered to him.

If the contractor shall fail or omit to pay the wages of any workmen employed upon the works, in the current coin of the Colony, it shall be lawful for the Government, or the Engineer-in-Chief, as often as the same shall happen, upon complaint of such failure or omission made by any such workman, and upon production or other satisfactory proof of any judgment or order of a Court of Petty Sessions, or of any other Court of competent jurisdiction, to pay the amount mentioned in such order to such workman, and to deduct the same amount from any money then due or owing, or thereafter to become due or owing, to the contractor, under this contract.

Bankruptcy or Insolvency.

20. If the contractor shall become insolvent, have his estate placed under sequestration, or shall make an assignment of his estate for the benefit of his creditors, it shall be lawful for the Government without previous notice to the contractor, or to the official or other assignee or assignees of his insolvent estate, or to the trustee or trustees under the assignment, to take the works out of the hands of the contractor and of the assignees or trustees of his estate, and to recontract with any other person or persons to proceed with and complete the same, upon such terms, stipulations, and conditions as shall be deemed expedient; and all the then remaining materials, implements, and plant aforesaid may be used in and applied for the purposes of the works; but on the final completion of the works, the surplus of such materials, implements, and plant shall cease to belong to the Government and shall become the property of the said assignees or trustees, without any allowance for or payment by the Government, or on account of any loss or diminution, wear, tear, or injury they may have sustained in the meantime.

Security.

21. The contractor will be required to provide two approved persons as sureties, to enter with him into a bond to the Government jointly and severally, in the penal sum of six hundred pounds for the proper performance and completion of the contract; the names of the persons proposed by him as sureties must be stated in his tender, the Government reserving to itself the power of rejecting such proposed sureties should it deem it advisable to do so.

Should

Should the contractor fail to procure such persons as may be deemed by the Government to be eligible sureties, within six days from the acceptance of the tender, or should the contractor fail to execute the contract for the due performance of the works mentioned in the said tender, or to execute and procure the due execution by the persons so approved of as sureties of the bond required hereunder for securing the due completion of the works to be done under the said contract within fourteen days after the acceptance of such persons as sureties has been notified to him, the Government will have the option of and full power and authority to declare such acceptance to be annulled.

No tenderer will be allowed to proceed with the work tendered for until he has provided approved sureties, has executed the required contract, and has, with such sureties, duly executed the bond before mentioned for the due performance of the said contract—it being hereby declared that for all or any work done or materials found and provided by the contractor before the due execution of the said contract and bond, he shall not have any right of action, claim, or demand against the Government.

Progress payment without prejudice, &c.

22. No certificate given to the contractor for the purpose of any progress payment shall prevent the Engineer-in-Chief from, at any future time before the termination of the contract, rejecting all unsound materials and improper workmanship discovered subsequently to the giving of the last previous certificate; and notwithstanding the giving of any certificate that portions or the whole of the works have been satisfactorily performed, the Engineer-in-Chief may require the contractor to remove and amend at any future time previously to the final payment on account of the construction or maintenance of the works, any work that may be found not to have been performed in accordance with the contract; and the contractor must remove and amend at his own cost all such work when so required, notwithstanding any approval made or given by the Superintending Officer; and the Government shall have power, on the report of the Engineer-in-Chief that the work approved of as aforesaid is not in accordance with the contract, to deduct from any moneys that may be due or that may become due to the contractor, the whole amount that has been paid on account of the work.

If, in the opinion of the Engineer-in-Chief, further inquiry is necessary or desirable before any certificate is given, he shall have power to withhold such certificate for any period which he may consider necessary for the purposes of such inquiry, from the date at which in the ordinary course the certificate would have been given.

None of the conditions of this contract shall be varied, waived, discharged, or released, either in law or in equity, unless by the express consent of the Government, testified in writing.

Payments.

23. Payments may be made once in every month, unless the same shall become not payable by reason of anything contained in these conditions, up to the date specified for the completion of the contract, on the Engineer's certificate as the work proceeds, in the proportion of 75 per cent. of the value of the work satisfactorily executed, and the remaining 25 per cent. will be paid after the Engineer has certified that the whole of the works have been completed to his entire satisfaction, and that the period specified for the maintenance of the said works has expired; and it is expressly declared that the obtaining a certificate from the Engineer that the work done by the contractor has been satisfactorily executed or completed to his satisfaction shall be a condition precedent to the contractor having any right or cause of action in respect of any work done or material provided, and to the contractor having any right of action or claim to the payments from time to time to be made hereunder, as well as to the final payment upon the whole of the work being finished.

Maintenance.

24. The contractor will be bound to maintain the works for a period of six months after their final completion and use; and if any part should, within that period show signs of weakness or of giving way, or should any defective workmanship or materials be detected, the contractor when called upon to do so shall make good the same at his own cost, to the satisfaction of the Engineer-in-Chief, before the reserve balance will be paid.

No. 53.

Messrs. Hudson Brothers to The Engineer-in-Chief.

Sir,

Redfern Works, Sydney, 26 November, 1885.

I have the honor to inform you that we experience most unexpected difficulties in making the joints of our pipes tight enough to withstand the great pressure exerted upon them at Duck Creek depression. We have been battling with this difficulty for over a week now, and have not yet succeeded in overcoming it, but are confident of being able to do so ultimately.

We were in hopes we should have been able to stop the leaks without turning the water off, but think we had better ask you to do so now, as we think we shall be able to get over the difficulty sooner.

This will also necessitate us asking for an extension of time, which I feel sure you will recommend, as when we made the offer to bring the water into Sydney we stipulated for cast iron pipes to be used in this length of the work, and the pipes to be supplied by the Government. After our offer was accepted it was found the Government could not procure the cast iron pipes, and we undertook to make them of sheet iron, without any additional charge; so now we trust you will recommend an extension of time be granted to us to make good the defects that have occurred in carrying out the scheme.

I have, &c.,

(For Hudson Bros., Limited),
HENRY HUDSON,
Managing Director.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

TEMPORARY WATER SUPPLY FOR SYDNEY.

(FURTHER PAPERS.)

Ordered by the Legislative Assembly to be printed, 27 November, 1885.

Mr. H. Hudson to The Engineer-in-Chief for Harbours and Rivers.

Redfern Works, Sydney, 27 November, 1885.

Sir,

My attention has just been drawn to the report of the papers laid on the Table of the House in connection with the Temporary Water Supply, and I notice that special comment has been made on Mr. Grimshaw's letter. I would ask, in common justice to us, that you will acknowledge that we rectified every defect in that portion of the work, and that the whole of the works, from Simpson's Creek (the first creek we had to bridge) right through to Ettinger's, has been an absolute success.

You will remember that the cause of the lead coming out of the joints on this portion of the work was through the great expansion and contraction on the long length of pipes; but since the water has been turned into these pipes the leakage has entirely stopped.

I have, &c.,
HENRY HUDSON.

Memo. by Engineer-in-Chief for Harbours and Rivers.

(Forwarded for the information of Mr. Secretary Lyne.)

MR. HUDSON asks me to acknowledge that his firm have rectified every defect in the portion of the work for the Temporary Water Supply to which my attention was drawn in Mr. Grimshaw's letter of the 1st October. I have much pleasure in being enabled to state that such has been the case.

It is right I should add that I have, on every occasion, found the Messrs. Hudson anxious to meet my requirements and do all in their power to make the work a success.

They have, no doubt, had difficulties to encounter; but, with energy, skill, and perseverance, they will be satisfactorily overcome.

E. O. MORIARTY.

B.C., Under Secretary, Public Works.

NEW SOUTH WALES.

LANDS FOR PUBLIC PURPOSES ACQUISITION ACT.

(RESUMPTION FOR WATER SUPPLY, HUNTER RIVER DISTRICT.)

Presented to Parliament, pursuant to Act 44 Vic. No. 16, sec. 6.

NOTIFICATION OF RESUMPTION OF LAND UNDER 44 VICTORIA, No. 16.

NEW SOUTH WALES, to wit. } By His Excellency The Right Honorable Sir AUGUSTUS WILLIAM FREDERICK SPENCER LOFTUS (commonly called Lord AUGUSTUS LOFTUS), Knight Grand Cross of the Most Honorable Order of the Bath, a Member of Her Majesty's Most Honorable Privy Council, Governor and Commander-in-Chief of the Colony of New South Wales and its Dependencies.

(L.S.)
AUGUSTUS LOFTUS, *Governor.*

WHEREAS I, the Governor aforesaid, with the advice of the Executive Council of the said Colony, have duly sanctioned the carrying out of certain works for and in connection with the supply of water to the City of Newcastle, and the towns of Maitland, Morpeth, and the mining townships situated in the Hunter River District, in the said Colony, for and towards the completion of which said works public funds are available under the provisions of the "Appropriation Act of 1879;" and whereas the lands hereinafter described are required for the construction of the said works: Now, I, the Governor of the said Colony, with the advice of the Executive Council of the said Colony, in pursuance of the powers in this behalf given to or vested in me by the "Lands for Public Purposes Acquisition Act," do by this notification, published in the Gazette and in a newspaper, that is to say, in the "Maitland Mercury," circulated in the Police District wherein the said lands are situated, declare that the lands hereinafter described have been resumed for the public purposes hereinafter mentioned that is to say, for and in connection with the supply of water to the said City of Newcastle, and the towns of Maitland, Morpeth, and the mining townships situated in the Hunter River District, to the intent that, upon the publication of this notification in the Gazette, the legal estate in the said lands shall forthwith be vested in the Minister for Public Works and his successors, on behalf of Her Majesty, for the purpose of the said last-mentioned Act, for an estate of inheritance in fee simple in possession freed and discharged from all trusts, obligations, estate, interest, contracts, charges, rates, rights-of-way, or other easements whatsoever; and to the intent, further, that the legal estate therein, together with all powers incident thereto or conferred by the said Act, shall be vested in the said Minister as a trustee, with the powers stated in the said last-mentioned Act. And I declare that the following are the descriptions of the lands hereinbefore referred to, that is to say:—

1st. All that piece or parcel of land situated in the parish of Hexham, county of Northumberland, and Colony of New South Wales, being part of a grant of 1,280 acres, to Mrs. C. Brookes: Commencing at a point on the southern boundary of land already resumed for the purposes of the Hunter River District water supply, bearing south 26 degrees east 73 chains 67½ links from the north-west corner of the said 1,280 acres; and bounded thence by said southern boundary bearing south 20 degrees 13 minutes east 50 links; thence by a line bearing south 69 degrees 47 minutes west 26½ links; thence by 3 chains 59 links of a concave curve of 5 chains 81·06 links radius, the chord of which bears south 52 degrees 5 minutes west 3 chains 53½ links; thence by a line bearing south 34 degrees 23 minutes west 4 chains 64¼ links; thence by a line bearing south 55 degrees 37 minutes east 1 chain 26½ links; thence by a line bearing south 34 degrees 23 minutes west 2 chains 92 links; thence by a line bearing south 88 degrees 56 minutes west 3 chains 72½ links; thence by a line bearing north 34 degrees 23 minutes east 5 chains 8 links; thence by a line bearing south 55 degrees 37 minutes east 1 chain 26½ links; thence by a line bearing north 34 degrees 23 minutes east 4 chains 64¼ links; thence by 3 chains 90 links of a convex curve of 6 chains 31·06 links radius, the chord of which bears north 52 degrees 5 minutes east 3 chains 83¾ links; thence by a line bearing north 69 degrees 47 minutes east 26½ links to the point of commencement, containing 1 acre 2 roods 23 perches or thereabouts, and said to be in the possession and occupation of J. W. Brooks.

2nd. All that piece or parcel of land situated in the parish of Newcastle, county of Northumberland, and Colony of New South Wales, being part of a grant of 950 acres to James Mitchell, being also lots Nos. 54, 55, and 56, section 11, of a subdivision of part of the said grant called Burwood township: Commencing on the eastern side of the Lake Road at the south-western corner of lot No. 53 (which corner bears south 48 degrees 7 minutes west, and is distant 24 chains 86 links from Trigonometrical Station B); and bounded thence on the north by lot No. 53 bearing south-easterly 109 feet; thence on the east by lots Nos. 81, 80, and 79 bearing south-westerly 150 feet; thence on the south by lot No. 57 bearing north-westerly 109 feet to the eastern side of the Lake Road; thence on the west by that road bearing north-easterly 150 feet, to the point of commencement,—containing 1 rood 20 perches or thereabouts, and said to be in the possession and occupation of E. C. Merewether.

In witness whereof, I have hereunto set my Hand, and caused the Great Seal of the Colony to be hereto affixed, at Government House, Sydney, this twenty-ninth day of October, in the year of our Lord one thousand eight hundred and eighty-five, and in the forty-ninth year of Her Majesty's Reign.

By His Excellency's Command,
HENRY S. BADGERY.

GOD SAVE THE QUEEN!

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

BORING FOR WATER BETWEEN BOURKE AND WANAARING.

(COST OF, AND QUANTITY AND QUALITY OF WATER IN EACH BORE.)

Ordered by the Legislative Assembly to be printed, 1 *April*, 1886.

THURSDAY, 1 APRIL, 1886.

Question No. 4:—Mr. Wilkinson to ask the Secretary for Mines,—What is the total cost for boring between Bourke and Wanaaring since commencement in 1882, what length of road is watered by the bores, and what is the quality and quantity of water in each bore?

Answer:—Cost of boring, £3,889 14s. Fresh water has been obtained at 51 miles and 57 miles from Bourke, and a bore is now over 400 feet down at 75 miles from Bourke, but no fresh water yet. When this bore is finished, and another between the Kulkine Tank and Wanaaring, the boring on this line will be complete. It is proposed to complete the watering of the road by tanks and dams. The depths of the several bores and the quantity and quality of the water is given in the paper annexed.

BORES, Bourke to Wanaaring.

No. of Bore.	Quality of Water.	Quantity in gallons per day.	Remarks.
A, 18-mile post.....	Salt	9,200	Six tappings, viz., at 22 ft., 60 ft., 64 ft. 6 in., 66 ft., 69 ft., and 72 ft. below surface; depth of bore, 194 ft. 4 in.
B, 51 ,, ...	Fresh	1,000	Rose 8 ft. over surface; four tappings, viz., at 30 ft., 61 ft., 70 ft., and 89 ft. below surface; depth of bore, 89 ft. 2 in.

1885–6.

NEW SOUTH WALES.

LANDS FOR PUBLIC PURPOSES ACQUISITION ACT.

(NOTIFICATION OF RESUMPTION OF LAND FOR SEWERAGE PURPOSES.)

Presented to Parliament, pursuant to Act 44 Vic. No. 16, sec. 6.

NOTIFICATION OF RESUMPTION OF LAND UNDER 44 VICTORIA No. 16.

NEW SOUTH WALES, to wit. } By His Excellency The Right Honourable CHARLES ROBERT, BARON CARRINGTON, a Member of Her Majesty's Most Honourable Privy Council, Knight Grand Cross of the Most Distinguished Order of Saint Michael and Saint George, Governor and Commander-in-Chief of the Colony of New South Wales and its Dependencies.

(L.S.) CARRINGTON, *Governor.*

WHEREAS I, the Governor aforesaid, with the advice of the Executive Council of the said Colony, have duly sanctioned the carrying out of certain works for and in connection with the sewerage of the City of Sydney and its suburbs in the said Colony, for and towards the completion of which said works public funds are available under the provisions of the Act 48 Victoria No. 27, "Appropriation Act of 1885;" and whereas the lands hereinafter described are required for the construction of the said works: Now, I, the Governor of the said Colony, with the advice of the Executive Council of the said Colony, in pursuance of the powers in this behalf given to or vested in me by the "Lands for Public Purposes Acquisition Act," do by this notification published in the Gazette and in a newspaper, that is to say, in the "Sydney Morning Herald," circulated in the Police District wherein the said lands are situated, declare that the land hereinafter described has been resumed for the public purposes hereinafter mentioned, that is to say, for and in connection with the sewerage of the said City of Sydney and its suburbs, to the intent that, upon the publication of this notification in the Gazette, the legal estate in the said lands shall forthwith be vested in the Minister for Public Works and his successors, on behalf of Her Majesty, for the purpose of the said last-mentioned Act, for an estate of inheritance in fee simple in possession, freed and discharged from all trusts, obligations, estate, interests, contracts, charges, rates, rights-of-way, or other easements whatsoever; and to the intent further that the legal estate therein, together with all powers incident thereto or conferred by the said Act, shall be vested in the said Minister as a trustee with the powers stated in the said last-mentioned Act: And I declare that the following is the description of the lands hereinbefore referred to, that is to say:—

1st.—All that piece or parcel of land containing by admeasurement three roods six perches, situate in the parish of Alexandria, county of Cumberland, and Colony of New South Wales, and being a part of the estate known as the Barcom Glen Estate: Commencing at a point on the south-western side of Liverpool-street, distant south-easterly 102·2 links from the south-easternmost intersection of Liverpool-street and Great Barcom-street; thence running south-easterly by a line bearing 140 degrees 22 minutes 45 seconds along the south-western boundary of Liverpool-street for a distance of 112·57 links; thence south-westerly by a line bearing 30 degrees 47 minutes 2 seconds for a distance of 581·62 links; thence further south-westerly by a line bearing 51 degrees 23 minutes 33 seconds for a distance of 175·34 links to Campbell-street; thence along the north-east side of Campbell-street by a line bearing north-westerly 151 degrees 6 minutes 33 seconds for a distance of 107·6 links; thence north-easterly by a line bearing 51 degrees 23 minutes 33 seconds for a distance of 137·9 links; thence further north-easterly by a line bearing 30 degrees 47 minutes 2 seconds for a distance of 298·74 links; thence further north-easterly by a line bearing 51 degrees 14 minutes 25 seconds for a distance of 51·65 links; thence north-westerly by a line bearing 140 degrees 21 minutes 38 seconds for a distance of 19·16 links; and thence north-easterly by a line bearing 30 degrees 47 minutes 2 seconds for a distance of 246·5 links to the point of commencement, be all the bearings, area, and distances a little more or less,—being a strip of land 70 feet wide throughout, and said to belong to Mrs. D. C. F. Scott and Joseph Burdekin Holdsworth, and bounded on or towards the north-east by Liverpool-street, on or towards the south-east and north-west by other parts of the properties said to belong to Mrs. D. C. F. Scott and J. B. Holdsworth, and by a reserve for drainage and a lane 20 feet wide, and on or towards the south-west by Campbell-street.

2nd.—All that piece or parcel of land containing by admeasurement three roods thirteen perches and seven-tenths of a perch, situate in the parish of Alexandria, county of Cumberland, and Colony of New South Wales, and being a part of the estate known as the Barcom Glen Estate: Commencing at the north-easternmost corner of allotment numbered twenty-four in J. B. Holdsworth's subdivision of part of Barcom Glen Estate; thence running south-easterly by a line bearing 151 degrees 6 minutes 33 seconds along the south-western boundary of Campbell-street for a distance of 107·6 links; thence south-westerly by a line bearing 51 degrees 23 minutes 33 seconds for a distance of 381·1 links; thence further south-westerly by a line bearing 58 degrees 18 minutes 49 seconds for a distance of 224·74 links; thence westerly by a line bearing 270 degrees 52 minutes for a distance of 278·45 links to West-street; thence north-easterly by a line bearing 208 degrees 44 minutes along the south-east side of West-street for a distance of 119·9 links; thence easterly by a line bearing 270 degrees 52 minutes for a distance of 191·5 links; thence north-easterly by a line bearing 58 degrees 18 minutes 49 seconds for a distance of 137·35 links to Ice-street; thence south-easterly by a line bearing 148 degrees 43 minutes 33 seconds along the south-western side of Ice-street for a distance of 81·4 links; thence north-easterly by a line bearing 60 degrees 19 minutes along the south-eastern end of Ice-street for a distance of

50·03 links; thence north-westerly by a line bearing 148 degrees 43 minutes 33 seconds along the north-eastern side of Ice-street for a distance of 83·15 links; and thence north-easterly by a line bearing 51 degrees 23 minutes 33 seconds for a distance of 392·86 links to the point of commencement, be all the bearings, area, and distances a little more or less,—being a strip of land 70 feet wide throughout, intersecting street excepted, and said to belong to Jos. B. Holdsworth, Catherine Nichols, Naomi Dobson, Patrick Toner, John Stedman, Mrs. R. S. Dobson, Louisa Marshall, and Jane M. Haines, and bounded on or towards the north-east by Campbell-street, on or towards the south-east and south by other parts of properties said to belong to Jos. B. Holdsworth, Naomi Dobson, John Stedman, Mrs. R. S. Dobson, and Jane M. Haines, and by a reserved road on or towards the north-west by West-street, and on or towards the north and north-west by a property said to belong to Martha Goddard; by other parts of the properties said to belong to Louisa Marshall, Patrick Toner, and Catherine Nichols, and by Ice-street and a reserve for drainage.

3rd.—All that piece or parcel of land containing by admeasurement one rood six perches and eight-tenths of a perch, situate in the parish of Alexandria, county of Cumberland, and Colony of New South Wales, and being part of the estate known as Barcom Glen Estate: Commencing at the easternmost corner or angle of a piece of land conveyed by Thomas West to trustees for the use of the tenants as a water reserve; thence running south-westerly by a line bearing 208 degrees 44 minutes along the north-western side of West-street for a distance of 95·2 links; thence westerly by a line bearing 270 degrees 52 minutes for a distance of 160·85 links; thence north-westerly by a line bearing 290 degrees 12 minutes for a distance of 162·6 links to Great Barcom-street; thence north-easterly by a line bearing 247 degrees 53 minutes 50 seconds along the south-eastern side of Great Barcom-street for a distance of 157·6 links; thence south-easterly by a line bearing 290 degrees 12 minutes for a distance of 27·95 links; thence easterly by a line bearing 270 degrees 52 minutes for a distance of 198·75 links to West-street; and thence south-westerly by a line bearing 208 degrees 44 minutes along the north-western side of West-street for a distance of 24·7 links to the point of commencement, be all the bearings, area, and distances a little more or less,—being a strip of land 70 feet wide throughout, and said to belong to John E. Holdsworth, Mary Ann Wilcox, Charles D. Clements, Jane M. Holdsworth, Jos. B. Holdsworth, and to Henry Lane and Jos. B. Holdsworth, as trustees for a water reserve; and bounded on or towards the south-east by West-street, on or towards the south by other parts of the properties said to belong to the said John E. Holdsworth, Mary Ann Wilcox, Jane M. Holdsworth, and Jos. B. Holdsworth; on or towards the north-west by Great Barcom-street; and on or towards the north by other parts of the properties said to belong to Jane M. Holdsworth and Charles D. Clements, and by other parts of the water reserve.

In witness whereof I have hereunto set my Hand, and caused the Great Seal of the Colony to be hereto affixed, at Government House, Sydney, this twenty-third day of June, in the year of our Lord one thousand eight hundred and eighty-six, and in the fiftieth year of Her Majesty's Reign.

By His Excellency's Command,

W. J. LYNE.

GOD SAVE THE QUEEN!

Sydney: Thomas Richards, Government Printer.—188

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

MESSRS. A. FORSYTH & CO. *v.* MINISTER FOR PUBLIC WORKS.

(CORRESPONDENCE, &c.)

Ordered by the Legislative Assembly to be printed 30 *June*, 1886.

RETURN to an *Order* made by the Honorable the Legislative Assembly of New South Wales, dated 30th June, 1886, That there be laid upon the Table of this House,—

"Copies of all papers, letters, reports, minutes, and other documents, relating to the claim for compensation, and the action-at-law thereon, made by Messrs. A. Forsyth & Co. against the Minister for Public Works, tried in the Supreme Court in August, 1884."

(Mr. Forsyth.)

Commissioner's Minute.

MR. PIPER, look up all papers, and see me with them. I think this should be opposed for legal reasons.

Copies of all the papers are herewith, but confidential correspondence between the Crown Solicitor and Department, and an opinion of Mr. Salomon's, which it is not desirable should be made public, as it might prejudice case if again brought into court. W.C.B., 24/6/86.

SCHEDULE.

643—A

[805 copies—Approximate Cost of Printing (labour and material), £9 5s. 0d.]

MESSRS. A. FORSYTH & CO. *v.* MINISTER FOR PUBLIC WORKS.

No. 1.

A. Forsyth & Co. to Mr. J. M. Smail.

Sir, 6 January, 1883.

We would draw your attention to the dangerous state of Bourke-street where the sewerage works are going on. Before the street was opened up we had a good road, but the contractors have torn up the part of it for traffic, and have taken no trouble to put the other portion in a passable state.

It is now almost impossible to get a load through, being both dangerous and cruel to horses to have to drag a load through the street in its present condition.

We would ask you to compel the contractors to make a fair temporary road as they open up the street, and also to put that part where the street is already opened up in a passable condition.

A. FORSYTH & CO.

No. 2.

Mr. J. M. Smail to Stewart & Co.

Sirs, Sewerage Office, Bourke-street, 6 January, 1883.

Messrs. Forsyth have complained about state of temporary road along side of sewer trench. Will you be good enough to have such temporary track kept in trafficable order, so as to obviate any further complaints.

I remain, &c.,

J. M. SMAIL.

No. 3.

A. Forsyth & Co. to Mr. J. M. Smail.

Sir, 10 February, 1883.

We again draw your attention to the dangerous and almost impassable state of Bourke-street where the sewerage works are going on.

It is now impossible to get a load to town from our factory by going south to Elizabeth-street, and Bourke-street north of our factory is almost as bad, so that we are almost stopped from carrying on our business.

If the street is not put in a fair passable condition at once we shall see the Minister of Public Works about it, and if that has no effect we shall summon the contractors.

A. FORSYTH & CO.

This letter was attended to by contractor repairing the temporary track the following Monday morning.—J.M.S.

No. 4.

The Engineer-in-Chief to Mr. J. M. Smail.

Department of Roads and Bridges, Sydney, 24 February, 1883.

Messrs. Alderson & Forsyth have called with reference to the road in Bourke-street; they say that contractor has made road impassable and for the last three months has done nothing. By contract he is bound to keep road in repair, and they state that in lieu of doing so he is filling in the ballast.

W. C. BENNETT.

Why did not Mr. Smail report or forward the complaints of Messrs. Alderson & Forsyth? Mr. Smail,—Report on separate paper herewith.—J.M.S., 24/2/83. The Engineer-in-Chief.

No. 5.

Mr. J. M. Smail to The Engineer-in-Chief.

Superintending Officer's Report on Engineer-in-Chief's memo. *re* complaint by Messrs. Alderson and Forsyth.

In answer to the Engineer-in-Chief's memo., 24/2/83, I beg to state that the portion of the road referred to is not impassable, but from force of circumstances is heavy in places. I saw Mr. Forsyth, junior, this morning, and asked him to show me the portion of the road he particularly referred to. It turned out to be a length of about 4 chains from Lachlan-street upwards; this was rutted in places on one track, there being sufficient room to avoid the rutted portion, as the sewer trench had been filled in on the above length. Mr. Forsyth is the only one on the road who has complained to me. He sent me a letter on the 6th January complaining of the state of temporary road in the vicinity of his works. I wrote to the contractor informing him of the complaint, and he spread some ballast on the track, which, I understood, satisfied Mr. Forsyth. When the 30-inch main broke and caused a breach in the road, the track was naturally contracted, and caused a temporary inconvenience to traffic. On the first opportunity this track was made wider and passable, although heavy; this could not be otherwise from the nature of the soil. The contractor is aware of the fact that he has to maintain temporary roads during the progress of the works, for it has been impressed on him several times by myself. I certainly never considered the track so bad as represented to the Engineer-in-Chief. I think it is obvious if carts with a double load of bricks, weighing close upon 3 tons, can traverse the road without danger, the local traffic is not likely to

be

be interfered with to the extent that it is made out. I endeavour to inconvenience local traffic as little as possible; but I think that it will be allowed that carrying out work of the description we are doing through a sandhill, and the original ballasted track being little more than 12 ft. wide, and in very bad repair at places, it is impossible at all times to keep a first-class track available. I have informed Mr. Forsyth the ruts he pointed out would be filled in. In reference to contractor filling in the ballast taken off road as filling it is not correct. It would not pay the contractor to pay 6s. or 7s. a yard for ballast to supply the place of that used as filling. I did not forward the complaints to the head office, as I did not consider them of sufficient importance to warrant me doing so.

J. M. SMAIL,
24/2/83.

Inform Messrs. Alderson and Forsyth, and that Mr. Dyson reports Elizabeth-street is being repaired.—W.C.B., 26/2/83. Messrs. Alderson and Forsyth informed, 27/2/83.

No. 6.

The Engineer-in-Chief to Mr. A. Forsyth and The Hon. W. M. Alderson, M.L.C.

Department of Public Works,
Office of Commissioner and Engineer for Roads and Sewerage,
Sydney, 27 February, 1883.

Sirs,

Referring to the interview I had with Mr. Forsyth, Mr. Alderson, and yourself on Saturday last, with reference to the condition of a certain portion of road in Bourke-street, in the vicinity of your works, I have the honor to inform you that Mr. Smail, who has charge of the Sewerage Works in the Southern Division, reports that the portion of road referred to is not altogether impassable, but, from continual traffic, is rather heavy in some places, and that the part complained of appears to be a length of about 4 chains from Lachlan-street upwards. This was rutted in places on one track; but as the sewer trench had been filled in on the above length, there was sufficient room remaining to avoid the rutted portion; and when you complained about the road the contractor was informed that he would have to repair any damage done, which he accordingly did by laying ballast on the track, and this was understood to meet with your approval. The contractor has since been reminded that he is expected to maintain temporary roads during the progress of works, in accordance with the terms of his contract.

Respecting repairs to Elizabeth-street, Mr. Dyson reports that he has had men employed during the past week breaking in ballast and clearing off sand, and so soon as this is completed the metal will be put on.

I have, &c.,
WILLIAM C. BENNETT,
Engineer-in-Chief for Sewerage.

No. 7

Mr. A. Forsyth to The Engineer-in-Chief.

Sir,

We are in receipt of your letter of the 27th ultimo *re* sewerage works in Bourke-street, for which we beg to thank you.

The information given in Mr. Smail's report is incorrect and misleading. He says the road is not altogether impassable; if he means for foot passengers, horsemen, or empty drays, he is correct, but as to loaded drays it cannot be passed over with more than half a load and having double the number of horses, and then only after being repeatedly stuck up in the sand, and when he states that "as the sewer trench had been filled in" where the road was the worst "there was sufficient room remaining to avoid the rutted portion" he is simply misleading you. There was neither ballast nor any other covering on the sand to enable a loaded dray to go along the portion of road referred to, and it still remains in the same state.

There were some slight repairs effected a few days after Mr. Alderson and the writer interviewed you, but they are altogether insufficient and impose on us a heavy daily loss *besides serious interruption to our business for which we will have to seek redress* unless the road is at once put in a reasonably passable state. A visit will prove all we state.

I am, &c.,
A. FORSYTH.

Mr. Smail.—W.C.B., 7/3/83. Report herewith.—J.M.S., 15/3/83.

No. 8.

Mr. J. M. Smail to The Engineer-in-Chief.

Sewerage, Sydney, 15 March, 1883.

Subject;—Messrs. Forsyth & Co. complaining of state of Bourke-street, Waterloo, on sewerage works in progress.

In reply to Mr. Forsyth's letter of date, I beg to state that I take exception to Mr. Forsyth's statement that my report is "incorrect and misleading." What I have stated are actual facts and can be borne out by the Inspector and others on the works. As to the road being only passable for "horsemen, empty drays," and the like, is simply nonsense. I have seen as well as from information kept on the work that loaded drays, not half-loads, could pass along without the sticking-up and obstructions stated by Mr. Forsyth; further, Mr. Forsyth's own drays have passed along with a load drawn by two horses, which I would consider a good load for the road before it was ever touched by the contractor. The road will be restored to a passable state when the filling in is sufficiently consolidated to receive the ballast taken up, which I think any unprejudiced person will admit was very small for a ballasted road. The length we have dealt with in the vicinity of Mr. Forsyth's works had no ballast in places; others very scant. It appears

to

to me that Mr. Forsyth wants to bounce either the contractor or the Department into making a good ballasted road for him, which he never could get the Borough Council to do. His nephew has admitted to me that the road some time ago was so bad that they had to send men to put stone on the road to make it passable. The length of ballasted road we have yet to deal with, viz., from 42 chains to 59 chains and from 79 chains to 87 chains, is in as bad a condition as any road could possibly be, and during the time I have dealt with the southern drainage nothing beyond putting a few loads of ballast in some very bad holes has been done to it. Mr. Forsyth's captiousness dates some time back; he started first by objecting to the sewer being taken up the centre of the road as he said it would interfere with his business as he would not be able to get in or out. This was not borne out, for when the sewer was being taken past his premises he was put to no inconvenience on this score. I further beg to add that the other business people recognizing the importance of the work in hand, accept the temporary provision made for them and do not object to the slight inconvenience they are put to until the whole road is available for them, and as to the concluding statements of Mr. Forsyth's letter, underlined,* his reason for saying so is best known to himself, but personally I consider them exaggerated.

* *Italics.*

J. M. SMAIL.

P.S.—Contractor has been instructed to restore the road surface on that portion of sewer completed and consolidated. Mr. Forsyth might be informed accordingly.

Inform.—W.C.B., 16/3/83. Informed, 16/3/83.

No. 9.

The Engineer-in-Chief to Mr. A. Forsyth.

Department of Public Works,
Office of Commissioner and Engineer for Roads and Sewerage,
Sydney, 16 March, 1886.

Sir,

In answer to your letter of instant, having reference to the condition of the road in Bourke-street, Waterloo, I have the honor to inform you that Mr. Small reports that he has instructed the contractors to restore the road surface over that part of sewer which is now completed, and the contractors have again been reminded that they are expected to maintain temporary roads during the progress of works in accordance with terms of their contract.

I have, &c.,
WILLIAM C. BENNETT,
Engineer-in-Chief for Sewerage.

No. 10.

Mr. J. Williamson to The Secretary for Public Works.

Williamson's Chambers, King-street, Sydney, 4 April, 1883.

Dear Sir,

I am instructed by Archibald Forsyth and Company, of the rope works, Waterloo, to demand from you the sum of five hundred pounds (£500) for damages sustained by their firm by reason of injuries sustained by them through the cutting up and removing the soil of the roadway in opening and constructing the sewerage over and through the roadway by which my clients have to approach their manufactory and rope-works, situate at Waterloo.

My clients estimate that they are at least put to the expense of forty pounds (£40) per week through the above injuries, and therefore I must request your immediate attention to this notice in order that the damages may be stopped by the repairing and making of the same roads, and the prevention of any further annoyance or injury to my clients.

Yours, &c.,
JOHN WILLIAMSON,
Per N.B.

Roads, B.C., 9/4/83.—J.R.

No. 11.

The Engineer-in-Chief to The Under Secretary for Public Works.

Sewerage, Sydney, 11 April, 1883.

Report on Mr. A. Forsyth's complaint *re* state of road leading to his works.

The road through which the sewer is being made was over a sandhill 1 chain wide. Some four or five years ago a narrow track 18 feet wide, of soft stone, was made through it by the Waterloo Council, leaving a margin of deep sand on each side. The sewer passes through the centre of the street. The old stone, which was very scanty, was taken up by the contractor, put on the side to make a temporary track, but being insufficient has disappeared in the sand under the traffic, which has now to pass over a very heavy road.

Mr. Forsyth has given some hemp refuse from his works which makes the draft easier. Though the contractor is bound to keep up temporary roads I could not equitably call upon him to supply sandstone for that purpose; indeed I doubt if he could obtain sufficient in time to make it useful, and I think the sand road complained of is better than a new stone road would be for some time, and when the sewer was completed all stone put in such temporary roads would be useless for permanent purposes.

The contractor will be obliged to supply free to the Government equal to about half the stone on road, to make up loss and waste; this will cost him (say) £230.

With a view to obviate cause of Mr. Forsyth's complaint, I would advise that this amount be supplemented by an equal sum from the Government, to be applied to putting 1½ cube yards to the lineal yard of approved ballast on road, which will make it much better than it ever has been, but this should only be done on condition that Mr. Forsyth withdraws all claims for damages sustained, or to be sustained, from this cause, and the offer should be made without prejudice.

I think it better to expend some money in doing more than we have a right to do to a road than to spend the amount in law.

W.C.B., 12/4/83.

Submitted. I approve of the Commissioner's suggestion as to amicable settlement, although it is evident that Messrs. Forsyth's damage is entirely overstated at £40 per week. The sooner the offer is made, and "without prejudice" the better, as the claim is an accumulating one; of course it must be not only without prejudice but on the understanding that Messrs. Forsyth withdraw their claim.—A.S., 13/4/83. J. Williamson, Esq., 19/4/83.

No. 12.

The Under Secretary for Public Works to Mr. J. Williamson.

Sir, Department of Public Works, Sydney, 25 April, 1883.

Referring to your letter of the 4th instant, forwarding claim of Messrs. Forsyth & Co., for damage to road leading to their property by the Sydney Sewerage Works, I am directed to inform you that it is found that the contractor's loss to supply stone, replace what has been taken up on this road, will amount to £230, and the Secretary for Public Works proposes, without prejudice, if your clients will waive all claim in this matter that an equal sum will be granted by the Government to put the road in thoroughly good order.

I have, &c.,
JOHN RAE.

No. 13.

Mr. J. M. Smail to The Engineer-in-Chief.

Sydney Sewerage, Botany, 13 July, 1883.

Subject:—*Re* road repairs, Bourke-street, Waterloo.

With reference to the above case I wish to draw the Engineer-in-Chief's attention to the fact that Mr. Forsyth informed me last Wednesday, 11th instant, that their action against Government had not been withdrawn, and whatever was done to the road would not affect their claim, as the repairs were a matter between the Waterloo Council and the Government.

Under the circumstances would it be advisable to proceed with the improvements?

J. M. SMAIL.

I think the repairs should be proceeded with; I have verbally instructed Mr. Smail to proceed. We are in possession of very conclusive evidence of the prior state of road should Mr. Forsyth go to law. —W.C.B., 14/7/83. Under Secretary, B.C. Submitted. Let work be proceeded with at once.—F.A.W., 17/7/83.

No. 14.

Mr. A. Forsyth to The Secretary for Public Works.

Subject:—Mr. A. Forsyth claiming £1,000 for damage to his business, Bourke-street.

Returned from Crown Solicitor, with front page of sheet, containing Mr. Forsyth's claim, torn off.—1/12/85 (after the trial).

I append report of the meeting of the Waterloo Council on 12th October, 1882, which is, I think, sufficient evidence of the state of the road before our operations commenced. The 121st section provides that a sufficient road shall be maintained; we are in a position to prove that a road was maintained "in a state as convenient for passengers and carriages as the road so interfered with, or as nearly so as may be," and that in accord or in excess of the 122nd section the road will, when restored, be better than ever it was; and with regard to the 90th section the road was kept as free from all obstructions and annoyances as practicable.—W.C.B., 20/7/83. Under Secretary, B.C. Submitted.—J.R., 23/7/83. Seen. Push on reformation of this road as fast as possible; and I wish a good job made of it.—F.A.W., 25/7/83. Mr. Bennett, B.C., 26/7/83.—J.R. Send copy to Mr. Smail, with a request that he will at once report progress. Should not some communication be made to Crown Solicitor?—W.C.B., 27/7/83. Copy made and sent to Mr. Smail, 30/7/83. Mr. Piper, B.C. Upon inquiry at Crown Solicitor's Office I ascertain that they have already received letters on this subject from Mr. Forsyth, and advise that these papers be forwarded to them, with instructions how to act.—F.C.P., 2/8/83. Engineer-in-Chief for Sewerage.

No. 15.

Extract.

From *Daily Telegraph* of 16/10/82, *re* Bourke-street, Waterloo.

Municipal Councils.

Waterloo.—An ordinary meeting of this Council was held on the 13th instant. Present—The Mayor (Alderman Hogan), with Aldermen Evans, Gray, Harrisky, Cole, Mulder, and Smith. James Schinell complained of the wretched state of the footpath in Elizabeth-street, and offered to contribute a moiety of the cost of asphalting. Alderman Mulder thought the applicant had not much need to grumble, and after some little discussion the letter was received. The resignation of Alderman Nelson was accepted and Alderman Mulder interjected a regret that his late *confrère* had made such a fool of himself and the Council, and had put the borough to expense. The local manager of the A.J.S. Bank drew attention to the fact that the account was overdrawn to the extent of £792 7s. 3d., and requested a guarantee before this amount was increased; received. The Tramway Department intimated, in reply to a complaint regarding the dusty state of the Botany Road, that all lines were watered once daily. A general opinion was

was expressed that this necessary work could at present be more efficiently done with a watering-pot. A petition from a number of ratepayers, drawing attention to the disgraceful state of Bourke-street, and stating that several accidents had lately occurred, consequent upon negligence in not filling up the holes for which the street is now noted, was received. A report from the Inspector, intimating, among other matters, that the clearing of the gutters was not attended to in a satisfactory manner, was also received. A considerable amount of discussion ensued regarding a water-trough in front of an hotel on the Botany Road, which the authorities want removed, as it interferes with the tram traffic. The Mayor explained the circumstances of the case. Alderman Mulder was furious at such an attempt being made to interfere with the liberty of the subject, and complained of some of the aldermen wishing to throw dirty water in a ratepayer's face. The matter ultimately lapsed. It was stated that several accidents had lately occurred in Bourke-street and Botany Road, consequent upon the defective state of the same; and Alderman Gray suggested that the difficulty be overcome by signing the required guarantee, and getting the funds from the Bank.

A correspondent writes—"Bourke and Botany streets, Waterloo, are at present in a very defective state, the former especially so, being literally full of holes. The consequence is that accidents are almost of daily occurrence. In Bourke-street drays are continually bogged. The other night a cabman was flung from his seat, and yesterday a cart loaded with malt was upset, and the shaft horse injured. An accident also occurred yesterday in Botany-street, owing to a large hole made in the road by a heavy waggon. It appears that the driver of a light cart not noticing the trap drove into it, and as a consequence he was jerked out, severely injured, and had to be conveyed home in a cab. The Council excuse themselves for this undesirable state of things on the plea that they have no money. Such a plea, however, would not hold good in a Court of law; and as the expense involved in one single action would more than cover the cost of necessary repairs, it is hoped the aldermen will give these streets early attention."

No. 16.

Mr. J. M. Smail to The Engineer-in-Chief.

Sewerage, Sydney, 31 July, 1883.

Repairs to Bourke-street, Waterloo.

The Contractor has restored the road surface up to 2 miles 4 chains, and is continuing same to the Redfern boundary.

The work being done by the Department is making good progress. The length of road at present improved is 77 lineal yards; if greater progress is required I will have to put on more men; at present I have two engaged.

There is a good firm track from Forsyth's to top of hill, capable of carrying any loading likely to be put upon it.

J. M. SMAIL,
31/7/83.

In four or five days it will be better than when work commenced. Put on more men; keep an accurate account. File.—W.C.B., 31/7/83.

No. 17.

Mr. J. M. Smail to The Engineer-in-Chief.

Sewerage, Sydney, 9 April, 1884.

Witnesses expenses in case Forsyth *v.* Wright.

Two witnesses, Lawler and Ringrose, have applied to me for their expenses for the days they were in attendance at Court. I asked them to submit their claim in writing; I forward them herewith. Mr. Walsh, they say, promised to pay them, but as he is on circuit he cannot do so. The applicants want the money before Easter.

I have drawn out vouchers for the amounts (total, £5 2s.), the claims having been reduced to what I consider a fair allowance. The Engineer-in-Chief might grant the application as it appears a case of necessity.

J. M. SMAIL.

Pay—give cheque in advance.—W.C.B., 9/4/84. Mr. Piper. Cheque drawn; money will be forwarded to Mr. Smail to morrow.—F.C.P., 9/4/84. Witnesses paid. Vouchers herewith.—J.M.S., 17/4/84.

No. 18.

A. Forsyth & Co. to The Acting Secretary for Public Works.

Sir,

339 Kent-street, Sydney, August, 1884.

We beg to lay before you the following particulars relating to the sewer made by your Department, in Bourke-street, Waterloo, by which we have sustained a large amount of injury and loss.

The works commenced in November, 1882, near to our rope works. This portion of Bourke-street runs through a sandhill; on this sand a roadway 20 feet wide was made with sandstone ballast. It was not a good road but on it we were able to carry loads of 2 tons and over with a pair of horses.

The sewer excavation was made in the centre of the ballasted track, and where it was opened compelled us to go with our carts over the naked sand. The Act under which the works were carried out provides that the Board shall before breaking up any road, make a temporary one, and maintain it in as good condition as the one interfered with during the time the works are being carried out. As we had great difficulty in carrying on our traffic through loose sand, we applied several times to the resident inspector under the Board; he promised to have a substituted road made, but nothing was done. We

wrote

wrote and interviewed Mr. Bennett, Commissioner for Sewers, several times; but although he promised to have a temporary road made nothing was done, and matters got worse as the cutting got extended, for although the sand was filled into the excavation in some portions the ballast was not restored until August, a period of nine months, during which we were compelled to carry the traffic on through the naked sand for a distance varying at different times from 400 yards to 900 yards, and compelled to reduce our loads from 2 tons to 1 and sometimes to 15 cwt., and had often to employ three horses for this quantity on this portion of the road; the number of loads per day had likewise to be reduced.

In July, failing to get the Board to do anything to the road, we sent a notice of the injury and damage we had sustained, claiming compensation, in accordance with the 129th section of the Act.

During the above period the road was in such a bad condition that we ruined four of our horses, which became unfit for our work, and had to be sold at great loss. Our vehicles and harness were often broken and damaged (and subsequent to the notice for compensation one valuable horse died from the effects of the work), but, apart from the loss by horses, vehicles, and harness, the cost of our cartage from diminished loads and reduced number per day was doubled; previous to the breaking up of the road it cost 5/- per ton, after not less than 10/.

The Act, section 130, prescribes that within 60 days after receipt of notice for compensation the Minister shall cause an appraisement to be made of the injury and damage, and shall inform the claimant of such appraisement; but no notice of such appraisement has been made to us up to present date.

In October our legal advisers were of opinion that an action would lie at common law, and, as this form of action did not require the appraisement mentioned in the Act, it was deemed advisable to sue at common law, and a writ was issued against the Minister in November last. The action was tried last May's sittings, and resulted in a verdict for the plaintiffs for £700. On this verdict the Minister applied to the full Court to have the verdict entered for the defendant. The case was argued before the full Court on the 8th inst., and the verdict was entered for the defendant.

It will be seen from the judgment of the Full Court (a report of which we append), that the Minister had failed to do either of two things directed by the Act to be done by him: He had not made an appraisement nor denied his liability, so that the only two modes contemplated by the Act for recovering damage is closed against us.

Such being the state of the case we now ask you to have the appraisement made of the injury and compensation claimed, and as counsel for the Minister stated that the damage awarded by the verdict was excessive, we are willing to place our books under the inspection of such appraiser from which he can ascertain the actual amount of cartage done during the period that the road was broken up, and likewise gain information on loss from horses, vehicles, and harness, and as regards the extra cost of cartage. Although the track in its then state cannot be seen it can be pretty correctly estimated from the nature of the soil, and information can be got from many persons (not interested in the amount of compensation) that went over the road during the construction of the sewer, and in addition such appraiser can read the evidence from the Judge's note, a verified copy of which is in our possession.

As regards the heavy costs incurred by the trial we will no doubt have to bear our own costs, but we respectfully submit that as this abortive trial has arisen through the Minister's non-compliance with the provisions of the Act, it is only fair that the Board should forego their costs in the case. No doubt the Board can legally enforce the payment of their costs, but we hope that, standing as you do in the present case as the representative of the Government, you will prefer justice to law, as has been frequently done in the past both by the Government and Legislature when dealing with individuals.

Trusting you will give this matter early attention and have an appraisement made of the injury and compensation claimed, and carefully consider the grounds on which we ask you to forego the costs of the Board in the late action,

We have, &c.,
A. FORSYTH & CO.

Mr. Bennett, for report.—G.R.D., 14/8/84. B.C., 15/8/84.—J.R. This is a legal matter and the paper should go on to the Crown Solicitor. I attach a minute made on the Crown Solicitor's letter of 8th instant, with reference to this case.—W.C.B., 18/8/84. Under Secretary, B.C. Forward to Crown Solicitor.—J.R., B.C., 21/8/84.

No. 19.

Extract from *Sydney Morning Herald.*

SUPREME COURT—THURSDAY, AUGUST 7.

In Banco—(Before their Honors the Chief Justice, Mr. Justice Faucett, and Mr. Justice Innes.)

FORSYTH AND ANOTHER V. WRIGHT.

Mr. M. H. Stephen, Q.C., Mr. Salomons, Q.C., and Mr. C. B. Stephen, instructed by the Crown Solicitor, appeared on behalf of the defendant to move that the rule *nisi* granted on the 29th July to enter the verdict for the defendant be made absolute.

Mr. Owen, Q.C., Mr. W. J. Foster, and Mr. Edmunds, instructed by Mr. J. Williamson, appeared in opposition to the rule.

The arguments in this case were resumed and concluded.

Mr. Salomons submitted that plaintiffs must go for compensation under the 129th, 130th, 131st, and 132nd sections of the Metropolitan Water and Sewerage Act, and even if an action could be brought under those sections, notice was required under the 147th section of the Act, and this was not given. Even if the defendant denied his liability, plaintiffs were bound, before commencing their action, to give notice, but they had not done so. The case was very similar to that of Olenshalager v. the Commissioner for Railways, heard a few days ago.

Mr. C. B. Stephen, on the same side, also argued that if the Government denied their liability, they were entitled to notice under the 147th section of the Act, and this notice had not been given.

Mr. Owen contended that in all cases of compensation under the Act it was provided that the cases must fall under one or other of the two categories; either it must be a case in which there had been a denial of liability, or a failure to arrive at an agreement between the claimant and the Minister. This was not a case of denial, and it must be taken as a case of non-agreement, and therefore plaintiffs were entitled, under the 129th and 130th sections of the Act, to bring the action. As to the ground whether the action could be properly brought outside the Act, he submitted that it could properly be brought for injury done by the Minister, not in carrying out works under the authority of the Act, but in doing certain works which he was not authorized to do at all by the Act. By section 121, which was the section under which this action was brought, it was provided where it was considered necessary to cut through a road that before they put a pick into the road or disturbed a stone they must make and maintain a road equally good. The section said "that the Board shall, before the commencement of any such operations, cause a sufficient road to be made instead of the road to be interfered with, and shall, at the public expense,

expense, maintain such substituted road in a state as convenient for passengers and carriages as the road so interfered with, or as nearly so as may be." He submitted that before they broke up the road so as to make it "more than usually inconvenient" for traffic they must make and maintain a substituted road. No doubt the Government considered it necessary, for the purpose of making the sewer, that they should cut through the road, but before they did that they were bound to make a convenient substituted road; and the gravamen of the plaintiff's complaint was that the Minister did not do this, and that they cut through the road and made it impassable. The Act only authorized the Minister to break up the road after he had made a substituted road, but he did this before making a substituted road. Section 129 did not in the least refer to the present case, because the injury plaintiffs suffered from was not any injury done under the Act, but because the Minister had not done something which he ought to have done under the Act, namely, making a substituted road. He contended that whether the action was taken to be under the Act or outside the Act, it was properly brought.

Mr. Foster, on the same side, argued that the word "compensation" referred to compensation for work done under the Act, and was limited to that, but compensation for work not done under the Act was provided for by law.

The Chief Justice said that under the Metropolitan Water and Sewerage Act, 43rd Vic., No. 32, section 40, paragraph 5, power was given to the Minister for Works to enter upon any lands, streets, roads, or thoroughfares, and construct and lay, or place therein any drains or pipes, and may repair, alter, cut-off, or remove the same, or may enter upon such lands, streets, roads, or thoroughfares for the purpose of repairing any watercourses or other works being the property of the Government or under their control, provided that the Minister shall make full compensation for all damage or injury committed in the exercise of such powers, and the amount of such compensation shall, in every case where the owner or claimant cannot agree, be ascertained and be dealt with under the provisions of the Act. By section 121 of the same Act it was enacted—"If, in the exercise of the powers hereby granted, it be found necessary to crosscut through, raise, sink, or use any part of any road, whether carriage road, horse road, or tram road, or railway, either public or private, so as to render it impassable for, or dangerous, or more than usually inconvenient to passengers or carriages, or to the persons entitled to the use thereof, the board (previously the Minister) shall, before the commencement of any such operations, cause a sufficient road to be made, instead of the road to be interfered with, and shall, at the public expense, maintain such substituted road in a state as convenient for passengers and carriages as the road so interfered with, or as nearly so as may be." The Minister for Works, armed with these powers, proceeded to perform certain works in a street in this city, and these works were of such a character as to interfere with the road in which they were constructed, so as to make it less convenient than it was before. Plaintiffs, being possessed of a rope walk, which was approached or approachable with vehicles only by means of this road, were interfered with in their business by what defendant did; and for the injury which they sustained by the performance of these works, and by not making, as required by the 121st section of the Act, a roadway equally convenient while these works were in progress and while the impediment was in existence, they sued for damages; and in the second count they set out the circumstances he had mentioned, and the damage they sustained by reason of the Minister not keeping the roadway, and a convenient roadway, in good order. To all the counts of plaintiffs' declaration the defendant had pleaded "that the claims of plaintiffs are in respect of certain alleged damage and injuries sustained by them by reason of the construction of certain works done under the authority of the Act 43 Vic., No. 32, in respect of which plaintiffs have given notice of claim for compensation; that the defendant has not denied any such liability in respect to the matter, and that the defendant says that the report and appraisement of the nature and amount of such injury or damage, as required by the 130th section of the Act, has not yet been made nor notified to the plaintiffs, whereby the amount of compensation, under the 131st section of the Act, cannot be decided or tried in this action." The case went down for trial, and the jury found on the second issue for the plaintiffs, with £700 damages. Leave was reserved to apply for a new trial, or to enter a nonsuit, or that the verdict which was given for the plaintiff should be entered for the defendant; and that was the matter which they had now to determine. Well, the Act under which this interference with the road took place and which has given rise to this action and controversy, was, so far as regarded the subject matter of this inquiry not easy to determine. He could see that the clauses were to a large extent, as was frequently the case in matters of this kind, copied from other enactments, and sometimes the sections were not drawn with that precision which was desirable in sections of this character. Some things were clear enough in this enactment. The power given to the board, and in the absence of the board, to the Minister, to do this work, was very plain. By the 93rd section there could be no question that authority was conceded to enter upon these public roads and interfere with them in the way it was interfered with in this case, and it was quite clear that any compensation that might be demandable for anything done in carrying out the provisions of the enactment must be dealt with, not at common law, but under the provisions of the Act. Power was given very plainly indeed, and it was also pointed out that full compensation could be demanded by persons who were injured by the performance of these works; and it was pointed out with equal plainness that the compensation to be given should be ascertained under the provisions of the Act. Then by the 121st section it was plain that if a road was interfered with in such a way as to render it impassable, dangerous, or more than usually inconvenient, a sufficient road must be made and maintained in its stead, and must be made before the commencement of these operations which created this impassable or inconvenient condition of things. All that was plain enough. Now they had to see what were the provisions made for ascertaining the amount of compensation, and they came to clause 129, which was in these terms:—"Every person claiming compensation in respect of any injury or damage sustained by him by reason of the construction of any works under this Act, or of any work or other matter done under the authority of this Act (not being injury caused by the permanent taking of land), shall serve a notice in writing upon the Minister, and a like notice upon the Crown Solicitor, which notice shall set forth the nature of the injury or damage which he has sustained, or will sustain by reason of such construction, work, or matter as aforesaid: Provided always that nothing in this part contained shall affect or prejudice the right of any such claimant to maintain an action in the Supreme Court as he might heretofore have done in case the Minister shall deny any liability in respect of the matter of the claim for compensation. But in every such case such action shall be subject to the provisions hereafter in p. 7 contained." The words were certainly comprehensive, and included a number of injuries to individuals done under the authority of the Act. What was done here was plainly under the authority of the Act, and whether it was done negligently or not was perfectly immaterial because it was only when the requirements of the Act had not been attended to, and when the provisions of the Act were not complied with, that a cause of action would arise. The cause of complaint was that something which the Act required to be done had not been done, and that was one of the causes of damage specially pointed out by the enactment. The section said that notice of such injury or damage should be served upon the Minister, and a like notice for the Crown Solicitor, setting forth the nature of the injury or damage the claimant had sustained, and that was done. Plaintiffs being injured as they alleged, and as no doubt they were, served this notice upon the Minister and upon the Crown Solicitor. And then there was the proviso which said: "Provided always that nothing in this part contained shall affect or prejudice the right of any such claimant to maintain an action in the Supreme Court as he might heretofore have done in case the Minister shall deny any liability in respect of the matter of the claim for compensation." Now, in part 7 in section 147, paragraph 2, it was provided that "no plaintiff shall recover in any such action unless notice in writing have been given to the defendant twenty-eight days before such action is commenced of such intended action, signed by the attorney of the plaintiff, specifying the cause of such action." A number of other things were provided, none of which was done in this case. The requirements of the 147th section were taken to apply only to cases mentioned in the proviso of section 129, and the provisions which were to govern all actions were given in paragraphs 1, 2, and 3 of section 147; so that the 147th section referred it back to the proviso of the 129th section, and the proviso of section 129 referred it back to section 147, one referring to the other. Thus the requirement as to the mode of procedure applied only to those cases which were included in the proviso, and the proviso dealt only with cases where the Minister should deny his liability. Well, that was not the case here, because it was proved that there was no denial of liability, and the plea asserted that the Minister did not deny his liability in the matter; so, as a matter of fact, both by the evidence and by the pleadings, there was no denial; and therefore these requirements in the 147th section did not apply to this action. In this action it was not at all necessary that the plaintiffs should give twenty-eight days' notice, or fulfil any other of the requirements of the 147th section. The plaintiffs' case did not come within that section, as it was a case where there was not only no denial of liability but an admission of liability. That being so, what other case arose? In the 130th, 131st, and 132nd sections the Legislature pointed out what other course was to be taken where there was no denial of liability. Under the 130th section there was a provision that sixty days after the receipt of any notice of claim, a report and appraisement of the nature and amount of such injury or damage should be made, and that the claimaint should be informed as soon as practicable of the substance thereof by notice. The Minister did not fix the amount himself, but appointed a person to report, and, having obtained the report, communicated the substance to the person claiming. Then the 131st section provided that "if, within ninety days after the service of the notice of claim, the claimaint and the

Minister

Minister shall not agree as to the amount of compensation, the claimant shall be at liberty to institute proceedings in the Supreme Court in the form of an action for compensation against the Minister as nominal defendant." That might be the subject of more or less correspondence and interviews. It appeared in this case that there was a considerable amount of correspondence, and, unfortunately, by reason of the correspondence being without prejudice, and the parties not agreeing to have it before the Court, it did not come before them. However, there was a considerable amount of correspondence, which resulted in no agreement, there was no report, and the things which were contemplated by the 31st section were not done. All these things were required to be done where there was no denial of liability. Then section 132 provided the issue to be disposed of in reference to the report. Disposed of in what sort of case? Disposed of in a case where damage has been sustained, and the Minister did not dispute it, and admitted his liability. The issue to be tried was "whether the claimant was entitled to a larger sum by way of compensation than the amount so reported to the Minister, and notified to the claimant as aforesaid; and, if so, to what sum?" Now the issue there to be determined by the jury was, whether the plaintiff was entitled to a greater amount than the amount of the valuation made by the person to whom the question was referred by the Minister. If the plaintiff got a greater sum, the Minister paid the cost; and if it was a sum equal to or less than the valuation, the plaintiff paid the costs. An essential ingredient in the issue was as to the amount of the valuation. If there was no valuation, or reference to a valuator, what was the issue to go to the jury? It was idle to say, if they made no valuation, that it was equivalent to a refusal of compensation, because, if that were so, they would regard it as an intimation that nothing was to be paid, it would come under the 129th section. If it was a refusal to pay anything it would be a refusal to pay compensation, and then the 129th section would apply. But there was no refusal of compensation, and that being so the course to be taken was pointed out by the Act. The things which the Act required had not been done, and, therefore, he thought the defendant's plea was made out, and being a perfectly good one, and fully established, he thought the rule ought to be made absolute to set aside the verdict, and direct it to be entered for the defendant. No doubt there was a case here which was not provided for by the Act as it ought to have been—that was to say, that the Legislature did not appear to have contemplated the possibility, where there was a claim for compensation, of the Minister not setting the valuator in motion, as was the case here, and not taking steps to enable the plaintiff to set the sections of the Act in motion. It might be that a special action could be framed against the Minister for not obeying the Act, and putting plaintiff in a position to succeed, but with that they had at present nothing to do. Possibly a special action might be maintained under these sections, but that was not the action they had to deal with now. They had to deal with an action brought plainly and unmistakably under this Act, and, as the requirements of the Act had not been complied with, he was of opinion that the action could not be maintained.

Mr. Justice Faucett and Mr. Justice Innes concurred generally with the learned Chief Justice, and expressed an opinion as to the hardship inflicted upon plaintiffs owing to the Minister not having carried out the provisions of the Act in regard to valuation.

Rule made absolute to set aside verdict for plaintiffs, and to enter the verdict for defendant.

No. 20.

Minute from Engineer-in-Chief to Under Secretary for Public Works.

Sydney, 16 August, 1884.

Subject:—Re action Forsyth *v.* Wright—Reply to Crown Solicitor's letter of 8/8/84.

We are not prepared to admit the plaintiff's claim for compensation for damages in this matter as we do not think he has suffered any through our operations and cannot therefore suggest any sum to offer.

The 121st section of the Act states that "the Board shall before the commencement of any such operation cause a sufficient road to be made instead of the road to be interfered with, &c."

If the interpretation of the clause is to the effect that before the work is commenced a sufficient road in lieu of the one to be disturbed shall be made ready for traffic throughout the whole length to be operated on in contract before any work is done, then the Department has not carried out provisions of same, but if on the other hand it may be interpreted that before any section of road is opened up a sufficient length of substituted road shall be available for traffic in lieu of that interfered with, then the Department has fulfilled the conditions of the section.

If Messrs. Forsyth's claim for damages is entertained then all the business people on the same road have the same right of claim. To grant compensation in this case would be establishing a dangerous precedent and on principle the claim should be resisted.

W. C. BENNETT,
16/8/84.

No. 21.

A. Forsyth & Co. to The Secretary for Public Works.

Sir, Sydney, 2 September, 1884.

At the interview our Mr. Forsyth had with you yesterday we are afraid he failed to lay before you the matter properly as was intended. We will now endeavour briefly to do so.

The Metropolitan Water and Sewerage Act of 1880 provides two modes for assessing and recovering compensation for injury sustained by individuals through works carried out under the Act, namely, when liability by the Minister is denied, and when liability is not denied, by the Minister.

In the former case section 147 prescribes the mode of procedure, but as the Minister did not deny his liability redress under this section was closed against us.

In the latter case, when liability is not denied, sections 129, 130, 131, and 132 prescribe the course to be followed both by the Minister and the claimant. Section 129 prescribes that persons claiming compensation shall serve a notice on the Minister of the injury and damage claimed, and section 130 prescribes that the Minister shall within sixty days of the receipt of such notice (unless he denies liability) cause a report and appraisement to be made and inform the claimant of such appraisement. By section 131 it is provided that if the Minister and claimant should not agree as to the amount of compensation within ninety days from the date of the notice the claimant shall be at liberty to sue in the Supreme Court subject to the 132nd section. Now section 132 provides that the only issue to be tried is whether the claimant is entitled to a larger sum than the appraised amount.

Now as no appraisement has been made by the Minister (although we gave due notice according to the Act) this issue cannot be put and the second mode of assessing and recovering compensation is closed against us, through the Minister's non-compliance with the directions of the Act as to appraisement. Now we respectfully submit you are in duty bound to carry out the law and have an appraisement made, to enable us to have this question settled by agreement or tried on its merits by law.

You will no doubt consider it your duty to ask Mr. Bennett to report on this matter, but we respectfully submit that as the works by which we sustained the injury were carried out by him in such

a way as to cause the injury it cannot be expected that he will report in our favour and against himself and his department, and that at this stage the question has gone beyond his department into that of the Minister or Ministry.

We have, &c.,
A. FORSYTH & Co.

I should like the Crown Solicitor to take counsel's opinion as to the liability of the Crown to be cast for damages in this case if the plaintiff should take the proper course in law?—F.A.W. Crown Solicitor, B.C., 4/9/84.—J.R.

No. 22.

A. Forsyth & Co. to The Secretary for Public Works.

Sir, 339 Kent-street, Sydney, 30 June, 1885.

Having called on the Under Secretary for Public Works a great number of times during the last four weeks with reference to our claim against the Government for compensation for the injury sustained by us during the construction of the sewer in Bourke-street, Waterloo, by your Department, and as Mr. Rae states that the papers sent in by us cannot be found, we herewith enclose copy of letter sent
See No. 19: in to you on 2nd September, likewise *S. M. Herald's* report of the trial before the Full Court. There was a previous letter sent in to the Department in August more fully setting out the circumstances of the case which has been mislaid, but with the exception that the letter asked the Government to refund the costs of the trial in the Supreme Court paid by us—and this request was withdrawn at the interview we had with you on 1st September; both letters are substantially to the same effect.

You will see from the Judge's decision that we got a verdict for £700, and that this verdict was entered for the defendant on the ground that as no appraisement was made there was no issue to go before the jury under the Act.

We have, &c.,
A. FORSYTH & Co.

No. 23.

A. Forsyth & Co. to The Secretary for Public Works.

Sir, 339 Kent-street, Sydney, 2 September, 1884.

At the interview our Mr. Forsyth had with you yesterday we are afraid he failed to lay the matter properly before you as was intended. We will now endeavour to do so.

The "Metropolitan Water and Sewerage Act of 1880" provides two modes for assessing and receiving compensation for injury sustained by individuals through work carried out under the Act, namely, when liability is denied, and when liability is not denied, by the Minister.

In the former case (when liability is denied) section 147 prescribes the mode of procedure, but as the Minister did not deny his liability, redress under this section was closed against us.

In the latter mode (when liability is not denied) sections 129, 130, 131, 132, prescribe the course to be followed both by the Minister and the claimant. Section 129 prescribes that persons claiming compensation shall serve a notice on the Minister of the injury and damage claimed, and section 130 prescribes that the Minister shall within sixty days after the receipt of such notice cause a report and appraisement to be made (unless he denies liability), and inform the claimant of such appraisement. By section 131 it is provided that if the Minister and claimant should not agree as to the amount of compensation within ninety days from the date of the notice, the claimant shall be at liberty to sue in the Supreme Court subject to the 132nd section of the Act. Now section 132 provides that the only issue to be tried is whether the claimant is entitled to a larger or smaller sum than the appraised amount.

No appraisement having been made by the Minister, although we gave due notice according to the Act, the issue cannot be put and the second mode of assessing damage and recovering compensation is closed against us, through the Minister's non-compliance with the directions of the Act as to appraisement.

Now we respectfully submit you are in duty bound to have an appraisement carried out to enable us to have this question settled by appraisement or tried on its merits before the Supreme Court.

You will no doubt consider it your duty to ask Mr. Bennett, Chief Engineer for Sewers, for his report on this matter, but we respectfully submit that at this stage the case has gone beyond the range of his Department. The works by which we sustained this injury were carried out by him in such a way as to cause this injury. It cannot be expected that he will report in our favour and against his Department; it is now a question for the Minister or the Ministry.

We have, &c.,
A. FORSYTH & Co.

Minute from Under Secretary for Public Works to Engineer-in-Chief.

Department of Public Works, Sydney, 8 July, 1885.

Forsyth and Co.'s claim for damage, Bourke-street sewerage works.

WHAT does Mr. Bennett recommend to be done? Mr. Forsyth, for an appraisement to be made of the damage to enable him either to accept the award or appeal to the Supreme Court? J.R.

Previous paper, 84/5/77, was forwarded to Under Secretary on 1/9/84 for transmission, I believe, to Crown Solicitor.—F.C.P., 9/7/85. Engineer-in-Chief for Sewerage. I never saw the paper from Mr. Forsyth stated by C.S. to have been withdrawn by Mr. Forsyth.—W.C.B., 9/7/85. Under Secretary. Submitted, 10/7/85. But what does Mr. Bennett recommend?—J.R., 10/7/85. Whatever the Crown Solicitor thinks advisable, I think the original claim should be resisted; as to the claim for costs Crown Solicitor is the best judge.—W.C.B., 10/7/85. Under Secretary, B.C. Crown Solicitor's advice had better be obtained.—F.A.W., 14/7/85.

No. 25.

No. 25.

Forsyth & Co. to The Honorable F. A. Wright.

(Private.)

Dear Sir, Sydney, 5 August, 1885.

I received a communication last week from the Department of Public Works *re* Bourke-street sewer. It states the Government will resist our claim for compensation, and are prepared to defend any action we may bring.

I do not know if this statement applies only to an action at law, or whether it is intended to go behind the understanding arrived at at our chance meeting in Bathurst-street last week. If the former, we will take the necessary steps to carry out the matter as understood at our meeting; if it is to be taken in the latter sense it will be useless to address your Department any further. Will you please give us an early answer.

Yours truly,

A. FORSYTH.

For my successor, waiting opinion from Crown Law Officer.—F.A.W., 6/11/85. Prepare *précis* of case.—J.R., 14/11/85. Done, 16/11/85.

No. 26.

Précis of case.

Messrs. Forsyth and Co.'s claim *re* Bourke-street sewer.

Department of Public Works, Sydney, 16 November, 1885.

Messrs. A. Forsyth and Co. brought an action against the Government for compensation for alleged damage to property by reason of the Bourke-street sewer works, and a Supreme Court jury awarded them £700 damages, but in consequence of an erroneous course of proceeding having been adopted by them of their own motion the verdict of the jury was set aside and the same entered for the defendant. They subsequently asked that the Government pay the costs of the action (which the Crown Solicitor thinks should be rejected) and also award them compensation, to which the Commissioner for Roads decidedly objects. Messrs. Forsyth and Co., on the 5th August last, refer to some conversation which took place between the late Secretary for Public Works (Mr. Wright) and Mr. Forsyth, the purport of which, however, is not disclosed.

J.R.

Submitted, 16/11/85.—J.R. For my successor.—W.J.L., 17/12/85. Re-submit end of December. Submitted, 4/1/86.—J.R.

Sydney: Thomas Richards, Government Printer.—1886.

1885–6.

LEGISLATIVE ASSEMBLY.

NEW SOUTH WALES.

MESSRS. A. FORSYTH & CO. *v.* MINISTER FOR PUBLIC WORKS.

(FURTHER PAPERS.)

Ordered by the Legislative Assembly to be printed, 4 August, 1886.

FURTHER RETURN to an *Order* made by the Honorable the Legislative Assembly of New South Wales, dated 30th June, 1886, That there be laid upon the Table of this House,—

"Copies of all papers, letters, reports, minutes, and other documents, relating to the claim for compensation, and the action-at-law thereon, made by Messrs. A. Forsyth & Co. against the Minister for Public Works, tried in the Supreme Court in August, 1884."

(*Mr. Forsyth.*)

Minute from Under Secretary for Public Works.

Messrs. Forsyth and Co.'s claim *re* Bourke-street Sewer.

Department of Public Works, 16 November, 1885.

MESSRS. A. Forsyth and Co. brought an action against the Government for compensation for alleged damage to property by reason of the Bourke-street sewer works, and a Supreme Court jury awarded them £700 damages, but in consequence of an erroneous course of proceeding having been adopted by them, on their own motion the verdict of the jury was set aside, and the same entered for the defendant. They subsequently asked that the Government should pay *its costs of the action (which the Crown Solicitor thinks should be refused) and also award them compensation to which the Commissioner for Roads decidedly objected.

Messrs. Forsyth & Co. on the 5th August last refer to some conversation which took place between the late Secretary for Public Works (Mr. Wright) and Mr. Forsyth, the purport of which is not disclosed.

J.R.

The Under Secretary for Public Works to Messrs. Forsyth & Co.

Gentlemen, Public Works Department, Sydney, 27 July, 1885.

Referring to the correspondence respecting the costs incurred by you in your action against the Government, and also again asking compensation for injuries alleged to have been sustained by the Bourke-street sewer, I am directed to inform you that your claim for the costs referred to cannot be admitted. I am to add that the Government will resist your claim for compensation, and are prepared to defend any action you may be advised in the matter.

I have, &c.,
JOHN RAE.
