43 and 44. In the south of France, where, as already stated, the system of canal management is similar to that now proposed, it is found that the local associations, through either ignorance or carelessness, frequently allow irrigation works to fall into such disrepair as to cause waste of water and interfere with the efficiency of the works. This and other kindred evils are intended to be here provided against.

cancel the constitution of the said Trust, and may place all or any of the rivers, streams, creeks, lakes, and underground supplies of water within the district in which such works are situated under the immediate charge of the Board, to be managed and administered under this Act.

PART IV.—District Administration—Local Water Trusts.

Formation of Water Trusts.

45. Whenever the owners, lessees, and occupiers of land desire to combine for the purpose of constructing works for the conservation or utilization of water, or for drainage of land, a petition, signed by at least five of such owners, lessees, or occupiers, and setting forth the nature and extent of the works desired by the said owners, lessees, and occupiers, and the quality and extent of the land likely to be benefited by such works, shall be submitted to the Board by the said owners, lessees, and occupiers.

Board to inquire into propriety of forming Trusts.

46. The Board shall, without delay, investigate and inquire into the feasibility and propriety of the proposed works; and if after such investigation and inquiry the said Board shall deem it right and expedient that a Trust shall be formed for the survey, construction, maintenance, and administration of works for water conservation and utilization, or for drainage, the said Board shall, subject to the sanction of Government, order the appointment of the said Trust, and shall assign a name to the said Trust, and shall describe the boundaries of the district to which the jurisdiction of the said Trust shall extend, and shall define the limits of the water supply which such Trust shall be entitled to use and administer.

Formation of Water Trusts to be notified publicly.

47. The constitution of a Trust shall be publicly notified in the Government Gazette, and in at least one newspaper circulating in the district of the said Trust, and such notification shall state briefly the boundaries and name of the said Trust, and the number of representative members, and the names of the persons qualified to vote for members of the said Trust, and the date on which the first election of members of such Trust shall take place.

Boundaries of Trust District how decided.

48. In deciding the boundaries of Water Trusts the Board shall be guided by watershed lines, and by the position of rivers and other natural sources for water supply; and the Board shall, wherever practicable, arrange the boundaries of Trusts in such manner as to include one or more complete catchment areas.

Procedure of Board when organizing a Trust.

49. When making preliminary investigations and inquiries regarding the formation of any Water Trust, the Board shall prepare, or cause to be prepared, a list of the owners, occupiers, and lessees of land within the boundaries of the proposed Trust District; and this list must show the nature of tenure, the area, and the quality of the land held by each owner, occupier, and lessee in the said proposed Trust District. By means of this list the names of all persons entitled to vote for members of the said Trust and the numbers of votes which every such person will have a right to give will be determined.

Members of Trusts

50. The conservation and utilization of water, and the drainage of every Trust District, shall be managed and administered by members of the said Trust, who will be elected from time to time by the owners, lessees, and occupiers of land and the owners of miners' rights and leases within the said Trust District, and the number of members thus elected in every Trust shall be not less than three or more than nine.

Qualification of Trust representation.

51. In the Western Division of New South Wales, as constituted by the Land Act of 1884, every representative member of a Water Trust must either be owner of not less than 640 acres of land or lessee or occupier of not less than 10,000 acres. In the Central Division, as constituted under the same Act here mentioned, every representative member of a Water Trust must either be owner of not less than 160 acres of land or lessee or occupier of not less than 2,560 acres. In the Eastern Division, as constituted by the same Act here mentioned, every representative member of a Water Trust must either

NOTES AND EXPLANATIONS.

Notes and Explanations regarding PART IV.

In the Victoria Water Conservation Act of 1881, Part VII is devoted to powers conferred on private individuals. It appears to us that this part of the question could be better dealt with by making the definition of "Trust" more elastic, and including within the same regulations and the same administrative system all Water Trusts, however extended and however limited. All the regulations for Trusts here proposed are framed so as to suit Trusts whether large or small, and whether the water be conserved for and distributed to irrigation works, or to graziers, or to miners.

Procedure in constituting Trusts.

45 to 48. In these sections the procedure followed when constituting a Water Trust is detailed. In framing the proposed regulations the Victorian legislation has been only partially followed, as in some cases it is not applicable, and in others not sufficiently concise. The fixing of boundaries of Trust Districts here dealt with is a matter requiring judgment and care. The principle on which alone the boundaries can satisfactorily be dealt with is to follow the natural boundaries, that is, the ridge and valley lines, and not any artificial boundaries which have been fixed for municipal or other purposes.

Qualifications of members and of voters for Trusts.

49 to 54. These paragraphs deal with the qualifications of members and of voters for Water Trusts, and the main principles on which they are founded are those accepted in recent Acts to extend local government. It may be mentioned that the Victorian Water Conservation Act of 1881 orders that the appointment of Water Trust Commissioners shall rest with Municipal Councils. We entirely fail to see the propriety of such a course, and think that Water Trusts and Municipal Councils should be regarded as two entirely separate bodies, each dealing with the other as it would with a private individual or a private company. On the other hand, there is no reason why a municipal councillor should not also be member of a Water Trust, and no regulation is proposed which would be inimical to such an arrangement. The principle now advocated is, briefly, that members of Water Trusts should be elected by and from those interested in the equitable and economical distribution of the available supply.

be the owner of not less than 40 acres of land or the lessee or occupier of not less than 640 acres.

Qualifications of voters.

52. For the election of members of Water Trusts the owner, lessee, or occupier of not less than 1 acre or more than 640 acres shall have one vote for every vacancy; the owner, lessee, or occupier of more than 640 acres, and not more than 2,560 acres, shall have two votes for every such vacancy; the owner, lessee, or occupier of more than 2,560 acres, but not more than 10,000 acres, shall have three votes for every such vacancy; the owner, lessee, or occupier of more than 10,000 acres shall have four votes for every such vacancy.

Formation of Mining Trusts.

53. Wherever it is found impracticable for any Local Trust to deal with the mining and manufacturing interests within its district the Government may, on the recommendation of the Board, authorize the formation of Special Water Trusts for mining or manufacturing purposes only. The qualification for the representative membership of every such Trust shall be the registered possession of a mineral or special lease, and the qualification of voters in such Trust shall be the registered possession of a miner's right.

Method of recording votes.

54. The Secretary to a Water Trust, or other person authorized by such Trust or by the Board, shall, as soon as possible after the notification of the Constitution of such Trust, transmit by post or otherwise to every voter residing at a distance of more than ten miles from the nearest polling place a printed or written or partly printed and partly written ballot-paper containing the names of all the candidates qualified for the office of representative members; or if such voter have a right to more than one vote, then the number of ballot-papers supplied to the said voter shall be equal to the number of votes to which he is entitled. Votes should be recorded on the papers according to prescribed regulations, and every voter should sign all his voting papers and return them to the Secretary to the Trust in a cover stamped with the words "Voting Papers." Such covers will be transmitted free of charge by post, and shall, in every way, be treated as registered correspondence. Qualified voters residing within ten miles of a polling-place shall record their votes by ballot in the manner prescribed for Municipal Elections. The names of the Trust representatives so elected shall be notified in the Government Gazette, and in at least one newspaper circulating in the said Trust district.

Procedure on election of Trust representatives.

55. Within one month after the election of members of a Water Trust the said members shall meet at some convenient time and place to be sanctioned by the Board, and at that meeting, or at an adjourned meeting, the said members shall elect a Chairman, and shall transact such business as may be brought before them; and such members shall thereafter meet and adjourn as they think proper from time to time and from place to place. A special meeting of the members of any Water Trust may at any time be called, on the requisition of the Board or of the Chairman of such Trust, or on the requisition in writing of any two members of such Trust, addressed to the Chairman or Secretary of the said Trust.

Power to rest only with quorum of members.

56. All powers vested in a Water Trust may be exercised by such Trust at any meeting held in pursuance of this Act at which there is a quorum of the members present, but not otherwise.

Number required to form a quorum.

57. Whenever there is an even number of members in any Trust a quorum shall consist of not less than half the members of such Trust. When there is an odd number of members in any Trust the smallest number constituting a quorum will be half of the number obtained by adding one to the number of members.

Power of Board to alter number of members or quorum.

58. The Board, subject to the sanction of the Government, shall have power to alter the name of any Trust, or the number of members of any Trust, and also to alter in any Trust the number of members required to form a quorum.

Power to postpone or adjourn meetings.

59. If at any meeting of a Water Trust there be not a quorum present within half-an-hour after the time appointed for such meeting, then it shall be lawful for the members present, or the majority of them, or any one member, if only one be present, to adjourn such

55 to 62. The details of the system of procedure of meetings of local Trusts is based on the New South Wales Municipalities Act and the Victorian Act for the Conservation and Distribution of Water, but are arranged to suit the altered circumstances of Water Trusts. Procedure at meetings of Trusts.

meeting until another hour or another day; and if no member be present, then it shall be lawful for the Secretary to adjourn the proposed meeting till another hour or another day.

Members not to be paid.

60. No member of any Water Trust shall be the holder of any paid office or situation under the said Trust, nor receive any salary, emoluments, or expenses of any kind from the said Trust unless with the special sanction of Government and with the recommendation of the Board.

Members not to be contractors.

61. No member of any Water Trust shall tender for, obtain, or hold any contract or any part or share in any contract for works or surveys under the charge or authority of such Trust.

Penalty for illegally acting as members.

62. Every person who, being incapacitated or not duly qualified to act, or having become disqualified from acting as member of a Water Trust, is present at a meeting of the members of such Trust, and acts thereat as a member shall, for every meeting on which he is so present and acting, be liable on conviction thereof before any two Justices to a penalty not exceeding £50.

Trust to be a body corporate.

63. Every Water Trust shall be a body corporate, and shall, subject to the sanction of the Board, have power to purchase and hold lands, tenements, and hereditaments and other property for the purposes of this Act. It shall also, under the same conditions, have the power to sell, exchange, or let on lease the whole or any portion of such lands or other property for the benefit of such Trust.

Powers delegated by Board.

64. Subject to the sanction of Government, the Board may delegate to any Water Trust all or any of the right, power, and authority of the said Board to hold, use, and administer the rivers, streams, creeks, lakes, springs, and other sources of water supply situated within the boundaries of the district included within the jurisdiction of such Trust.

Powers of Trusts.

65. Subject to the sanction of the Board, every Water Trust shall have and exercise, for the purposes of this Act, all the powers given herein to the Board in sections 29, 31, 35, and 36.

Right of appeal.

66. The owners, lessees, or occupiers of land, or other persons affected by any action taken in regard to water conservation and utilization, or to drainage, or by any neglect to take action in regard to such works, shall make application for redress to the Local Trust, or, in the absence of a Trust, to the Board, and shall have a right to appeal to the Board against any decision of a Trust, and to the Minister against a decision of the Board.

Tenure of office by members.

67. In every Water Trust which consists of an even number of members, one more than half the number of members elected on the formation of the Trust shall hold office for three years, and the remaining members for two years. In any Water Trust which consists of an odd number of members, half the number obtained by adding one to the authorized number of members shall be the number which will hold office for three years, and the remainder shall hold office for two years. At the first election of members for any Water Trust the elected members shall be placed in order according to the number of votes received by each. The members who have obtained the higher number of votes shall, to the number hereinbefore described, be declared elected for three years, and the remaining members for two years; but as vacancies arise the members elected to fill them shall in all cases be elected for three years, and outgoing members may be re-elected if otherwise eligible. The members shall elect from among their number a Chairman, to preside at the meetings of the said Trust. The said Chairman shall have the same right as other members of the Trust to vote on all questions which are brought before the said Trust, and if in any case the number of votes for and against any matter before the said Trust be equal the said Chairman shall, in addition to his ordinary vote, have the right to give a casting vote. The tenure of the office of Chairman of every Water Trust shall not be for more than one year, and shall in all cases terminate in the month of December, but the members of any Water Trust may re-elect a Chairman on the expiration of his term of office.

NOTES AND EXPLANATIONS.

Water Trusts to be corporations.

63. In declaring every Water Trust to be a corporation, the precedent of the Victorian Act (No. 716) of 1881 has been followed, but in any case the necessity for this provision is evident.

Making over charge of rivers and other sources of supply to Trusts.

64 and 65. The arrangement here adopted of making over charge of the rivers, streams, lakes, and other natural sources of water supply to Water Trusts, to be held by them on behalf of Government, and under the directions of the Board, is one of primary importance. While it is an accepted rule in almost every country that all such natural sources of water supply belong to Government, it is also unfortunately a state of affairs common to several countries that the Government rights in natural sources of water supply have suffered seriously, or been altogether lost, through neglect to define and maintain them. It is a vital principle of the Act now proposed, that not only should the rights of the State be clearly set forth, but that the protection and perpetuation of those rights should be ensured. In Colorado and California the right of the State to the water supply was at one time admitted, but in both this right appears to be almost entirely lost or alienated.

Constitution and management of Trusts.

67, 68, and 69. These sections, relating to the details of the constitution and management of Trusts, require no comment.

Election of temporary Chairman.

68. In the absence of the Chairman from any meeting a majority of the members present may elect one of their number to act as Chairman for that meeting only.

Regulations regarding compensation for land.

69. The regulations herein directed for the settlement of claims for compensation where any damage is done or loss occasioned to any owner, occupier, or lessee of land or tenements of any kind, through the prosecution of surveys or other investigations by the Board, shall apply also to damage done or loss occasioned by any Water Trust in the administration of this Act.

Power of Trusts to employ engineers and others.

70. Whenever the members of any Water Trust have reason to believe that works for the conservation and utilization of water can be carried out with profit in their district they may, subject to the sanction of the Board, employ qualified engineers and surveyors and any others necessary for the preparation of the surveys, designs, and estimates for such works.

Sanction of Central Board required for all works.

71. No local Trust shall have power to carry out any works for water conservation and utilization without the sanction of the Board.

Power of Trusts to act in cases of emergency.

72. But whenever there is reason to apprehend that damage may be caused by floods before a reply could be obtained from the Board, or whenever there is an opportunity to conserve flood-water, which opportunity might be lost before a reply could be received from the Board, any Water Trust may, on its own responsibility and at its own risk, deal with the necessities of each such case as it may deem proper. In every such case the Board should without delay be informed of the case in detail, and the sanction of the said Board should without delay be applied for.

Power of Trusts to make by-laws.

73. When works for the conservation and utilization of water are administered by any Trust, such Trust shall have the power, subject to the sanction of the Board, to make by-laws for the maintenance and management under this Act of such water supply; and if any person or persons neglect or refuse to obey the said by-laws, the supply of water given to such person or persons may, after warning has been given, be stopped till the said by-laws are properly observed.

Water-rights not to be transferable, except by sanction of Trusts.

74. No person supplied with water by any Trust shall have a right to transfer such supply or any portion of it without the sanction of the Trust. In all receipts for water-rates paid to Trusts, and in all papers and documents referring to rates, a note shall be entered that the said water-rights are not transferable except with the sanction of the said Trust.

Water supplied by Trusts to be used only in manner sanctioned.

75. All supplies of water provided by local Trusts shall be delivered subject to this Act and to the by-laws; and no person shall have a right to convey or use such water in a wasteful manner different to the terms and regulations ordered in this Act, and prescribed by the said Trust with the sanction of the Board.

By-laws must be approved by the Board.

76. The by-laws proposed for the regulation of details under Trusts must in every case receive the sanction of the Board before they can be put in force.

Right-of-way for water.

77. Any Water Trust may acquire by purchase or lease a right-of-way for water through any land, whether it belong to private individuals or to corporations or to Government. If a right-of-way for a drain or distributary or channel of any kind be required by any person from any Trust, or from the Board, to enable him to obtain a supply of water, or for the purposes of drainage, the Government may, on the recommendation of the Board, resume a right-of-way for such water supply; and the rules under which compensation is regulated for any land resumed for works carried out by the Board, or by Trusts, shall apply to all water-ways and lands for the passage of water so resumed.

78. Under no circumstances shall the passage of water through the land of any owner, occupier, or lessee confer on such owner, occupier, or lessee any right or title or vested interest in such water.

Trusts not liable for failure of supply.

79. If a Trust in charge of the administration of any canal, channel, or water supply of any kind fail to furnish the established

NOTES AND EXPLANATIONS.

Powers conferred on Trusts.

70 and 71. These sections further define and limit the powers which may be delegated by the Board to Trusts.

Power of Trusts in cases of emergency.

72. The principle of this section, regarding the power of Trusts to deal, on their own responsibility and in anticipation of the sanction of the Board, with works of emergency, is borrowed from the Spanish Law of Waters, which has a corresponding clause.

Intention of by-laws.

73. It is here intended that these by-laws should include rules suitable to the Trust District in which they are in force. It is anticipated that entirely different conditions will exist in different Trusts, and the course proposed is to have a comprehensive Act which will include all, while the by-laws framed in accordance with this Act will suit each individual case.

Necessity for Government to maintain complete control over the water supply.

74 and 75. Unless the Government maintain complete control over the water supply, vested interests of a troublesome nature are certain to be acquired. It is also necessary not only that the quantity supplied to every person shall be decided by the Trust, but also that the means and method of using the supply shall be approved. On this point the practice in India, and particularly in the North-west Provinces, is very stringent, and it is the immediate result of experience derived from Southern Europe. In the case of the Lower Ganges Canal, one of the most recently constructed in India, the greatest care was taken in fixing the position of irrigation outlets; the nature of the soil, the inclination of the ground, and the general features of the neighbourhood being in every case taken into account. No outlet was allowed where the water would run through soil impregnated with salts, nor where there was likely to be much loss by percolation.

76. This rule requires no comment.

77 and 78. In connection with the distribution of water for irrigation and other purposes, one of the most important points to secure is the right to obtain a passage for water through any land between the source of supply and the place where the water is to be used: it is necessary, to guard against the chance of individual caprice or ill-will being allowed to prevent the execution of useful work. It should be remarked that it is specially provided that the Water Trusts, and not the individuals directly interested, acquire the strip of land or the right-of-way required for a channel. It is specially intended by this arrangement that the public interest and property in the water should be secure in every detail.

79. Provision is here made against liability for damages in case of failure of the supply. The Trusts are left responsible for damage done by any neglect of their members.

quantity of water, or the quantity required by the user of any watercourse or irrigation channel, the said Trust shall not be liable for any damage so arising if such failure of the supply was due to causes beyond the control of the said Trust.

Right-of-way for water across roads.

80. The right-of-way for water, as described in section 67, applies also to the right to cross public or private roads and public or private watercourses.

Bridges or culverts to be built at road-crossings.

81. Wherever it is necessary to construct a canal or channel of any kind, or to divert a supply of water across any road or watercourse, a suitable bridge or culvert or other means of crossing without hindrance to the traffic on the said road must be constructed.

Water to be sold by measure.

82. In the management of water supply every Trust shall, as far as practicable, sell the water by measurement. The appliance for or means of measurement must be approved by the Board.

Regulations for economical use of water.

83. Wherever water for irrigation is not sold by measure, the Water Trust shall have power to regulate in its by-laws the manner in which the land proposed to be irrigated shall be prepared for cultivation, and the manner in which water is used for mining and manufacturing purposes.

Power of Trusts to fix rates.

84. Subject to the sanction of the Board, every Trust shall have power to fix rates for water supplied, or on account of land benefited by drainage works. The rates for water shall ordinarily be of three kinds: first, for domestic use, and for watering and washing stock; second, for irrigation; third, for water power. In addition to these rates, Trusts may fix a rate per acre on land benefited by drainage works; and Trusts may also, when measurement of water for irrigation is not practicable, fix rates per acre for different kinds of crop grown. Also, where it is not practicable to measure water used by stock, a Trust may fix rates for every kind of stock to which water is supplied.

Regulations to be observed in fixing rates.

PART V.—Loans—how sanctioned, incurred, and repaid.

Procedure when a loan is required by a Trust.

85. Whenever the representatives of a Water Trust desire to raise money on loan for the construction of any works for water conservation or drainage, such Trust representatives shall make application to Government, through the Board, setting forth in their application full particulars regarding the nature and extent of the works proposed, and of the land to be benefited.

Inquiry previous to sanction of loan.

86. After a full inquiry regarding the statements contained in such application, the Board shall report to the Government, and shall make such recommendations respecting the said application as it may deem just.

Power of Government to grant or guarantee loans.

87. On receipt of such application and recommendation the Government may temporarily advance funds to such Trust, or it may sanction the raising of a loan by the said Trust, and may guarantee the payment of interest on such loan.

Trusts prohibited from raising loans without sanction.

88. It shall not be lawful for a Water Trust constituted under this Act to obtain money on loan from any source, or for any purpose, without previously obtaining the sanction of Government.

Security on which loans can be raised

89. Loans required by Water Trusts shall, when sanctioned, be raised on the security of the rates leviable on the lands benefited, or to be benefited, by the works carried out, or proposed to be carried out, or on the security of the lands and works belonging to such Trusts.

Purposes to which rates are to be devoted.

90. Wherever a Trust has carried out works with the aid of a loan, the rates levied by such Trust from the persons benefiting from such works shall be used as follows—that is to say:—

(*a*) For payment of interest of the loan.
(*b*) For the maintenance, repairs, and management of the said work.
(*c*) To contribute to the sinking fund.
(*d*) For the useful extension and development of the works.

80. and 81. The necessity for these clauses is obvious.

82, 83, and 84. The necessity and importance of the first and last of these clauses is evident. In the case of section 83, it may be explained that careless cultivation is one of the most fruitful sources of waste of water in irrigation. It is necessary therefore to provide some check on the manner in which the water is used. In India the land for irrigation has to be divided into rectangular plots, the areas of which are fixed by local regulations.

Notes and Explanations regarding PART V.

Sections 85, 86, and 87 conferring powers to raise loans for carrying out works for water conservation, or for drainage, are intended to ensure that loans will be sanctioned only for works which may be depended on to prove satisfactory.

Section 88 is in accordance with the Municipalities Act of this Colony, which directs (clause 190) that "no money shall be borrowed except with the sanction of the Governor." Municipalities Act of 1867.

Section 89 is almost identical with clause 29 of the "Victorian Water Conservation Act of 1883." Act 778 of Victoria 1883.

Section 90 is similar to clause 60 of the Victorian Act last quoted.

Limit to the total amount of loans.

91. When the representatives of any Trust make application for a loan, or for permission to raise a loan, and furnish to the Board the information required in this Act regarding the nature and extent of the land to be benefited, the Board shall cause an estimate to be made of the value which such land and other property will possess on the completion of the proposed works. The total amount of the liabilities of a Trust shall not be permitted to exceed two-thirds of the enhanced value thus estimated, which the land and other property benefited will possess on the completion of the works for which the loans are raised.

Change of names or boundaries of Trusts not to affect agreements.

92. If, after due consideration, and with the sanction of Government, the boundaries of any Trust District, or the name of any Trust, be altered, no bond, mortgage, or agreement entered into by such Trust previous to such alteration shall be rendered invalid, or shall be in any way affected by such alteration.

Points to be specified in applications for loans.

93. In every application to Government for a loan or for permission to raise a loan Local Trusts shall specify the rates proposed to be levied by them, the rate of interest to be paid, the amount which will annually be credited to a sinking fund, and the number of years for which the loan is required; and in no case shall the Government have power to grant or authorize a loan unless the proposals on all these points are deemed satisfactory.

Borrowing in excess of amount sanctioned —how dealt with.

94. If, in contravention of this Act, any Trust shall borrow money without the sanction of Government, or in excess of the amounts sanctioned by Government, all the members of such Trust who have consented to the borrowing of such money shall be jointly and severally liable to pay the same, together with all interest thereon, to the persons from whom the same was borrowed, and the same may be recovered from such members in any Court of competent jurisdiction, but in no case shall such money be recoverable from the Trust District; and if any appropriation of moneys belonging to the Trust be made for the purpose of liquidating any claim for money so borrowed, such members of such Trust who have consented to the misappropriation of money for that purpose shall be jointly and severally liable to refund the same and all interest thereon, and the same may be recovered from such members of such Trust, or any of them, and may be sued for by any ratepayer of the Trust District.

Separate accounts to be maintained for every loan.

95. Every Trust shall keep a separate account for every loan incurred by it, and such accounts shall at all times be accessible to the Board or to any officer deputed by the Government to inspect them; and copies or abstracts of such accounts shall be submitted to Government in such manner and at such times as Government may direct.

Misappropriation of loans.

96. Under no circumstances, except by the sanction of Government previously obtained, shall any Trust apply any portion of a loan to a purpose other than that for which the said loan was raised; and if, in contravention of this Act, any Trust misappropriates a loan or any portion of it, the members of such Trust who consent to such misappropriation of funds shall be jointly and severally responsible for the repayment of such funds, together with interest, as described in section 91.

PART VI.—Drainage Works.

Powers granted regarding water conservation to extend to drainage.

97. The powers herein conferred on the Government and on Local Trusts to enter on, survey, and resume lands, and to undertake, construct, and maintain works for the conservation and distribution of water, shall also extend to projects and works for the drainage of land.

Procedure regarding drainage works.

98. Whenever it shall appear to the Board or to a Water Trust that works for the drainage of any land are required in the interests of the public, the said Board or the members of the Water Trust within whose district such land is situated may, with the sanction of Government, proceed to make investigations and to prepare surveys, designs, and estimates for such works, in the manner herein described in

NOTES AND EXPLANATIONS.

Section 91 contains an important principle regarding the manner in which the maximum amount which a Trust may be allowed to borrow should be estimated. There are cases in which works for water conservation would raise the value of land tenfold, and it would clearly be short-sighted in such cases to estimate the borrowing powers of a Trust on the basis of present value. The justice of the principle of fixing the maximum borrowing powers of local bodies according to the enhanced value anticipated as a result of proposed works has already been recognized by the Crown Law Officers of this Colony.

Section 92 is based on provisions made in the most recent amendment of the Victorian Water Conservation Act for the effect of changes of names of Trusts. Act 829 of 1884—Victoria

Section 93 is intended to indicate the points connected with the financial prospects of any project which a Trust will be required to prove satisfactory before a loan can be sanctioned.

Section 94 is almost identical with clause 57 of the Victorian Water Conservation Act of 1883, and its importance is obvious. Act 778 of 1883—Victoria.

Sections 95 and 96 are based on clause 54 of the Act last quoted.

Notes and Explanations on PART VI.

Sections 97 and 98 are intended to confer the same powers in regard to drainage works as those already conferred in regard to works for water conservation.

connection with works for water conservation. The Board or the said Water Trust may also construct such works, and for this purpose may levy rates and raise loans.

Project to be submitted to the Central Board.

99. Before a Trust can be permitted to carry out any drainage work, a statement must be furnished to the Board showing the nature and extent of the land which will be benefited by the proposed works, and setting forth clearly the value of such land and the extent to which it will be benefited. This statement of the anticipated results of the proposed works, together with the plans and estimates, must be approved by the Board before such works can be sanctioned.

Assessment of rates.

100. In assessing rates on lands benefited by drainage works the members of Water Trusts shall be guided by the proportionate extent of the increase in value due to such works.

Combined drainage and water conservation works.

101. Wherever drainage works are constructed by the Board, or by a Water Trust, the drainage water thus made available shall, as far as practicable, be conserved and utilized; and no designs for drainage works shall be sanctioned unless the conservation of the drainage water is considered fully, and as far as practicable provided for.

Assessment on combined works.

102. When drainage and water conservation are provided for in the same project the rates for such works shall be assessed both on the lands drained and on the lands benefited by the water supply so provided.

Works aided by loans to be subject to Government sanction.

103. Drainage works proposed to be carried out with the aid of loans must be first sanctioned by Government, and must be subject to Government inspection and approval.

Projects for water conservation to be considered in relation to their effect on drainage.

104. When any project for irrigation works, or for works for water conservation, is submitted to the Board by a Local Trust, the Board shall consider such project in relation to its bearing on drainage; and if it shall appear to the Board that such project should, either on sanitary grounds or to prevent injurious effects to the land, include provisions for a system of drainage, the Board shall require that such provision shall be made in the design and estimate for the proposed works.

Tail water from mines and manufactories.

105. When the use of a supply of water for mining or manufacturing purposes is granted by any Trust, such use shall in all cases be subject to the provisions of this Act in regard to waste or to use in a negligent manner; and every person using a supply of water for mining or manufacturing purposes shall be required to make such arrangements as will render such supply of water available for further uses as far as it is practicable to do so.

PART VII.—Navigation.

Trusts to regulate navigation within their own districts.

106. When the whole or any portion of a navigable river is situated within the bounds of a Trust District the Government may, on the recommendation of the Board, delegate to such Trust the authority to regulate the navigation within such district.

Authority of Trusts to carry out projects or works for navigation.

107. In pursuance of this authority, any such Trust may make surveys, designs, and estimates for works connected with the improvement of navigation, and may for such purposes exercise the same power and authority as herein authorized for projects or works for water conservation.

Navigation to be provided for as far as advantageous.

108. In all cases where works for water conservation and supply interfere, or are likely to interfere, with the level or flow of water in any river, the requirements of navigation may be provided for, so far as this can be done, without detriment to the interests of water supply and irrigation.

Regulations for preparing navigation projects to be similar to those for water conservation.

109. The regulations hereinbefore ordered for the preparation of projects and for the carrying out of works connected with water conservation and supply shall, so far as they are applicable, extend to projects and works connected with navigation.

Power of Trusts to levy navigation rates.

110. Subject to the sanction of Government, and for the maintenance or improvement of any river or other navigable channel, any local Trust constituted under this Act may levy rates from any person using such river or channel for the purpose of navigation.

NOTES AND EXPLANATIONS.

Sections 99 and 100 involve precisely the same principles as have already been provided for in the case of water conservation.

Sections 101, 102, and 104 are intended to meet a well-known objection to irrigation. Most opponents of irrigation, and even some of its advocates, lay down the rule that no irrigation works should be undertaken without provision being at the same time made for drainage. If this system were strictly carried out, there would be few irrigation works attempted. While it may safely be stated that, as a general rule in this Colony, irrigation works will not involve a necessity for systems of drainage, still it is necessary to provide against the possible evil effects of injudicious irrigation. Another important point for which these sections are intended to provide is that the drainage of some of the great swamps which form evaporation pans in which valuable supplies of water are lost should be carried out in such a manner as to render these supplies available for use. It is hoped and expected that works of this nature will, so far as drainage is concerned, be the most important which Local Trusts will undertake.

Section 103 applies to drainage works a rule already laid down in connection with works for water conservation.

Section 105 is one of great importance, and is intended to provide against evils such as have arisen in California through the unregulated use of water for hydraulic sluicing. Under this section Local Trusts will also have the power to regulate the disposal of impure water escaping from manufactories.

Notes and Explanations on PART VII.

India—Act VIII of 1873.

Absence of guiding enactments.

For reference, in the preparation of this portion of the Bill, almost the only available information of a useful description was that contained under the heading of "Canal Navigation" in the "Northern India Canal and Drainage Act." Even this authority could be adopted to only a very limited extent, the circumstances of the country being entirely different to those of India, and the proposed administrative machinery being still more widely different. Hence, in framing this portion of the proposed Bill, it was necessary, in the absence of guiding enactments, to consider the various questions most likely to arise in the management and development of navigation, and to meet the requirements of every case by suitable regulations. While the attainment of this object has been held in view, it follows, from the circumstances of the case, that authorities cannot be quoted in support of the enactments proposed.

Power to detain a vessel till rates are paid.

111. Any Trust possessing jurisdiction over any navigable river or channel shall have power to detain any vessel, boat, raft, or other floating body, till the authorized navigation rate on such vessel, boat, raft, or other floating body, together with the expense of such detention, has been paid.

Sanction required before levying rates.

112. Before rates for navigation can be levied or altered by any Trust the sanction of Government must be obtained.

Trusts not responsible for failure of supply.

113. No Trust shall be held responsible for any damage which may be caused through failure of the supply of water in any river or navigable channel.

Power to raise loans for navigation.

114. Loans for the improvement of navigation may be raised under the same restrictions and subject to the same conditions as are hereinbefore described for works for drainage and water conservation.

Conference of Trusts on matters of common interest.

115. When the whole length of a navigable river or channel is not within the jurisdiction of one Trust, the members of every Trust through whose district such river or channel passes shall have the power to appoint one or more of their number as a deputation to confer with a similar deputation from every other such Trust. At such conference a combined system of management of such river or channel may be arranged, and other matters of common interest to such Trusts may be settled; but all such arrangements and settlements must be ratified at a meeting of every such Trust, and must receive the sanction of the Board before such arrangements or settlements can be acted upon.

PART VIII.—Offences and Penalties.

116. Whoever, without proper authority, and voluntarily does any of the following acts, that is to say:—

Obstructing Government or Trust Officers.

(*a*) Obstructs, in any way, any person in the employment of a local Trust, or of Government, or of the Board, when such person is acting under the authority of the said Trust, or of the Government, or of the Board:

Interfering with marks.

(*b*) Removes, injures, or in any way interferes with any pegs, bench-marks, or other marks, or objects for reference, placed in the execution of his duty by any person employed in pursuance of this Act, in making surveys, levels, or other investigations in connection with any work or project for water conservation or for drainage:

Depositing material on land belonging to Government or to a Trust.

(*c*) Deposits material or refuse of any kind within the bounds of any land resumed or otherwise acquired for any work of water conservation or drainage:

Polluting water.

(*d*) Pollutes, or renders less useful the water standing or flowing in any river or drainage work or work for water conservation:

(*e*) Interferes with the supply or flow of water in any river, creek, stream, or lake managed by a Trust, or causes injury to fences, works, land, or any other property held or managed by a Trust:

Penalty.

shall for every such offence be liable, on conviction before a Magistrate, to a penalty not exceeding twenty pounds, or to imprisonment for a term not exceeding three months; and every such offender shall be liable to a further penalty of ten pounds for every day during which such offence is continued after such person has received notice, in writing, to discontinue the same.

Wilful injury to works.

117. Any person who wilfully damages or obstructs any work for water conservation or for drainage, and any person who, without proper authority, interferes with the supply or flow of water in or from any work constructed or maintained under the provisions of this Act, shall for every such offence be liable, on conviction, to imprisonment for a period not exceeding three years or to a fine not exceeding five hundred pounds, or to fine and imprisonment combined within the limits here ordained.

Waste of water.

118. Any person who being responsible for the proper use and management of a supply of water, subject to the provisions of this Act, neglects to take proper precautions for the prevention of waste of the

NOTES AND EXPLANATIONS.

Notes and Explanations on PART VIII.

Section 116 is framed on the model of Part X of the Northern India Canal and Drainage Act, but departs from it in some important particulars. In the Victorian Water Conservation Act of 1881 the penalty for letting foul water into any stream or reservoir belonging to a Waterworks Trust is limited to five pounds and a further penalty of twenty shillings for every day on which the offence is continued. In the New Zealand Counties Act Amendment Act of 1883 the corresponding penalties, for the same offence, are one hundred pounds and ten pounds per day. The penalty now proposed lies between these, and appears adequate to meet such offences.

India—Act VIII of 1873.
Victoria—Act 716 of 1881.
New Zealand—Act 36 of 1883.

Section 117 deals with a much more serious offence than the foregoing, namely, that of wilful damage to works. In the Victorian Act, above mentioned, this offence is classed as "a felony" and the maximum punishment is imprisonment for ten years. In the New Zealand Act, quoted above, this offence is termed "a misdemeanour" and the offender is declared liable to imprisonment for three years or to a fine of five hundred pounds, in addition to paying the cost of repairing the damage done.

Victoria—Act 716 of 1881.
New Zealand—Act 36 of 1883.

Section 118 is based on the Spanish Law of Waters and the Northern India Canal and Drainage Act. The principle has already been dealt with under Part II.

Spanish Law of Waters.
India—Act VIII of 1873.

water thereof, or interferes with the authorized distribution therefrom, or uses such water in an unauthorized manner, shall for every such offence be liable to a penalty not exceeding ten pounds or to imprisonment for a term not exceeding one month.

119. The penalties directed under last section for the wilful or negligent waste of water shall apply to the water-rights acquired under the "Mining Act of 1874" or under any other Act or regulation in force previous to the passing of this Act.

Compensation to injured parties.

120. Whenever any person is fined under this Act the Magistrate may direct that the whole or any part of such fine may be paid by way of compensation to the person injured by such offence.

Offenders liable to pay compensation as well as penalty.

121. Any person offending against this Act may be sued for compensation on account of the damage incurred or sustained through his offence; and this liability for the loss and damage caused will not in any way mitigate or affect the concurrent liability to punishment for the said offence under the terms of this Act.

Offenders liable to punishment under other Acts.

122. Nothing herein contained shall prevent any person from being prosecuted under any other law for any offence punishable under this Act: Provided that no person shall be punished twice for the same offence.

Careless navigation.

123. Whoever causes any vessel, boat, raft, or other floating body to enter or navigate any river or other channel contrary to the rules and regulations for the time being which have been sanctioned by the Government, and whoever while using a river or other channel for the purposes of navigation neglects to take proper precautions for the safety of such river or channel, or of his vessels, boats, rafts, or other floating bodies, shall for every such offence be liable to a penalty of twenty pounds or to imprisonment for one month, and shall in addition be liable for the value of the damage caused by every such offence.

Section 119 is based on the principle enunciated in Part II, that no one has a right to waste water obtained by him from any public river, lake, or other source, whether natural or artificial. This principle is acted on in India, and also in Italy and Spain; and certainly none of those countries calls so much for stringent regulations regarding the waste of water as this Colony does.

Section 120 is adopted from the Indian Canal Act. India—Act VIII of 187 .

Section 121 is in accordance with the general practice of legislation on such points, and is identical in principle with section 93 of the Victorian Water Conservation Act of 1881. Victoria—Act 716 of 1881.

Section 122 is adopted from the Indian Canal Act. India—Act VIII of 1873.

Section 123 is also based on the Indian Canal Act. India—Act VIII of 1873.

(12.) CONCLUSIONS AND RECOMMENDATIONS.

Legislation and Riparian Rights.

While the Draft Bill already given embodies in detail the principles which, in our opinion, legislation should include, and on which it should be based, the following may be taken as a brief summary of our opinions on this most important branch of the question.

State ownership.

We are of opinion that the most simple, and at the same time perfectly equitable plan to get rid of the mysterious complications of the common law, so far as riparian rights are concerned, is for the Legislature to establish the ownership of the State over all rivers and watercourses, giving to the owner of the land the right to conserve the rain which falls upon it, but not the right to intercept the water of streams or springs which naturally flow through it except by legal sanction. The 30th Article of the Spanish Law of Waters enacts that there belongs to the owner of an estate the rain-water which falls or is collected on it while passing through it. He may in consequence construct within his own property cisterns, tanks, ponds, or reservoirs to preserve it, always providing he does not injure the public or third parties.

Works to be carried out by Local Boards.

Although we attach the greatest importance to ownership by the State of all rivers, water-courses, and lakes, we do not think that, as a general rule, it would be wise that the Government should itself undertake the works which would be necessary to supply the country with water. Having obtained full and indubitable power to carry out all works which may be necessary, and to dispose of the water as may be deemed expedient, we think that the State ought to delegate its powers (with certain limitations) both as to construction and management of works to those whose interests are immediately concerned.

The right to construct overshot dams.

The question of the right to construct overshot dams in creeks and rivers is one which has given rise to litigation, and which is still in a very unsatisfactory state. Owners or occupiers of land adjoining creeks and rivers have, as the law now stands, no right to obstruct the flow of running water, or to erect a dam of any kind. The natural consequence of this state of affairs is that both pastoral and farming interests have been seriously interfered with. The opinion at which we have arrived is, that the privilege of erecting dams, as well as the limits of their heights, and the general nature of their design, can be best decided by local Trusts, composed of persons interested in the creeks or rivers in which such dams are proposed to be constructed. In the draft of the proposed Bill we have, therefore, given ample powers to Trusts to deal with all such questions. In the absence of a local Trust the regulation of the heights of dams, as well as the decision of all other questions relating to water conservation and supply, will rest with the Board which we propose.

Schemes to be controlled by elective bodies.

Inasmuch as the expenditure upon water supply within any particular district must be mainly borne by the land-owners within that district, we are of opinion that the initiation and control of schemes necessary to accomplish the end in view should as far as practicable be vested in bodies to be elected by those who would have to pay the rates and who would reap the benefits. These representative bodies might be the members of local governing Boards, or they might be distinct and separate Water Trusts, such as exist in Victoria, and as described in our Secretary's Report, appended. It is obvious that the residents of a district are better able to judge of their own requirements than any governmental or official authority at a distance, and, so long as care is taken that they shall pay a large proportion of the cost of what they require, they will themselves apply the most effective checks upon neglect, extravagance, and incompetence.

Appointment of Permanent Board.

For the general management of the water supply of the Colony, and the supervision of its administration by Local Trusts, we believe that a permanent Board should be appointed, and that this Board should have power to deal with the construction or management of necessary works in cases which are beyond the capabilities of Local Trusts.

Department under a Minister for Water Supply.

In order that the interests of water conservation and supply may receive in Parliament the attention which they deserve, we are of opinion that a separate Department, under a responsible Minister for Water Supply, should be established.

While

Professional Staff.

While we do not think that it would, except in the case of head or other extensive works, be expedient for the Government to undertake the construction of works for water supply to rural districts, still we are of opinion that it would be absolutely necessary that Government should maintain a small staff of highly skilled engineers, who would be competent to advise them upon the merits of any scheme proposed by the residents of a locality in connection with their application for a loan; and, in the event of the scheme being approved, to periodically inspect and report upon all important works while being carried out under the supervision of the engineer employed by the Local Board or Water Trust, as the case might be. It is important that the Government should have such advice, for several reasons, but principally because without it they would not have the information which would enable them to decide equitably upon conflicting applications, or to ensure that the water available for the supply of a certain area of country was not monopolized by the residents in a particular portion of it; they would not be able to deal satisfactorily with the claims and interests of conterminous Trusts drawing their supply from the same source; they would not have an assurance that, as acting for the whole country in authorizing the allotment of portion of a loan and Parliamentary grant, the works proposed were sufficiently stable and valuable to the general community to justify the expenditure, nor would the particular district more immediately interested have so good a guarantee of the soundness of the scheme propounded by their own engineer as they would have after that scheme had been checked and indorsed by independent and perhaps more highly skilled engineers.

Finance.

We advise that legislation authorizing the making of loans by the Government to Trusts should provide—

(1.) For the taking of a mortgage over the works and revenues of the Trust to whom the loan was granted.

(2.) For the levying by the Trust of a rate sufficient to pay, as a first charge, (*a*) the interest stipulated in the mortgage; (*b*) sinking fund, say at the rate of $1\frac{1}{2}$ per cent. per annum, for the liquidation of the principal sum; and (*c*) for the maintenance of the works in a good state of repair.

(3.) For the Government being required to levy and collect such rate in the event of failure, from any cause, of the Trust to do so.

(4.) For an annual audit of the accounts of the Trusts, so long as they remained in the position of debtors to the State.

Loan for Water Trusts.

The Government of Victoria initiated their system in 1881 by raising a loan of £400,000, which amount has been lent at $4\frac{1}{2}$ per cent. to different Water Trusts upon the security of their works and revenues, in sums proportionate to the character of the works to be constructed, and Parliament appropriated a further sum of £100,000 as a free grant to the Trusts. The allotment of this subsidy is dependent upon the magnitude of the works undertaken by the Trusts, and is intended to act as an incentive to localities to enter upon water schemes. The area of New South Wales being larger, its population sparser, and the extent of unalienated land being greater than it is in Victoria, afford reasons why the amount of the Parliamentary grant should be larger than that of the sister Colony. The loan would be for the construction of specific works to confer a direct pecuniary benefit upon those who undertake them, and not of the continuing, fluctuating, and general character of municipal expenditure; hence a grant in aid seems to be better adapted to meet the requirements of the case than would an annual endowment.

Publicity.

Provision should be made for the utmost publicity being given to all applications for the formation of Water Trusts and for loans to carry out works, and they should be dealt with by the Government only after opportunity had been given to all persons or communities whose interests might be affected to state their objections, in the same way as has always been customary at the inception of new municipalities. In fact, presuming the Water Trust to be a body distinct from the local governing body, all the machinery under which they would act might be almost identical with that established under a Local Government Bill, *e.g.*, the municipal valuation might be used for assessing rates on property.

Head-works.

It may be found that two or more districts would derive their supply from the same source, and that the head-works necessary to provide it would be beyond the means of any, and perhaps of all, to accomplish. In view of this by no means improbable

Union of Trusts.

improbable contingency we suggest that power should be given for the union of one or more Trusts; and it might perhaps even be expedient that the Government should construct the head-works required, where these are of exceptional magnitude and difficulty, and to apportion the rate of contribution by each Trust using the water according to the extent to which it would be benefited.

Urban and Irrigation Trusts.

It would be desirable and necessary that provision should be made for the subdivision of any Trust area, so as to allow an urban population devising and carrying out a scheme of water supply as a separate Trust, or of a community of farmers forming themselves into an irrigation Trust. The requirements of such classes as these are distinct from those of a rural population, and it is obviously just that those who need a special service should pay for the benefits which they exclusively receive, or are capable of receiving. With regard to town supplies, the Engineer-in-Chief for Harbours and Rivers, says (Q. 1117):—"I think it would be a very good thing if the Government were relieved of a great deal of the work now thrown upon them. I think, for instance, that the water supply to country towns ought to be carried out by the local municipalities, and that the Government should be relieved of the duty of carrying them out."

Irrigation.

While the evidence which we have obtained on the subject of irrigation is contradictory, as might be expected from the very limited experience in this Colony of the expense and effects of irrigation, still we have carried our investigations so far as to enable us to arrive at the following important conclusions:—

(1.) That on the alluvial plains extending along the courses of the rivers west of the Dividing Range irrigation of crops can be profitably carried out by pumping.

(2.) That flood-water can under favourable circumstances be profitably used for the irrigation of the natural grasses.

(3.) That the soil throughout the Western plains is, as a rule, eminently suited for raising crops by irrigation.

(4.) That as evidence has been given of large purchases of hay by pastoralists during past years, it is evident that irrigation would increase settlement on the land by making farming on a moderate scale remunerative.

(5.) That by the irrigation of comparatively insignificant areas of lucerne or other crops for hay or ensilage the preservation of stock throughout periods of drought can be ensured.

(6.) That under average circumstances the irrigation of 100 acres of lucerne for every 20,000 acres of pastoral land would afford complete protection against drought.

(7.) That owing to the small available supply, the general dryness of the climate, the absorbent nature of the soil, and the long distances which water will in many cases require to be conveyed, great attention should be given to the economical distribution of the water; and for this purpose we trust that it will be found practicable to make extensive use of pipes, whether of iron or of earthenware, or of some such composition as asbestine.

Agriculture.

Destruction of forests to be under control.

Irrespective of their commercial value, forests render important service in reducing the temperature in their neighbourhood, in moderating hot winds, in increasing the humidity of the atmosphere, in protecting the soil from erosion, and in diminishing the rate of evaporation from the surface of the land or water near them, and we therefore think that the destruction of forests should be under strict and judicious control.

Agricultural irrigation farms.

Agricultural farms established by Government in a locality having command of water for irrigation would probably be very valuable, not only as a means of educating youth in practical and scientific husbandry, but also as affording an example to the agricultural community of the advantages which wet cultivation possesses over every other description of farming. The experience which would soon be

be accumulated with respect to the returns from various kinds of crops under irrigation as compared with ordinary dry tillage would be of very great value.

Drainage Areas.

Coast River Basins.—Although we have taken no evidence regarding the coast districts, the papers placed at our disposal convince us that the question of irrigation in some at least of the coast river basins has up till the present remained in abeyance, simply because the farmers and fruit-growers did not fully understand the benefits which irrigation would confer, and which are so well illustrated in results obtained in the coast districts of Southern California. The best methods for the improvement of the productive capabilities of the coast districts should in our opinion be fully inquired into, and means should be taken, either by lectures in connection with the Board of Technical Education, or otherwise, to make known as widely as possible the importance of irrigation as an aid to production.

Basin of the Snowy River.—The evidence we have obtained tends to show that, in the volume and regularity of its discharge, the Snowy River is one of the most important rivers in the Colony. We are of opinion that it would be a great advantage to this Colony if a portion of the waters of the Snowy River were diverted into the Murrumbidgee, and we have initiated the investigation of the practicability of such a project, but are not yet in a position to come to a decision regarding it. This Colony occupies the same relative position in regard to the upper portion of the Snowy River as the Colony of Victoria holds in regard to the Mitta Mitta, Goulburn, and other tributaries of the Murray.

Basins of the Billabong Creek and Murray and Murrumbidgee.—The compilation of levels made by our instructions have shown clearly that, in the plains between the Murray and the Murrumbidgee, the country slopes from the Murray towards the north-west, and from the Murrumbidgee towards the south-west. This conformation of the country is so favourable for the diversion of supplies from these rivers that the question should in our opinion be dealt with in detail as soon as possible. The discharges of the Murray and the Murrumbidgee should be measured twice every year—once while the snow-water is flowing, and once while the rivers are low. We are of opinion that the creeks and ana-branches should be utilized as far as possible as distributaries, and in our opinion the practicability of such work is so assured as to warrant the commencement of surveys without delay. Being convinced that in addition to the intermittent canals suggested above, permanent canals can be constructed and supplied from the Murray and the Murrumbidgee, we recommend that the surveys required to determine the financial practicability of such canals should be undertaken. The storing of water near the heads of the basins of the Murray and Murrumbidgee, and the diversion of a supply from the Upper Murray, are questions which have come under our attention. We have not yet been able to complete our inquiries regarding them.

Drainage Areas of the Mirool and other Creeks, Basin of the Lachlan and Manara County Drainage Areas.—We recommend that, with a view to conserving and utilizing the flood-water of the Lachlan, that river should be carefully surveyed and levelled. All rocky bars should be noted, and the general character of the bed and banks of the river should be recorded. Surveys should be made and levels taken along the courses of the Booberoy, Willandra, and Merrowie Creeks, on the north side of the Lachlan, and of the Island and other Creeks on the south side. The survey should, in the first instance, include the Lachlan from Cowra to the junction with the Murrumbidgee.

Basin of the Darling and its Tributaries, the Bogan, Macquarie, Castlereagh, Namoi, and Peel.—Water conservation is a work of vital importance for the development of the whole Darling Basin, so that the practical question to decide is in regard to the places where such works are most urgently required. We are of opinion that the Gwydir is the first affluent of the Darling which calls for Government interference. That river should be surveyed and levels should be taken along its course, and thence by the Darling to Walgett. The Great Ana-branch should be included in this survey, the object of which would be to determine the best method of utilizing the flood-waters, and of satisfying the requirements of the riparian proprietors. Next after the Gwydir, the Namoi and the Macquarie require to be similarly surveyed and examined.

Yantara

Yantara County and Tara County Drainage Areas.—In the west and north-west of the Colony, the work being done by the Roads and Bridges Department, in providing supplies of water for travelling stock, is a most important and necessary step towards a system of water conservation. More than is being thus done we think the circumstances of the country would not at present warrant. The necessity for water conservation for the development both of the mineral and pastoral capabilities of the western districts is undisputed. The information at our disposal is, however, insufficient to enable us to form a decided opinion, but we believe that the further development of the underground water-supply is the first step necessary.

SUMMARY OF LEVELS AND SURVEYS NOW CALLING FOR ATTENTION.

Examination of drainage basins.

The Government, by advising the appointment of this Commission of Inquiry, has recognized that the welfare of the community and the further progress of the Colony depend in large measure upon the establishment of a right system for the conservation of water; and by virtue of the State ownership of the land still unalienated it has a direct pecuniary interest in the settlement of the people upon the public estate. Both these considerations lead us to recommend that an examination of the country should be made with as little delay as possible, by engineers competent to advise the Government as to what schemes are practicable (having regard to the population, resources, and requirements of the district), and most advisable for supplying water within the area of each drainage system. They should be instructed to discover if there exist any natural depressions which are capable of being converted into large reservoirs for the storage of water; and, in defining the course of distributing channels throughout any given area, they should, as far as possible, follow the higher levels of the country, so as to give the greatest facilities for irrigation. It should be quite possible for a small staff of engineers, acting in concert with the district surveyors, to indicate within twelve months the most important works necessary to be carried out in the Colony. It is important that the Government should have accurate information as to the nature and extent of the water supply which could be made available; and until this is obtained no useful scheme can be entered upon. The publication of schemes devised by these engineers would show the residents in the particular districts concerned the means by which they could supply themselves with water; and it may be expected that the projects devised by them will form the basis of schemes which the people will themselves seek to carry out.

From the examination of the levels of the Colony and the gauging of the rivers the following recommendations are warranted—

(1.) That as the entire country or doab between the Murray and the Murrumbidgee possesses remarkable facilities for irrigation, both from permanent and from inundation canals, a complete series of cross-sections should be made from river to river, and an estimate prepared for distributing the whole available supply of water on a comprehensive system.

(2.) That the practicability of storing water on the Upper Murrumbidgee and of conducting a supply from the Snowy River to the Murrumbidgee, should be determined by surveys and levels.

(3.) That the practicability of diverting water from the Tooma River or the Upper Murray into the Billabong, and also of storing supplies in the Upper Murray, should also be determined.

(4.) That the adaptability of Lake George and the principal lakes of the Colony as storage reservoirs for flood-water should be investigated.

(5.) That such cross-sections of the country or doab between the Macquarie and the Bogan should be made as will show the lines along which flood-water from the Macquarie can be most usefully diverted, and that traverse surveys and longitudinal sections of the Macquarie and Gwydir Rivers should be made.

(6.) That where the Harbours and Rivers Department has not already done so, longitudinal sections of the Murray, Murrumbidgee, Lachlan, and Darling, beginning from Tintaldra, Gundagai, Cowra, and Walgett, respectively, should be made, and that when taking such sections, particulars as to heads of creeks and ana-branches should be noted.

The

The existence and direction of subterranean supplies and currents can only be determined scientifically, and to full advantage for the benefit of the country, by a compilation of special hydrological and geological maps, which we recommend should be commenced without delay.

Expression of thanks.

We desire to express our grateful sense of the promptitude and courtesy with which our applications for information have been replied to by the Secretary of State for the Colonies, the Governments of various European States, the Government of India, the Governors of the States of California and Colorado, the Royal Commission on Water Supply for Victoria, the Departments of Water Supply of Melbourne and Adelaide, the Campbelltown Water Trust, Tasmania, the Government of Queensland, and the Heads of Public Departments in Sydney.

Appendices.

We attach hereto Appendices, as follows :—

Report on canals and irrigation in India, by Mr. F. A. Franklin, C.E.
Report on river-gauges, showing list of present and proposed sites, by Mr. H. G. M'Kinney, M.E., M.I.C.E., the Engineer to the Commission.
Report on railway and other levels in the interior of the Colony, by the Engineer to the Commission.
Further report on levels, by the Engineer to the Commission.
Report on the Tantangara Basin, Upper Murrumbidgee, by Mr. Cornelius Haylock, L.S.
Report on Mr. C. Haylock's survey of the Tantangara Basin, by the Engineer to the Commission.
Report on the River Murrumbidgee as a source for canals, by the Engineer to the Commission.
Report on the River Murray as a source of supply for canals, by the Engineer to the Commission.
Report on the Namoi River, *with plan*, by Mr. F. B. Gipps, C.E.
Report on conservation of water in Victoria, by the Secretary.
Report on the Barwon River, and Tarrion and Cato Creeks, by the Engineer to the Commission.
Report on the Macquarie River and the district between the Macquarie and Bogan Rivers, by the Engineer to the Commission.

APPENDIX.

REPORT ON CANALS AND IRRIGATION IN INDIA.

To The Colonial Secretary.

Sir, Sydney, 30 July, 1884.

I have the honor to furnish you with a report on the Ganges, Jumna, and Sone system of canals and irrigation in India.

In accordance with your instructions, conveyed to me by telegram on the 8th February last to examine into the system of water conservancy of Bengal and Upper India, I took the earliest opportunity, on the completion of my work in connection with the Calcutta Exhibition, to proceed first to Arrah, the central district of the Sone circle of canals. At that place arrangements had been made by Colonel J. M. Heywood, R.E., Superintending Engineer, to proceed with me to Dehree, the head works of the system. The whole of the works were minutely described, and the practical working of shutters, sluices, and regulators illustrated by G. Shawe, Esq., C.E., Executive Engineer of the district. Upon completion of the inspection of the highly interesting system of the district, the next work visited was the terminal point of the Ganges Canal at Cawnpore. From thence I proceeded to Agra, and examined the escape of the Delhi Canal at that place. I afterwards went on to Delhi to make myself acquainted with the head works on the river Jumna, at Okla, 10 miles below that city.

On completing my inquiries at Delhi I went on to Roorkee, and thence to Hurdwar, the head works of the Ganges Canal, 20 miles above the town of Roorkee. Being provided at this place with an elephant, and accompanied by the resident engineer, I was enabled to inspect the mode of training the Ganges towards the off-take of the canal. When returning to Calcutta I branched off by the Oudh and Rohilcund Railway to Rajghat, and visited the head works of the Lower Ganges system.

The Upper Ganges Canal.

This project was first conceived by Colonel Colvin, R.E., in 1836, but nothing of a practical nature was done until the great famine of 1837–38 forced the question on the serious attention of the Government. Colonel Cautley having succeeded Colonel Colvin, who was very sanguine of the success of the scheme, strongly urged his successor to continue the examination. In 1848 the work was commenced with great vigour.

The head works of this great canal are situated at the sacred town of Hurdwar, within sight of the snow-capped peaks of the Himalayas. The source of the great river is at Gungotri. A little above Hurdwar the Ganges throws off a branch about 250 feet broad, which is used as the supply channel for the canal. The quantity of water taken off is regulated by sluices, and the remainder is allowed to rejoin the main river lower down. The bed of this branch has been deepened to an uniform slope of 8½ feet per mile, and the erosion of the banks is prevented by spurs or bunds placed transversely with the axis of the stream. The general bed of the Ganges above this point is but ill defined, and the current liable to constant change. Therefore, in order to obtain a regular supply, the head of one of the main channels is closed by a temporary dam, composed of timber cribs filled with boulders, and built up to flood level, which can be removed when threatened by more than ordinary flood. The other channels are closed by temporary bunds of moderate height, so that the supply channel to the canal is under complete control. Just above the entrance to the canal a permanent bar has been constructed as an escape (communicating with the main river), and to regulate the cold weather level.

The entrance to the canal is at Myapoor, and then commences a complete series of works of a most extensive character. They consist of a masonry dam some 600 feet in length (in course of reconstruction at the time of my visit) across the Pyree branch. This dam is provided with sluices, and across the entrance to the canal is a masonry bridge of ten arches, each 20 feet wide, fitted with shutters or gates for regulating the admission of the water as may be required for navigation or cultivation.

Between the Myapoor headworks and the high land on which Roorkee is situated, the canal traverses a line which bisects several mountain streams. On this portion of country the most formidable obstacles to the project were met with. The tract of country referred to is triangular in shape, the northern side being formed by the Sewalik hills, the eastern by the river Ganges, and the western by the high land which constitutes the boundary of the valley of the Ganges. Along the direction of a rapid slope the line of canal is carried, and the drainage of three mountain streams which cross the canal at right angles is provided for by works which will be hereafter described.

The canal is 140 feet wide at the bottom, has a slope of 1½ to 1, and the water is 10 feet deep. It is constructed with a fall of 15 inches in every mile, but this is much less than the natural fall of the country; the excess of slope is therefore provided for by artificial works. To this end masonry falls are formed between Hurdwar and Roorkee. To regulate the slope of the channel from Hurdwar to Roorkee there are four such falls of 9 feet each. The navigable canals which form loops round these falls are furnished with locks, compensating the fall in the main canal. The total fall of 36 feet delivers the water at Mahewar, 27½ feet above the level of the Solani River valley, within a mile of Roorkee. The first mountain-stream or rao is the Puttree, conveyed over the canal by superpassage, which merely acts as a watercourse during floods, and at other times may be used for the purposes of cross-communication. The work is of a very massive character, with strong parapet walls. The catchment area of this torrent is about 80 square miles, having a width of 5 miles, and an average length of 16 miles, commencing at the Sewalik range of hills and terminating at the superpassage. The superpassage consists of eight arches, of 25 feet span each, which discharge the canal supply. The fall of 9 feet takes place above each arch, and the ninth arch provides for navigation, the lock-gate being attached to the bridge. The water-way over the superpassage is 300 feet in the clear, the parapets being 14 feet high. The Ranipore superpassage is in most respects similar to the above, except that its water-way is only 200 feet wide in the clear.

The

The next work of magnitude is at Dhunowree, at the intersection of the Rutmoo Rao or River, which it meets and crosses on the level of the canal-bed. The works designed for the passage of this river across the canal consists of a masonry apron on the right and a regular escape dam on the left bank, provided with forty-seven sluice-gates 10 feet wide, with sills flush with canal, and connected by revetment walls, with a traffic-bridge on the up-stream side of the canal, and a regulating bridge on the down side. In addition to the sluices just referred to, there are on each flank five other sluices, with sills raised 6 feet, and on the extreme flanks are platforms or weirs at the permanent or maximum level of the canal, so that in extreme floods an escape across the canal is provided for a width of 800 feet. The whole of the escape sluices can be opened very quickly by a very simple contrivance, the chains holding the gates being released by a slight tap with a hammer.

The regulating bridge is composed of ten arched spans of 20 feet each in the clear, with necessary apparatus for raising and lowering. By these means an immoderate storm discharge is completely under control. On the occurrence of a flood the dam sluices are opened and the regulating gates of the canal bridge closed, so that the excess water is conveyed away harmlessly to the natural bed of the river, the middle sluice gates allowing the escape of silts to the level of canal bed. On the termination of a flood the canal regulator is again opened, and the dam sluices are closed, thus allowing the canal supply to run at its ordinary level. This is a most important work, and upon its accurate supervision depends the safety of the works lower down.

The next work is the deservedly famous Solani aqueduct. This great work is situated at the 19th mile from the head, at the point where the canal leaves the high land of the Ganges. The Rutmoo and Solani rivers are separated by a high ridge of land about 2 miles in breadth, through which the canal passes in a deep excavation. This runs out at the Solani Valley, which is 11,680 feet wide, or nearly 2¼ miles. The canal is now carried above the surface of the valley by an aqueduct 15,700 feet long. The masonry aqueduct itself, which crosses the river bed, is 920 feet long, and consists of fifteen arches each of 50 feet span (giving a clear water-way of 750 feet), with 9 feet piers. The width of foundations in piers is 252 feet, and the extreme width of water-way on top is 172 feet, by a maximum depth of 10 feet. It is divided in the centre by a wall throughout its length, and grooved to receive planks, in order that one half of the aqueduct may be closed if necessary. The canal level at this point is 24 feet above the Solani river-bed, and the whole work is of stupendous dimensions. The banks of the canal on the up-stream side of the aqueduct are revetted by masonry steps for a distance of 10,713 feet, and for 2,723 feet on the down stream, or Roorkee side; that is, a total of 13,436 feet. The embankment supporting this channel has a base of 350 feet, and a top width of 290 feet, which provides for a road on either side. At the time of my visit the velocity of water was 3½ miles per hour, and the depth on gauge 8 feet, or 2 feet below the maximum. The total height of the aqueduct above the river is 38 feet. The deficiency of elevation robs it of much of its grandeur when viewed from below, but above when its extreme width and length of masonry channel are viewed, the effect is most striking.

The foregoing is a brief sketch of the works on the first section, from the training works to Roorkee. It would be impossible to give anything like an estimate of the amount of labour expended on them.

The canal, after passing the high land of Roorkee, flows east of Mozuffurnuggur and west of Meerut, following the high land to near Bolundshuhur, where a short branch occurs, and continues to a short distance below Allyghur, where it terminates or, rather, diverges into the Cawnpore and Etawah branches.

The former flows on the high land between the rivers Esun and Rind, and discharges into the Ganges at Cawnpore, a distance of 170 miles, and navigable throughout. The latter continues through the high land, and after a course of 170 miles flows into the Jumna, near Humeerpore.

Throughout the length of the main canal and branches the longitudinal section is laid out in a series of steps, the length of tread and height of rise being determined by the profile of the country. These weirs or overfalls were originally designed in the form of an ogee, but it is now agreed that the vertical shape is the best. There are fourteen of these falls in a distance of 165 miles from the head, aggregating 110 feet. The falls consist of bridges, as already described, with varying numbers of arches, according to the waterway required. At 68 miles the canal is diminished in width to 150 feet, and at 149 miles to 100 feet to compensate for the quantity of water taken off for irrigating purposes.

The navigation in the canal is of minor importance, but in order to maintain it small channels 20 feet wide are constructed three-quarters of a mile above each fall, and re-entering the canal at about the same distance below.

On these channels locks are provided at the point corresponding with the weir or fall in the main channel. At most of these locks corn or sugar mills have been erected, worked by water power.

In consequence of local irrigation, and frequently to an irregular abstraction of water from the main channel, the equilibrium between the supply and the capacity of the channel is liable to be disturbed. At its source the climate is moist, but on entering the plain country the climate is entirely changed, and demands are made on the supply which varies with regard to climate and soil, and is greatly influenced by local rainfalls. These conditions are met by providing escape outlets at intervals along the line of the canal, so that when overcharged the surplus water may be passed off into side channels. These escapes on the Ganges Canal are situated about 40 miles apart. They consist of a number of sluices about 6 feet in width, are built in the side road, and are arched over so that a free passage is open to both traffic and water.

At the end of the main canals, where it divides into the Cawnpore and Etawah branches, are two regulating bridges, one over each branch, connected by a masonry wall. These bridges have each five openings of 20 feet, fitted with gates and apparatus to admit of proper subdivision of supply; and in cases of necessity one or other of the branches can be laid dry.

On both banks, along the whole line, plantations of useful shade trees have been formed. The distances are marked by substantial mile-posts, and at nearly every bridge are provided bathing ghats for the natives.

The Cawnpore terminal line passes the station near the Cantonment. At this point it has wide and handsome esplanades, with trees, ghats, and bridges, which are quite an ornament to the locality.

The junction with the Ganges is effected by a series of locks for the passage of boats to or from the Ganges or Cana.

The total length of main and branch navigable canals in this system is 890 miles, and 3,700 miles of distributing lines, along which are established 17 dams or escapes, 202 bridges for the purpose of traffic or regulation of supply, with waterways varying from 200 feet to 20 feet, 297 inlets for local drainage, 16 falls, and 31 locks and side navigable channels, and 282 outlet heads for irrigation. The

The preceding details will suffice to give an impression of the extent and dimensions of the Ganges Canal. Up to the end of 1877-78 the expenditure on the canal had been three millions and fifty-five thousand pounds (£3,055,000). The area irrigable is 1,205,000 acres.

The Lower Ganges Canal.

This is comparatively new work designed to compensate for the admitted fault of placing the head of the upper system so high up the river as Hurdwar. The work was recommended by Sir Arthur Cotton in 1863, and after some alteration in the design first proposed the work was commenced by the construction of the masonry weir across the Ganges, at Narora, in 1871. This weir is situated about 3 miles below the crossing of the Oudh and Rohilcund Railway at Rajghat, 30 miles from Allyghur, on the East Indian Railway. From this point the main canal traverses the Allyghur, Etah, and Mynpoorie districts, crossing the Cawnpore branch of the Upper Ganges Canal, 76 miles from the terminus, thence running westward of the town of Cawnpore to the district of Futtehpoor. The length of canal channel is 531 miles, of escapes 56 miles, of navigable channels 428 miles, distributaries for irrigation 1,834 miles.

The works at Narora consist of a masonry weir across the Ganges, having sluice openings only on the flank where the canal takes off. At the time of my visit I was unable to obtain the assistance of the resident engineer; the measurements given with the following description are therefore only approximate.

The weir sluices are divided in bays of 14 feet and 8 feet waterways; the shutters are of iron, with very improved apparatus for lifting. The weir is connected with the canal take-off by a wing wall, 130 feet in length, and the bank on the lower side is protected in a similar manner for the same distance. At the end of weir openings a ramped-wing wall, 7 feet wide, extends down stream 130 feet as a protection to slope of dam. The main dam or weir is constructed on a loose sand-bed, and the long down-stream slope is packed with large pieces of kunker in the absence of stone. The crest of the weir is 10 feet above the river-bed, but this height can be further increased by the use of iron shutters hinged to crest of weir. On the up-stream side of the weir the low nature of the country necessitates the maintenance of a bund for a distance of 5 miles, to prevent the spread of flood-water.

The water is taken off to the canal by thirty sluice gates, the width of inlet being 300 feet. The shutters or doors are fitted to the full depth of the river at entrance, and any silt that may collect at the entrance is removed by the scour from the sluices in the weir already described above. At a distance of 750 feet above the weir is the lock-entrance, with gates of the ordinary kind, the river bank for the whole length from weir to lock-entrance being protected by a masonry revetment, which also extends beyond and protects the upper wing of the lock.

The design and construction of this work embrace every improvement that long experience and modern science could suggest, and may be looked upon as a reliable type to follow in any works of a similar character projected in this Colony.

It is to be regretted that time and an unfavourable season did not permit of a thorough examination of this system, as the head works offer sufficient promise that all the details throughout would prove of a highly interesting and instructive character.

The Agra Canal.

This canal was completed in March, 1874, and the distribution of water commenced in the following cold weather. It commands an area of 375,800 acres. The head works of the canal are situated at Okla, 10 miles below Delei, on the River Jumna. The weir is 2,400 feet in length, and the crest is 7 feet above summer level of the river. The maximum height of flood at the weir is 11 feet, with a velocity of 5¼ miles per hour. The rear slope is composed of large size, hand-packed rubble, laid to an incline of 20 to 1. The through walls of the weir are laid directly on the river-bed, without block or well foundation. This was the first attempt at construction of this nature on a bed of the finest sand, and the work appears to stand well. At the end of the weir, where the canal takes off, there are sixteen sluice openings of 6 feet 6 inches each, flanked at the land side with a revetment extending down stream for protection of the bank, and up stream 60 feet, where commence the under sluice openings for canal supply. The width of canal is 100 feet, and the water entrance is arched over to form a traffic road. The masonry wall continues for 150 feet, and is then curved to entrance of lock communicating with canal. The whole of the work is executed in rubble, with brick strings and copings, and is of a very substantial character. The sluice-shutters are dropped in a cast-iron channel plate, and are lifted by a traveller provided with winch and gear, running on a line of rails attached to the piers. The depth of water at entrance is 8 feet, and the canal entrance is formed in excavation 20 feet in depth.

The main weir on the up-stream side is well protected with rubble stone, and, excepting at the entrance to sluice openings, is silted to level of dam crest. Shutters are now being fixed to the weir which will raise the level of the water impounded 3 feet 6 inches.

An embankment along the river margin for about 8 miles protects the low lands from inundation, and the chance of turning the flank wall.

From Okla the canal follows the high land, nearly parallel with the Jumna, at a distance of from 3 to 12 miles from the bank of the river, and finally discharges into the Utongou River, 20 miles below Agra. Branches connect the canal wish Muttra and Agra. Both of these are navigable, and when a full supply of water is obtainable boats can pass into the Jumna again at Agra. At the time of my visit the outlet was temporarily closed.

The discharge of the Jumna at Delhi in the dry seasons of the year is about 700 cubic feet per second, although the Upper System draws off the entire discharge of the Jumna, as it passes out of the Sewaliks.

The length of the main canal for navigation and irrigation is 140 miles, and the short junction to Agra and Muttra and length of distributaries 288 miles. The entire work cost £932,907, and the returns realized 10 per cent. on outlay.

New extension works are now in progress to make a navigable junction with the Western Jumna System at Delhi; and at its junction with the main canal near the head the excavations are heavy for some distance.

The foregoing is a brief sketch of the canals in the north-west provinces and Oudh, which I was enabled to examine during my visit; and for the assistance rendered in my inquiries by the officers in charge of the several works I am indebted to the courtesy of Lieut.-Col. J. G. Forbes, R.E., Engineer-in-Chief of the district.

The

The following is an extract from a report on the highly prosperous condition of the irrigation works of the North-west Provinces, dated 22nd February in the present year:—"The gross assessments for 1882-3 amounted to £645,000, and the working expenses to £215,000. The net revenue is therefore set down at £430,000, which is equal to 6·36 per cent. on the capital invested. The length of main canals is now 1,384 miles, of the distributaries 5,596 miles, and of the drainage cuts 1,403 miles. The total irrigated area is no less than 1,974,175 acres, or 3,085 square miles."

The Sone Circle System—Bengal.

The country benefited by this system of canals lies southward of the river Ganges, near the junction of that river with the Sone. It comprises portions of the district of Shahabad, with Gija and Patna on the east. The first idea was to irrigate the Shahabad district from storage reservoirs in the hills; but subsequently the supply of water in the Sone River was found sufficient to irrigate an area of 800,000 acres. It was therefore finally determined to construct the works now existing, of which the following is a description, at a cost of £3,775,000, and to command an area, when complete, of 2,611,000 acres.

The estimate provided for irrigating 1,305,000 acres of rice land, and the allowance of water for this crop was fixed at 1 cubic foot per second for 133 acres; hence the eastern main canal was designed to carry 4,511 cubic feet per second, but, as will be shown further on, the expectation was not realized.

The excellent works on this system were commenced in 1869. The weir across the Sone, which is the headwork of this system, is situated at Dehree, about 27 miles below where the river leaves the Kymore range of hills. It is the longest weir in one length which has ever been built. It is 2¾ miles in length, and 8 feet high to surface of crest. The cill level is 326·00, and highest flood level 342·00. The flood therefore rises 8 feet over the crest of the weir, and discharges about 1,026,000 cubic feet per second. Its average minimum supply in the cold season is 3,000 feet per second, but at times in exceptionally dry seasons it has been known to fall below this quantity. The catchment area of the Sone is 23,000 square miles. The river runs for 225 miles through the hilly parts of Central India, until it reaches the plains of Rhotas. From that place it has a course of about 100 miles through an almost deltaic country, which is the area commanded by the Sone canals. For some 40 miles below the weir the floods do not overflow the banks, but below that point large areas are inundated. Up to the point where flooding occurs the canals on each side follow the line of river closely, and then follow the high ridge of the country down to the Ganges.

The following are the lengths of the navigable canals:—

Main Western	21½	miles.
Arrah branch	65	„
Buxar branch	45	„
Main Eastern	7	„
Patna branch	79	„
	217½	miles.

The length of branch canals is 107 miles.

In addition to the above there are 1,130 miles of distributaries connected with the mains. The full summer supply carried by the canals is ascertained to be 5,171 cubic feet per second, and the minimum at end of dry season 3,500 cubic feet; but it has been known to fall 500 cubic feet in a very dry year, about May and June. The total irrigable area is 1,100,000 acres, and the total area commanded by the canals is estimated to be 2,931 square miles, making the area irrigable about 70 per cent. of that commanded.

The headworks are situated 58 miles from Arrah, and the journey is performed by steamer. On this branch there are thirteen locks, two of which are double. Some two hours are occupied in passing the locks, which have an average rise of 12 feet each. The total fall from the bed of the Sone at Dehree to low water in the Ganges is 180½ feet, of which 161 feet are overcome by means of the locks, the difference being accounted for by the slope of the canal. The steamer used was a side wheel, with breadth over sponsons of 19 feet, for the clearance of locks, which are 20 feet wide in the clear. The passenger and goods traffic is considerable, and is said to pay.

At intervals of 2 miles pontoon bridges, or stages, are moored to either bank for the convenience of ryots who may wish to cross over themselves, or convey produce from bank to bank. And in addition there are frequent over-bridges for general traffic.

At the side of each lock, in a loop branch of the main canal, is a masonry weir, with a fall corresponding with that in the locks. The openings for discharge are regulated by boards fitted into slots worked in the masonry. At a short distance from, and on the upper side of, the locks are sluice openings for supplying the side channels, which in this system run on either side of, and parallel to, the main canal, and from which the distributaries are supplied, instead of from the main channel. The connection with the distributaries are made by village channels formed by the natives in any direction required, under the supervision of the local officers.

The Anicut, or main weir, is 12,351 feet long between the abutments. It is constructed of rubble masonry, having foundations of rectangular wells sunk in the river bed, supporting longitudinal walls 5 feet and 4 feet respectively placed 35 feet apart, the intervening space being filled with large ordinary packed rubble. The front or up stream slope is formed at 3 to 1, and the rear or down stream slope at 1 in 12, formed also of large size, hand-packed rubble. The packing on the crest is closely cemented.

There are three sets of under sluices in the weir, one at each flank and in the centre, each with twenty-two vents or openings of 20½ feet each. The piers between the openings are 4 feet thick, and 32 feet in length. These sluice piers are set in ashlar masonry to a height of 10 feet over river-bed. The shutters or gates used for closing the sluices are extremely novel in construction, being in a great measure self-acting. The shutters are arranged in two lines each at the end of the piers, fixed by hinges to sill of opening. The back of the up-stream shutter is supported by six tension rods, 2¾ inches in diameter in wrought-iron tubes, the rods being packed with leather to act as pistons. When the shutters are up the packing fits close to the inner surface of the tube. If it is desired to lift the shutters during a rise in the river they are raised by means of appliances 8 inches, when the pressure of the water does the rest, the shock of the sudden pressure being modified and injury prevented by the tube and piston arrangement.

arrangement. The front shutters being up, the back ones are easily raised. The space between them is then filled with water through a valve in the front shutter. When the water is in equilibrio the front shutter is again lowered to its bed, and one only is left to retain the water. The remaining shutter is attached to the floor by strong iron rods hinged to gate and floor, and fixed below the centre of oscillation, so that when the water rises beyond the height required to serve the canal the shutters fall and the river discharges itself throughout the whole length from bank to bank.

It was proved in my presence that by this admirable arrangement these shutters can be safely and expeditiously lifted against a 10-feet head of water without shock to the structure. It is an interesting and instructive sight to watch a stream of water 20 feet broad and 9 feet deep flowing with a velocity of about 18 feet per second through the sluices suddenly obstructed by a single gate. When the shutter reaches the vertical the water leaps in a wave 2 feet above the top and flows over for a few seconds, and then sinks to the mean level of the upper pool.

The set of gates in the centre being over a mile from the shore, it was on one occasion found impossible to reach it in time to disengage the chains, and to drop the shutters on the approach of a sudden flood. A great deal of damage was done in consequence to that portion of the work. Since then automatic means have been devised to meet the difficulty in future.

As in the case of all other headworks described, the revetment walls are continued some distance up and down river at right angles with the weir, the take-off for the canals being on each bank near the up-stream side of the weir. The western and eastern head sluices discharge 4,342 cubic feet per second. They consist of twenty-four vents of 6 feet each, fitted with gates in two panels, one or both in each opening being removed at will. Above them again on each side of the river is situated the navigable lock entrance.

The dimensions of the western main is, at the head, 180 feet in breadth of base, with slope 2 to 1, giving a surface waterway of 220 feet with a maximum depth of 9 feet, the fall being 6 inches per mile. Five miles from the head the canal branches to Arrah and Buxar. On the latter branch, at its junction, a regulator was being built at the time of my visit to compensate for increased slope and consequent excessive discharge. From this point the width of each canal is reduced to 124 feet, the Buxar branch taking off 2,895 cubic feet of water, and the Arrah 1,447 cubic feet per second. At the 12-mile the Chousa branch occurs, 1,226 cubic feet being taken off, leaving 1,669 cubic feet to be carried on. From this point the canal narrows to 100 feet, and the fall to 2½ inches per mile. At the 19th and 21st mile respectively the Khurgur and Chowbay branches take off, depriving the main canal of 620 cubic feet of water, leaving 1,049 cubic feet to be carried on to the end of the canal at the 22nd mile.

The Arrah branch has already been described, as seen on the trip up from Arrah; and the same description will apply to the branch on the eastern side of the river, the details in all cases being similar. All drainage streams are crossed by masonry aqueducts; the distributaries are supplied by side sluices arched over to carry roads; the banks are closely planted with trees, and light iron bridges with timber floors span the canals at frequent intervals. At some of the locks sugar and floor mills are worked by water-power applied by turbine, and are productive works. The same power, placed at the disposal of the enterprising settlers in this Colony, would be availed of to its fullest capacity. In India the Government provide the whole of the working appliances.

In concluding this brief description I must express great indebtedness to H. C. Levinge, Esq., C.E., late chief engineer of the works, for much valuable information, and to Lieut.-Col. J. M. Heywood, R.E., the present chief engineer, who provided means of transit, and placed at my disposal the valuable plans of his Department, and accompanied me for several days on a tour of inspection over the works. It is through the instrumentality of this gentleman that the Government of New South Wales has been furnished with complete sets of drawings and books of reference of the whole of the irrigation works of Bengal.

The distance travelled by rail, canal, and road, for the purpose of inspecting the foregoing works, was 2,740 miles, and the character of the climate of the country passed through was as various as the systems adopted by the natives in economising and distributing water for irrigation. It may, therefore, be interesting to describe the various methods of raising water in vogue among the natives of India.

Well Irrigation.—The two methods which are to be frequently met with between Calcutta and the north-west provinces are the pecotah, in Bengal, and the môt in the north-west provinces.

The pecotah is a lever fixed to an upright forked post, with a bucket attached to the short end by a rope, and a counterpoise at the other end. It is worked by two men, and it is stated that in six hours they can raise and distribute 1,500 cubic feet of water from a depth of 20 feet. When the depth is not more than 16 feet one man works the pecotah with the following results:—With a bucket containing 3 gallons and discharging 3 per minute, or 540 gallons per hour, or, deducting spillage, 4,000 gallons per day, which is sufficient to water two-thirds of an acre.

The môt consists of a leathern bag, having a leather pipe-like extension at the bottom. When the bag is filled it is raised by means of a rope, running over a pulley, worked by two bullocks walking down an inclined plane, either excavated or made over the surface to the level of the raised masonry of the well. At the side of the well is a trough into which the water is discharged. Three men and two bullocks work this appliance from morning till evening, with a mid-day rest of an hour. The bag contains 4·5 cubic feet, and can be raised thirty times in the hour, which gives a result of 6,720 gallons per day of eight hours.

Both of the above systems, notwithstanding the cheapness of labour, are considered very expensive compared with surface irrigation, and they are therefore of only very restricted application.

The wells generally are not very deep, reaching from 18 to 20 feet, but the supply in most parts is very scanty, and a very small depth of water remains while the môt is in use. The ordinary field well is simply a round hole, lined for a few feet of its height from the bottom with a plaited brush-wood casing.

The country in India, through which the great systems of canals are carried, resembles very much in appearance our western and north-western country. The main channels in every case are formed on the ridges to be found on each side of the main rivers. These ridges, which exist in varying widths, right and left of the river channels, have been formed by the gradual deposit of alluvial matter when the rivers have been in a state of flood, and they occur at points where the velocity of the stream is checked. The effect is to leave on each bank a stratum of silt, in the sectional form of a long wedge, with the thick end towards the river. The width of this slope on the plains of India varies from 300 yards to a distance of

many

many miles. Beyond these deposits, which occur also on all tributaries of such rivers, the country is low, and although not perceptible to the eye, yet instrumental examination shows in which direction the drainage tends to flow. The irrigation of India is therefore based on a very simple principle.

At all the sites selected as the head works of the several systems which I visited the river appears to have ceased to overflow the banks at time of floods. By raising the level of the water at these points by means of a fixed weir, and excavating a channel through the wedge deposit, the lower country is reached, and as the line of canal is carried in a straight direction, while the course of the river is tortuous, the fall is more rapid; for every mile of its course it then gains considerably on the surface level of the river. As an example, if the fall of the Darling or Murrumbidgee is 1 foot per mile, with a tortuous course of one half more than a direct line, there will be a gain of 6 inches fall in each mile in an artificial channel. So that if the excavation of the canal were 5 feet below the top of the river bank at the head it would gain that amount on the river in 10 miles. If the cut were made in ground on the same level as the margin of the river bank, the water it carried would then come to the surface, and be available for distribution.

But as the wedge-shaped alluvial deposit carries a fall at right angles to the axis of the stream as well as in its course, the required level would be obtained at a shorter distance, and as the fall in the cut need only be 6 inches in the mile the water would come to the surface in 5 miles. The foregoing is practically the system adopted in India. The excavations are made so as to be little more than sufficient to provide material for the embankments, which are made to retain the water at as high a level as possible consistent with their stability. And then occur the lock and weir as described in the Ganges and Sone systems.

In many parts of India large tanks or reservoirs are established in the upper watershed to collect and distribute by means of sluice regulators, the water which would otherwise inundate the lower land. These tanks are provided with escapes or waste weirs which convey the surplus supply to the natural bed of the drainage. The plan adopted is to select a natural hollow in good holding ground on the moderate slopes of the catchment area, by closing up all depressions on its sides where water can make its exit, and excavating in the solid, throwing the material into a dam or bund at the lower end. The supply for these tanks sometimes depends entirely on local rain, or on streams swollen by rain on the higher ground above; or, as is more generally the case, the tanks are filled by tanks connecting several of these streams, or by channels widening round more remote hills.

When practicable, the head of supply is cut off when the tank is filled, and the surplus water discharged into the natural channels; otherwise one or other of the following methods is adopted. When the banks at the site of the dam are high, as in the bed of a mountain stream, and of a great width, the dam is constructed entirely of solid masonry throughout, so that the waste water may pass over the whole length of the dam. If so large an escape is not desired and the embankment be of earthwork, then a portion of the dam is built in masonry, with the top 2 or 3 feet lower than the earthwork; but where the position is favourable several waste weirs excavated in the solid ground are much more reliable. In Mysore there are upwards of 20,000 tanks, the dams of which are of lengths from ¼ of a mile to 1½ mile. They are principally formed of earthwork, 12 feet broad at top, 60 feet on bottom, and 18 feet high. They are faced with a rough stone revetment, having a batter of 2 to 1, the facing averaging 3 feet to 4 feet 6 inches in thickness, packed on loose rubble backing.

The largest tank in India is the great Chembrambaukum, 9 square miles in area; it is situated 14 miles from Madras; its capacity is 102·91 millions of cubic yards, and the water spread is 5,729 acres, or 8·95 square miles. The Government is now considering the question of forming large storing tanks at the head of the watersheds under the mountains. In the Bombay Presidency five examples of tanks are found. The Ekruk tank is one of the largest of its class; it comprises a reservoir or tank formed by an earthen dam, and three canals for irrigation. The dam is 7,000 feet in length, and 76 feet in maximum height; it is thrown across the Adhila River, a tributary of the Lind. The drainage area above the tank is 160 square miles. The tank is 60 feet deep when full, and contains 3,350,000,000 cubic feet. The area of the water surface is 4,640 acres, or 7¼ square miles.

The Bhatode tank is situated on the Mekhri River, which rises 10 miles north-east of Ahmednagar. The masonry dam is 2,400 feet long, and 50 feet in maximum height, with a waste weir, 450 feet long, 7½ feet below the top of dam. A canal for irrigation is 4½ miles long, and is capable of discharging 140 cubic feet per second at the head, and commanding altogether 14,000 acres of land. The drainage area of the tank is 50 square miles, its capacity 149,000,000 cubic feet, and its area, when full, 310 acres. It is estimated to fill with a rainfall of 5·40 inches.

The Naini tank is situated on a small tributary of the Yula River. The work comprises a storage reservoir, capable of containing 190,000,000 cubic feet, and having an area, when full, of 380 acres. It is formed by an earthen dam 2,870 feet long, and 57 feet in greatest height. The catchment area of the river above the dam is 54 square miles. The canal leading from the tank has a discharge capacity at the head of 33 cubic feet per second.

There are in the Presidency seven smaller works of the same description, some of them undertaken entirely by the Government, and others being old native works restored.

In the Western Punjab, where rain is very scarce, and the ground near the hills at so high a level that it is impossible to irrigate it either from canals or wells, the natives obstruct the dry bed of the stream with dams formed of earth and brushwood at every favourable point, thus raising the level of the water, and directing it into secondary channels, natural or artificial, whose mouths are just above the dam. Each of these in its turn is bunded as may be required to throw the water in the smaller irrigating channels for distribution over the land. So skilful is this arrangement that although these floods last but a few hours the water is distributed in the above manner by hundreds of weirs and minor channels over a large extent of cultivation, with very few disputes.

The great defect in this system is that, if only a small quantity of water comes down, the dams lower down the stream go without, and if a large quantity comes down the violence of the torrent is too great, whereby the temporary dams are carried away in succession too rapidly, and a large quantity of water is wasted. If masonry dams were established in these places the water would be stored up for future use in the bed of the river. For example, in a creek 15 feet deep with a fall of 20 feet per mile, if dams were constructed every ¾ of a mile the surplus water passing over the tops in succession a series of still-water canals would be formed, whence the water could be drawn by smaller channels. By a proper application of this method there is little doubt that a great extent of country in this Colony now lying barren could be brought under irrigation.

I

I regret that my duties in connection with the Calcutta Exhibition did not admit of my visiting the irrigation works of India before the season was too far advanced for extended inspection, and that from the same cause I was unable to go over the Madras and Bombay systems. But in the interest of future operations in the conservation of water in this Colony it would be of great service if a detailed report on works applicable here could be obtained from those provinces.

I have, &c.,
F. A. FRANKLIN.

REPORT ON RIVER-GAUGES, SHOWING LIST OF PRESENT AND PROPOSED SITES.

To the Secretary of the Commission,—

Sir, Sydney, 6 January, 1885.

I have the honor to report that, in accordance with verbal instructions received from the President, I have made inquiries regarding the most suitable sites for river gauges, and as the result of these inquiries I beg to submit a list showing the places at which gauges will be most useful on the various rivers of the interior.

2. While preparing the list I consulted Mr. Russell, the Government Astronomer, and Mr. Moriarty, Engineer-in-Chief for Harbours and Rivers, and obtained valuable information from them. The gauges on the Macquarie, Peel, Namoi, and Talbragar, are entered in the list, on the suggestion of Mr. Russell. Mr. Moriarty very kindly supplied me with a copy of a river gauge book which was prepared by him in 1864. The positions of suitable road bridges were obtained from Mr. Bennett's Department.

3. In order to obtain a connected record, the positions of the gauges relatively to Sydney high-water-mark should be determined. A table of discharges, corresponding to various readings of the gauges, should also be prepared.

4. With a few exceptions the discharges hitherto calculated have been only rough approximations. As the determination of the discharges of the rivers, and particularly the minimum discharges, is a matter of great importance, I beg to recommend that this question of gauges and discharges should receive early consideration, and that the necessity for sanctioning the expenditure required for fixing the gauges without delay should be brought to the notice of Government.

5. In addition to the list of gauge sites and the gauge book supplied by Mr. Moriarty, I append a gauge register sheet for daily observations, which I recommend for adoption. It is very similar to the rain-gauge register sheets supplied to observers by Mr. Russell. Owing to the increase of population and the spread of settlement, daily readings can more easily be obtained now than weekly readings at the time Mr. Moriarty's register book was prepared.

I have, &c.,
H. G. M'KINNEY, M.E.,
Engineer to the Commission.

River Gauges—List of present and proposed Sites.

No. of Gauge for each River in order.	River.	Proposed Sites of Gauges.	Bridges available for fixing Gauges.	General Remarks and Explanations.
1	Snowy River ...	.....		The available information regarding the Snowy River is not sufficient to enable me to suggest a site for a gauge.
1	Murray River...	Dora Dora		
2	Do ...	(L) Albury (R)	Railway Bridge & Road Bridge.	
3	Do ...	(H) Howlong	Timber Road Bridge.	
4	Do ...	(H) Wahgunyah or Corowa ...	Do do	
5	Do ...	(H) Mulwala (R)		
6	Do ...	(H) Tocumwal		
7	Do ...	(L) Moama (R)	Railway Bridge on iron cylinders.	
1	Edward	(L) Deniliquin.....	Timber Road Bridge.	
1	Murrumbidgee...	(L) Gundagai	Road Bridge on iron cylinders.	
2	Do ...	(L) Wagga (R)	Railway Bridge & Road Bridge.	
3	Do ...	(L) Narrandera	Railway Bridge on iron cylinders.	
4	Do ...	(L) Hay (R).....	Road Bridge on iron cylinders.	
1	Lachlan	(L) Cowra	Timber Road Bridge.	
2	Do	(L) Forbes	Do do	
3	Do	(L) Condobolin	Do do	
4	Do	Hillston		
5	Do	Oxley	Road Bridge on 5" screw piles.	
1	Murray—Murrumbidgee—Lachlan.	(H) Euston (R)		At the places marked "(L)" the gauges will easily be connected with the railway levels.
1	Murrumbidgee—Lachlan.	(H) Balranald (R)	Road Bridge on iron cylinders.	It may not be practicable to level to the remaining sites at the time of fixing the gauges; but the gauges should eventually be levelled in every case, as, until this is done, the observations though useful will lack completeness and continuity.
1	Talbragar.....	Brocklehurst	Timber Road Bridge.	
1	Macquarie	(L) Dubbo	Railway Bridge.	
2	Do	Warren.....	Timber Road Bridge.	
1	Peel—Namoi ...	(L) Tamworth.....	Bridge.	
2	Do ...	(L) Gunnedah	Do	
3	Do ...	(L) Narrabri	Timber Bridge.	
4	Do ...	(L) Walgett.....	Timber Bridge over the Namoi.	
1	Macintyre—Barwon—Darling.	Goondiwindi	Timber Road Bridge.	While the list includes the sites at which gauges are most necessary, other gauges would be useful, and records kept by private observers would be worthy of note.
2	Do	Mungundi	Do do	
3	Do	(L) Walgett.....	Timber Bridge over the Barwon.	
4	Do	(L) Bourke (R)	Road Bridge on iron cylinders.	
5	Do	(L) Wilcannia (R)		
6	Do	(H) Menindie (R)		
7	Do	(H) Pooncarie (R)		
8	Do	(H) Wentworth (R) ...		
1	Murray—Darling.	Moorna.....

Observer.

In the column of remarks, any trustworthy information regarding the changes of level during the interval between the gauge readings should be briefly noted; also particulars of any considerable accumulation of silt in the locality. Such information should, if possible, include the time of the beginning or end of any rapid rise or fall of the river. Any heavy fall of rain should also be noted.

(By Authority) H. G. M'KINNEY,
Engineer to the Commission.

REPORT ON RAILWAY AND OTHER LEVELS IN THE INTERIOR OF THE COLONY.

To the Secretary of the Commission,— Sydney, 15 January, 1885.

Sir,

In accordance with verbal instructions received at the last meeting of the Commission, I have the honor to submit the accompanying report, which is based almost entirely on levels received from the Railway Department and from the Department of Harbours and Rivers.

2. Next to the fixing of gauges and the determining of the supply in the rivers, I consider that the two sets of levels recommended in the report are the most necessary field work in connection with water conservation on a large scale in the interior of the Colony.

I have, &c.,
H. G. M'KINNEY, M.E.,
Engineer to the Commission.

(A.) The levels taken by the Railway Department and by the Department of Harbours and Rivers afford only a general idea of some parts of the Colony, and conclusions arrived at from them can only be considered as approximate. Bearing this in mind, the available information permits of the following deductions:—

1. That the fall from the place where the Billabong Creek is crossed by the Great Southern Railway to Jerilderie is over 300 feet, or at a mean rate of more than 4 feet per mile; also, that from Jerilderie to the junction of the Murray and Murrumbidgee the fall is about 170 feet, which is at the rate of about 13½ inches per mile.
2. That the country between the Murray and the Murrumbidgee must be regarded as two main doabs and not one, the Billabong Creek representing the intermediate river.
3. That so far as levels are concerned, the Billabong Creek could be supplied from the Murray as well as from the Murrumbidgee.
4. That the levels of the country are not sufficiently known to enable any one to state positively that high level canals commanding large areas could be constructed, but that all the evidence available goes to show that such canals could be carried out from both the Murray and the Murrumbidgee.
5. That the flood-water of both rivers can be utilized to some extent; that of the Murray in the Edward River and the creeks flowing into it, and that of the Murrumbidgee in the Yanko, Columbo, and Billabong Creeks.
6. That the practicability of useful work in this part of the country is so assured that cross sections from the Murray to the Murrumbidgee should be taken at every 5 miles, with a view to determining the nature of these works.

(B.) In the district between the Murrumbidgee and the Lachlan very few levels have been taken, and the information available from all sources is very meagre. The only conclusions justifiable regarding water conservation in this district are:—

1. That it is improbable that flood-water from either the Murrumbidgee or the Lachlan can be conveyed to any great distance in the interior of the district.
2. That the flood-water from both rivers can be utilized to some extent by diverting it into creeks and natural depressions in the low land near them.

(C.) Taking into consideration the great extent of country between the Lachlan and the Darling, but little information of a definite nature is available regarding it. There is, however, sufficient to lead to the following conclusions:—

1. That the Willandra Billabong is a great natural inundation canal, which should be surveyed and levelled with a view to its improvement.
2. That there are unusual natural facilities for utilizing the flood-water of the Darling in creeks, ana-branches, and lakes, particularly in the portion of the river south of Wilcannia; and that on this account a line of levels should be taken along the Darling, and branch lines from it to the lakes and large natural depressions.
3. That it is improbable that any supply of water can be taken from the Bogan in the direction of Cobar.
4. That the Macquarie could probably be diverted into the Bogan.
5. That the fall from Narrabri to Walgett is about 260 feet. The direct distance being about 100 miles, the fall in the country in the direction of the river is slightly over 2½ feet per mile.

(D.) No connected levels have been taken in the country beyond the Darling.

H. G. M'KINNEY, M.E.,
Engineer to the Commission.

FURTHER REPORT ON LEVELS.

To the Secretary of the Commission,—

Sir, Sydney, 22 January, 1885.

In continuation of my report of 15th instant, and in accordance with verbal instructions received on that date, I have the honor to furnish, for the information of the Commission, plans showing a number of levels obtained from the Railway Department and from the Department of Harbours and Rivers.

2. The scale of the plans does not permit of the entry of levels at less intervals than 2 miles, but those which have been entered will give a fair general idea of the slope of the country on the various lines on which they are marked.

3.* The Railway Department cannot give any information about the trial line to Wilcannia, as the books and sections have not yet arrived in Sydney. This information will be available in about a month.

4.* The Deniliquin and Moama Railway Company has been asked for information regarding the levels of the country along that line, but a reply has not yet been received. 5.

* The levels to Wilcannia have since been received from the Railway Department, and the Secretary to the Deniliquin and Moama Railway Company has courteously supplied a list of levels of the country along that line of railway. In both cases the information so obtained has been summarized and shown on the map of the Colony appended to the Report.—H.G.M'K.

5. Under these circumstances, I can add to my report of 15th instant only the following items of information:—

A. That the town of Cobar is 200 feet above the flood-level of the Bogan at Nyngan.

B. That at 58 miles from Nyngan and 22 from Cobar the Railway line crosses a ridge at an elevation of nearly 500 feet above the flood-level at Nyngan.

6. The levels now supplied include all those of the western plains which are at present available.

I have, &c.,

H. G. M'KINNEY, M.E.,

Engineer to the Commission.

REPORT ON THE TANTANGARA BASIN, UPPER MURRUMBIDGEE.

To the Secretary of the Commission,—

Sir, Cooma, 15 March, 1885.

In pursuance of instructions received, I have the honor to transmit herewith a plan showing traverse and section, also cross sections and contour line on west side of part of the Murrumbidgee River, in the parish of Tantangara, county of Wallace.

I have to observe that, on arriving at the locality, I found that the area of water to be impounded, unless by a dam of exceptional height, was much less than my impressions (of sixteen years since) led me to suppose; but I have executed such survey as I considered desirable, in order to place before the Commission such an amount of information as would guide them in forming an opinion of the value of the site for storage purposes. I did not consider myself justified, under the circumstances, in entailing further outlay.

From the plan* it will be seen that, with a height of 83·09 feet above water level at C, there will be a height of 44·66 feet at J, the junction of Currangorambla Creek and the Murrumbidgee River; the direct distance between these points is about (by scale) 272 chains, and the average fall per mile is 11·3 feet; with this proportion the contour line, if produced, would extend up the Murrumbidgee above its junction with Currangorambla Creek about 3¼ miles.

With a view to the possibility of the water being retained by a series of low dams I have shown a section of the river at T, where I observed there would be a natural by-wash. I may point out that from this point of the river upwards there are, I believe, many suitable points for the erection of dams, so that the whole bed of the river may be made a reservoir.

On my arrival at Tantangara there had then been but little rain for some time; the river was then running at the rate of (I estimate) 2 miles per hour, with an average depth of 6 inches at or about the point C; while there very heavy rains fell, but the river did not rise more than 2 or 3 inches, and the water was but slightly discoloured; there are no evidences of scour, nor is there any drift or timber brought down by flood-waters from the head of the river to the Gulf. I am informed by old residents that in high floods (for the locality) the river is crossable on horseback at and above the point D, shown on plan; that during the past, and in all seasons, the river maintains an even flow during the summer of about the delivery estimated in the former part of my letter. The whole country towards the head of the river is of a spongy nature (in flat lands), and two very constant streams, Nungar and Tantangara Creeks (also flowing from swampy country), flow into the river. There are, I believe, many minor streams of same character running into the river above the junction of Tantangara Creek and Murrumbidgee River.

While in the locality I inspected Currangorambla Creek for some distance up its course, at the south-west corner of portion 2, parish of Currangora, county of Cowley. I observed there was a site for a dam, with a natural by-wash to the east; above this point the bed of Currangorambla Creek (which flows slowly) opens out, and I am of opinion that a large amount of water could be impounded.

I will draw the attention of the Commission to the question as to whether a series of low dams from the Gulf upwards to the head of the Murrumbidgee River and tributaries would answer the purpose of conserving the water to a valuable extent.

I made inquiries as to whether stone for building purposes could be obtained; and I find that large quantities of basalt, in long lengths, can be obtained about the junction of Tangangara Creek with river; limestone can be obtained within a few miles; there is also an abundance of clayey loam in the immediate vicinity of the Gulf.

I have, &c.,

CORNELIUS HAYLOCK,

Licensed Surveyor.

REPORT ON MR. HAYLOCK'S SURVEY OF THE TANTANGARA BASIN, UPPER MURRUMBIDGEE.

8 April, 1885.

Although, in his report, Mr. Haylock expresses disappointment with the Tantangara Basin, I do not think that his report and plan are by any means discouraging. Mr. Haylock's plan and sections show that with a dam having a mean length of about 300 feet, an extreme height of about 84 feet, and a mean height of about 60 feet, the water of the Murrumbidgee would be thrown back to a distance of about 6½ miles. So far as I can judge from the plan, it seems probable that the reservoir so formed would average 40 feet in depth throughout a width of a third of a mile. The quantity of water thus impounded would be 2,416,000,000 cubic feet. If the gap at the lower end of the Tantangara Basin would afford a good foundation for a dam of masonry or concrete, such a dam could be built at a cost of about £40,000. The rate which the water impounded would cost would thus be 3,020 feet for one shilling. This rate is too high to admit of the use of the water for ordinary irrigation purposes; but it is very probable that the capacity of the reservoir is here understated, as several creeks flow into the Tantangara Basin, the valleys of which would afford considerable storage.

It would appear from Mr. Haylock's report that the discharge of the Murrumbidgee at Tantangara was about 183 cubic feet per second at the time of his survey.

Considering that the Tantangara Basin would, on a low estimate, contain sufficient water to give a supply of 200 cubic feet per second for 140 days, I think that, although the cost of storage (judging from the information available) seems high, the basin is well worthy of a more complete examination.

H. G. M'KINNEY, M.E., M.I.C.E.,

Engineer to the Commission.

REPORT

---

* The plan is retained in the office of the Commission.

REPORT ON THE RIVER MURRUMBIDGEE AS A SOURCE FOR CANALS.

8 April, 1885.

Along the course of the Murrumbidgee the country may be considered mountainous as far as Wagga. Regarded as a source of supply for canals, this river is very similar to the Murray, and similar difficulties would attend the construction of canals above the point where it reaches the open plains. The time at my disposal did not permit me to follow the course of the river throughout the length between Gundagai and Wagga, but I examined the plans in the office of the District Surveyor, and obtained much valuable information from that gentleman in reply to questions which I put to him. In consequence of information so obtained I saw the advisability of visiting the Malibo Range, and the District Surveyor very kindly undertook to drive me to it. The Malibo Range is about 6 miles by road from Wagga, and is the last range which crosses the river before it emerges into the open country. The width of the gap through which the river flows appears to be under half a mile. The Malibo Range occupies the same position on the Murrumbidgee as the Jindera Range on the Murray. Both places are favourable sites for weirs; but that on the Murrumbidgee is at the narrower gap, and a weir there should be less expensive than on the Murray.

From the "summer level" at Wagga to the ground level at the junction of the Yanko and Colombo Creeks there is a fall of 138 feet. The rate of fall in the Murrumbidgee, near Wagga, is under 1 foot per mile; it would therefore be practically correct to assume that the summer level at the Malibo Range is about 128 feet above the ground level at the head of the Colombo Creek. As the distance is about 56 miles, the fall is at the rate of over 2 feet per mile.

With regard to the available supply, my instructions in regard to taking discharges did not include Wagga, so that I cannot state the discharge there; but at Gundagai I found that it was 630 cubic feet per second. It is evident, under these circumstances, that the prospect of a remunerative permanent canal from the Murrumbidgee, as well as from the Murray, is most promising. Before entering more fully into the subject, it will be necessary to make a further examination of the river and take the discharge at Wagga.

On the subject of inundation canals from the Murrumbidgee, some time ago, in my report to the Commission regarding the Yanko Creek, I pointed out that that creek must be considered as an inundation canal. My instructions then did not include a complete examination of the Yanko Creek, but related merely to improvements near its head. I hope that the improvement of the entire creek will yet be taken up, as I think that in every case such a work should be dealt with as a whole.

In addition to the Yanko, I have reason to anticipate that at least two other useful canals of the same description can be made to carry a supply of flood-water from the Murrumbidgee at a moderate cost. I think it is better, however, to postpone entering into detail till I am in possession of more complete information.

In conclusion, I have only to add that, while I confidently anticipate that canals will be found to be practicable in the district between the Murrumbidgee on the north and the Billabong and Edward on the south, still I think that a further examination of the Murrumbidgee is necessary in the first place, in order to determine the lines which the survey for such canals should take.

H. G. M'KINNEY, M.E., M.I.C.E.,
Engineer to the Commission.

REPORT ON THE RIVER MURRAY AS A SOURCE OF SUPPLY FOR CANALS.

8 April, 1885.

In considering the question of tapping the Upper Murray, there are two arrangements which suggest themselves. The first is to carry the supply along the Murray Valley, at an increasing elevation above the river, till a place is reached at which the canal could leave the valley and take a north-westerly direction to the open plains. The second arrangement is to draw the supply from some point at such an elevation that the water could be carried through or over the dividing range between the watershed of the Murray and that of the Upper Billabong.

The investigations which I have already made, together with the past records regarding the supply in the Murray, afford ample evidence that the available discharge is sufficient to warrant the construction of a canal, if such a work were proved to be practicable.

The supply then being available, the next point to consider is the nature of the river valley. From examination of the plans in the Office of the District Surveyor in Albury, from inquiries which I made of that gentleman, as well as of Mr. Basil Gray and others who know the district thoroughly, and, lastly, from my own observation of the river up to 12 miles from Maraket, I came to the conclusion that there was no chance of constructing a canal beyond the Seven-mile Creek, so that it was unnecessary for me to go beyond that point in my inspection.

From the Seven-mile Creek down to some distance below Wagra the river valley varies generally from half a mile to three-quarters of a mile in width. The hills are steep, and in most cases of granite. Their slopes are rugged, with out-cropping rocks, and the soil consists chiefly of loose and porous granite detritus. The soil at the foot of the hills is of the same composition, while that in the river valley proper is a light, sandy, alluvial deposit. The porosity of the soil is at once apparent; but, in addition, substantial evidence of this is afforded by the numerous surface springs, and by the manner in which the water flowing in some of the small watercourses appears and disappears. The river follows a tortuous course along its valley—sometimes washing the base of the hills on the New South Wales side, and sometimes passing close to those on the Victorian side. The rate of fall in the Murray near Albury, and on the up-stream side of the Union Bridge, is under 2 feet per mile, while at Dora Dora, which is 40 miles by road above Albury, the rate of fall is scarcely 3 feet per mile. From inquiries which I made, and from my own observations, I have no doubt that for the purpose of a preliminary investigation such as this, it would be safe to assume that the mean rate of fall from Dora Dora to Albury is not more than 2½ feet per mile.

The

The various points enumerated show that the valley of the Upper Murray is very ill-adapted for canal construction. The hills are steep and rugged, and come in some cases close to the water's edge; the rocks are of the hardest description; the soil, as a rule, is of an unsatisfactory character, and the fall in the river is so slight that any gain in head which could be obtained would be acquired at a cost absolutely prohibitive. The idea of tapping the Upper Murray and bringing a supply down the river valley may therefore be dismissed as impracticable.

With regard to the second arrangement for obtaining a supply from the Upper Murray, namely, by carrying it through or over the watershed dividing the Murray from the sources of supply of the Upper Billabong, examination of the plans in the Office of the District Surveyor at Albury was sufficient to show that if it were possible to carry out this project the canal head would require to be between the Dora Dora Station and the Seven-mile Creek. Beyond the latter place the distance of the Murray from the watershed of the Billabong increases, while there is no increase in the rate of fall in the river. For this reason I selected Dora Dora as the place for ascertaining the discharge and the rate of fall of the Upper Murray. As already stated, the rate of fall in the Murray from Dora Dora to Albury may safely be taken at 2½ feet per mile. The distance by road is about 40 miles, and by river about 80 miles. The reduced level of the surface of the Murray at Albury was 490, so that when I measured the discharge at Dora Dora the reduced level there could not be much over 690. The flood level of the Billabong at Culcairn is 694, and the bed level of the creek at the same place is 673. The distance of the Murray opposite Basin Flat from Culcairn is over 30 miles in a direct line, and the intervening country is mountainous throughout. Although the estimated reduced level of the river at Dora Dora must only be regarded as approximate, it is abundantly evident that the Woomargama Creek, which is a mountain stream flowing into the Billabong from within a few miles of Dora Dora, must be at a much higher level than the Murray, and therefore could not be utilized in carrying a supply to the Billabong. Yet this Woomargama Creek is in a more favourable situation than any of the other sources of the Billabong for the purpose of carrying a supply from the Murray. It is also clear that if it were possible to divert a supply from the Upper Murray to the Billabong—which is extremely doubtful—tunnelling would be required on such a scale as to make the undertaking altogether impracticable.

The points which have been advanced to show the impracticability of canals from the Upper Murray as far as the Seven-mile Creek would hold with much greater force in regard to the portion of the river beyond that place. Still, as the main objection to the idea of diverting the Upper Murray into the Billabong arises from the want of sufficient fall from the Murray, and as the levels of the Upper Murray have only been deduced approximately, I think it would be advisable to place the matter beyond dispute by levelling the Dora Dora from the Railway Station at Bowna.

Although there would be an advantage in diverting the whole available supply from the Upper Murray, still the main purposes of drawing a permanent supply from that river can be gained without the expense of carrying a canal through difficult and hilly country. I believe it will be found that the first, and probably the only place on the Murray at which a permanent canal can be taken off at a remunerative cost, is situated on the Bungownah, or Bungowannah Run, at the end of the Jindera range of hills, and near the boundary of the counties of Goulburn and Hume. At the place where the river meets these hills it flows in a north-westerly direction and close to the foot of the range, which is here steep and rocky, with rough masses of granite cropping out over the hill face, and granite boulders forming the river bank. As it emerges from the range the river turns off almost due west, having an alluvial flat of increasing width on its northern side. At this place, where the river changes its course, there is a bar of pebbles forming a rapid, the difference of level above and below the bar being about 6 inches. This bar is at the place at which I think a weir can be constructed with advantage to throw a supply along a canal, which for a short distance near the head would follow the line in which the high ground meets the alluvial flat. The length of the weir proper would be only about 250 feet; but protective works might be required at some places on the low land, extending to the foot of the hills on the Victorian side of the river. The banks of the river were from 12 to 13 feet above the surface of the river at the time of my inspection. By using a movable weir, which would remain raised only while the supply in the river was low, and which would lie flat in the river-bed during floods, I believe it would be quite practicable to obtain a permanent supply without interfering with the flood levels.

The points in favour of the proposed site are as follows:—1st. It is at the last range of hills, with only open plain country beyond, so that there would be no rock excavation and no difficult country to pass through. 2nd. The river valley is at this place moderate in width and bounded by hills. 3rd. The depth of cutting, so far as can be judged without a survey, would be comparatively slight from the outset.

The distance of the Jindera hills from Albury by river cannot be more than about 10 miles, and the fall in that length is at the rate of about 1 foot per mile. The reduced level of the water surface, as I found it, must therefore have been 480, or very nearly so. The reduced level of the country around Jerilderie may be taken as 361, and that at Deniliquin as 289. The former place is 78 miles, and the latter 111 miles, from the proposed canal head. From the Murray at Jindera hills to Jerilderie there is therefore an average fall of more than 18 inches per mile, and between the same place and Deniliquin a fall of nearly 1 foot 9 inches per mile. As the fall of the country is regular and in a westerly and north-westerly direction, the conditions are remarkably favourable for the construction of a permanent canal for irrigation and water supply in the upper portion of the district between the Murray and the Billabong Creek.

In considering the discharging capacity which should be adopted for such a canal, the question whether the navigation of the river can be interfered with at once suggests itself. Navigation as far as Albury is considered practicable when the height on the old gauge there is at least 4 feet, that is when the surface of the river there is about 494 feet above sea-level. The discharge at Albury at the time of my visit was nearly 1,200 cubic feet per second, and the river was only 490·21 feet above sea-level. If a canal carrying 1,000 cubic feet per second were constructed, the navigation level would probably be raised to 7½ feet on the gauge. The question as to the effect on the navigation at Echuca and other places could not be determined without further investigation into the sections and discharges at those places. I have not at present any means of estimating the value of the navigation which would be lost through the abstraction of such a supply; but, in regard to the advantages which would be acquired, I may mention that 1,000 cubic feet per second should irrigate about 200,000 acres of land, and as £1 per acre per annum would not be an excessive rate, the gross revenue arising from the distribution of that quantity of water would

be

be £200,000 per annum. A canal having a bed width of 62 feet, slopes of 1 to 1, a depth of 6½ feet of water, and a fall of 1 in 5,000—that is slightly over 1 foot per mile—would discharge the quantity assumed.

In connection with the available supply there is still another question, namely, whether the quantity of water flowing into the Murray, in the Mitta Mitta and Little Rivers, can be depended on. This also is a matter requiring further investigation.

On the whole there is a strong probability that a remunerative permanent canal can be constructed from the Murray at the place mentioned. For the design of such a canal, accurate surveys and levels, carried out on a comprehensive scale and in a systematic manner are indispensable.

The canal which has already been discussed would carry a permanent supply, and utilize the whole available portion of the minimum discharge of the Murray near Albury. In addition to this, I have ascertained that much can be done in saving flood-waters by means of what in previous reports I have termed "inundation canals." The first place at which there appears to be any prospect of such a work being practicable is at Howlong. The hills on the New South Wales side of the river gradually become lower and more distant till Howlong is reached, and there they almost entirely disappear. Near Howlong, and extending in a direction approximately parallel to the river, there is a valley, or rather depression, between the river and the hills. This valley is separated from the river by a ridge along which a ridge passes from Albury to Corowa. At Howlong there is a low and narrow place in this ridge, where it is said that in extraordinary floods the water passes over into the valley beyond. It is also alleged that in high flood a channel called the Twelve-mile Creek receives a supply from the Murray through a lagoon at Howlong, and that in exceptional cases the flood-water passes along this creek to the Billabong at about 10 miles from Jerilderie. Some of the farmers at Howlong believe that if the ridge were cut through, a supply could be obtained from the river in ordinary floods at very little expense. This is doubtful, but the question is worth further investigation.

From Howlong to beyond Corowa the high land bordering on the alluvial flats, through which the Murray flows, appears to range from 30 to 40 feet above the ordinary low supply in the river. It seems very improbable that any supply of flood-water can be drawn from the Murray throughout this distance.

Between Corowa and Tocumwal the level of the country becomes lower relatively to the river, and the colour of the soil becomes darker. In the neighbourhood of Tocumwal the ordinary surface of the river is only about 10 or 12 feet below the surrounding country, and the township is situated on the only piece of land which is not liable to be covered in high floods. Here the practicability of inundation canals on an extensive scale is beyond question. The river banks, as already stated, are low, the surface of the surrounding district is remarkably uniform, and the ground has a steady fall from the river in a north-westerly direction. Beginning at Mr. M'Farlane's Baruga Station, and about 8 miles up-stream from Tocumwal, there is a series of creeks into which the flood-water of the Murray occasionally flows. It is not unlikely that the levels and surveys will show that several of these creeks can be utilized with advantage; but so far as I could ascertain in the limited time at my disposal, the Tuppal Creek will be the most easily dealt with in proportion to the benefits it will confer. Commencing as an ill-defined depression in the ground at the bank of the Murray, about 2½ miles down-stream from Tocumwal, the Tuppal Creek becomes deeper and better defined, till at 12 miles from Tocumwal its depth is about 12 feet and its top width about 35 feet. This creek is here very similar in appearance to the Yanko, to which it is in other respects a counterpart, as its relation to the Murray corresponds exactly to the relation which the Yanko Creek bears to the Murrumbidgee. There is, however, a difference in regard to the manner in which the Tuppal receives the flood-water. When the surface of the Murray at Albury is 9 or 10 feet above what is then termed "summer level," no supply is received into the Tuppal Creek at its head; but the flood-water passes into it through several small creeks near Wopperana. The most important of these small creeks are the Narangi, Tuppal, and the Native Dog Creeks. Before the flood-water will pass into the Tuppal Creek at the head, the height on the gauge at Albury must be 12 feet or more, that is, the reduced level of the surface of the river at Albury must be about 502. Mr. Brown, the owner of the Tuppal Run, was so confident of being able to obtain a good supply from the head of the Tuppal Creek in ordinary floods, that he endeavoured to secure the co-operation of his neighbours and carry out the necessary work as a private enterprise. I think it is better that this arrangement was not followed out, as it is improbable that anything more would have been aimed at than providing a partial supply in the first 20 or 30 miles of the creek. That the question is one which merits treatment on a comprehensive scale is at once evident, when it is considered that the fall from the flood level at Tocumwal to the ground level at Deniliquin is 77 feet, and from the latter place to the junction of the Murray and Murrumbidgee 100 feet, and that the fall, as far as can be judged, is regular.

After examining the levels which I compiled for the Commission from the plans and records in the Government Departments, I ventured to give the opinion that there was then sufficient information to warrant the expense of a complete set of cross sections of the country between the Murray and the Murrumbidgee. In this report I have dealt only with that portion of the country between the Murray on the south, and the Billabong Creek and Edward River on the north. The paramount importance of canals in this district is indisputable, and I think I have shown clearly that the practicability of constructing them is beyond question. Under these circumstances, and considering the extent to which this part of the country is sometimes devastated by droughts, I think the necessary surveys and levels should be commenced without delay. It is almost unnecessary for me to add that the more complete and comprehensive the surveys are made, the less will be the first cost and the subsequent maintenance of any works which may be undertaken.

H. G. M'KINNY, M.E., M.I.C.E.,
Engineer to the Commission.

REPORT

REPORT ON THE NAMOI RIVER.

To the President and Members of the Commission.

Gentlemen, Sydney, 15 April, 1885.

In accordance with your decision, at a meeting of the 19th March, I have inspected the Namoi River in the neighbourhood of Gunnedah and Narrabri, with special reference to certain sites for the conservation of water, suggested by Mr. T. K. Abbott, S.M., in his evidence before the Commission in October last, and I have the honor to forward you my report thereon.

Reservoir site, No. 1.

The first site examined is situated at a point on the Namoi River about 2 miles from Carroll, where a spur from a conspicuous conical hill strikes the right bank of the river. This spur would form the western extremity of the proposed dam, whilst the eastern end would abut on a long spur about 2 miles from the opposite bank of the river. The banks are steep, and vary in depth from 20 ft. to 30 ft., and the channel is about 50 ft. wide. The country between the above spurs and on the site of dam is almost level, and is composed of post tertiary alluvial drifts which have not been bottomed. Wells have been sunk on this plain to a depth of 30 ft., when a constant and ample supply of water for stock and household purposes was tapped. A brief inspection of this position satisfied me that it was unsuitable for a dam, because of the great distance of deep permeable country between the bounding spurs.

Reservoir site No. 2.

The next site I inspected is situated in a gap in one of the numerous ridges crossing the country in this vicinity, and in proximity to the western boundary of the parish of Yarrari. This gap is about a mile wide, and is intersected by the Tulcumbah Creek. A hard conglomerate spur immediately approaches the left bank of the creek, and dips under it apparently on the line of strike at an angle of 10 degrees. The country rises very gradually till it meets the opposite spur, which consists of porphyritic rock. The country between the spurs is composed of deep alluvial drifts, which have been proved by two wells sunk at some distance apart and on each side of the gap to be over 140 feet deep. There is therefore the same insuperable objection to dam constructions in this position as before in the first site.

Reservoir site No. 3.

The third position I examined is situated on the Namoi River, about 1½ mile north-west of Mr. Winter's head station, and in the parish of Namoi, about 7 miles by river course above the junction of the Peel River. At this point the Namoi has cut through a bold ridge of hard conglomerate, which forms steep banks on either side. (*Vide plan in accompanying portfolio.*) At about 100 yards higher up the river it is flanked by a basaltic dyke, which separates it from a hard blue encrinital limestone belt traceable for miles, at times forming conspicuous and detached ridges or spurs, and at times, as in this instance, sinking so as only to be just visible above the surface of the ground. This narrow gorge offers many advantages for the construction of a dam. Its base and extremities would be embedded in the solid rock of the above ridge, which appears to terminate the divide between the Namoi and Peel Rivers. A dam 75 feet high would only measure 115 feet across at base, and 812 feet across at top. There is abundance of material in the vicinity for its construction. It would require to be an overshot dam, to provide for the contingency of an extensive flood discharge; consequently it would have to be constructed of solid masonry in cement, or on the same principle as the mining storage reservoirs in California. Such dams have proved very successful there to a height of 70 feet, at a cost of only 12s. per yard. They consist of dry masonry, lined in front with 3-inch planking to prevent leakage. The faces are built up by hand, and the interior filled with stone thrown in promiscuously. The outlet could be formed by a tunnel piercing the spur on the right bank of the river, and the by-wash by a cutting of about 20 feet in a depression of the ridge, about a mile from the left end of the dam.

Advantages.

Such a dam would throw the river back about 13½ miles, and would enclose a large basin, which, judging from Mr. Higinbotham's partial survey, would impound over 10,000 million gallons of water. Thus all the conditions for the construction of an extensive reservoir at this position appear highly favourable, especially as regards the position of the dam and the facilities for its construction at a moderate cost, as also regards the natural advantages for a capacious by-wash and outlet tunnel, and the firm impermeable bed generally of the basin it would enclose.

Objection.

There is, however, one grave objection to such a project, in the deposition of silt during floods and freshes. From reliable authority I am led to conclude that this deposit is enormous. Some are of opinion that it could easily be prevented from accumulating by a large sluice in the dam or outlet tunnel. But any such attempt to provide for the discharge of flood-waters would be hazardous, very costly, and would in every probability prove a failure. Further, any fresh as it met the rim of the reservoir would at once begin to lose its velocity and to deposit silt. Such a dam, therefore, in the course of a few years would completely alter the present *régime* of the river, gradually raising its bed and necessitating expensive works for its restoration to primal conditions.

Objection modified.

This difficulty might be considerably modified by constructing a series of similar impounding reservoirs at different intervals higher up the river, or where opportunity offered in the surrounding watershed, for which, according to report, the country offers unusual advantages.

Reservoir site No. 4.

About 6½ miles higher up the river I examined another basin, formed by two low spurs running from the dividing ridge of the Peel and Namoi River, which converged as they approached the latter river. A dam 30 feet high at this spot would enclose a fine flat, with steep bounding sides fully 3 miles long and half a mile wide. The converging spurs on which it would abut apparently consist of a brownish, close-grained Devonian sandstone, tilted at an angle of 30 degrees. As the rock was exposed in the water-course representing the outlet to the river, a sound foundation for a dam would probably be found right across. As no survey has been made of this valley I am unable to furnish further particulars as to its value for conserving water. Mr. Higinbotham's levels of the previous reservoir show, however, that a large portion of this basin would be included within its area, whilst, if the dam were increased in height to 85 feet, the whole of it would be covered with deep water.

Particulars of Namoi River and valley.

The average width of the bed of the Namoi River in this district is about 40 feet at bottom and 180 feet at top. It has steep banks, which vary from 15 feet to 25 feet in height. Its declivity averages 5 feet per mile. Its present discharge is estimated at 45,360,000 gallons per diem. Its highest flood-mark is about 40 feet from bed. Its bed is chiefly filled with gravel and sand, whilst its banks are composed of clay, gravel, and sand, in varying proportions according to depth. In its course to Gunnedah it intersects numerous rocky spurs, where it exposes the strata on either side. The whole country appears to have been subjected to violent igneous eruptions, as shown by the frequent dikes of porphyry and basalt,

which account for its broken character and for the numerous cross spurs and ridges. In places the sandstones and schists appear tilted at a very high angle and completely metamorphosed, whilst in other places they are soft and more evenly bedded, but rarely dip at a less angle than 20 degrees.

Turrawan waterhole.

After staying in this neighbourhood for two days I proceeded to Narrabri, to examine a large waterhole on the Namoi River in the neighbourhood of the township of Turrawan. This waterhole, or rather pine reach in the river, is very deep, is about 3¼ miles long, and has an average width of about 300 feet. The banks are steep, and are about 20 feet deep. At the upper end on the right bank there is an outcrop of hard tertiary sandstone with ferruginous bands, which has a very slight northerly dip. There is no indication of rock on the opposite bank, but about half a mile higher up a rocky sandstone spur abuts right on the left bank. At the lower end the right bank appears to be alluvial, mixed largely with gravel, whilst the left bank is formed by a shelvy beach of almost pure gravel, offering an imposing obstacle to the construction of a weir or dam; besides which, the country being higher on both banks there is no facility for an off-take.

Spring Creek basin.

Having heard of a probable site for a large reservoir at the mouth of Spring Creek, about 20 miles north of Narrabri valley, as its watercourse debouches from the mountain ridges, I spent another day in examining this locality. I found the country covered with dense scrub on both the ridges which flanked the valley, and also in the valley itself, consequently it was impossible to judge as to the capacity of the basin, or the length of dam required to impound it. Spring Creek heads in the Nandewar Range, which forms the main divide between the Namoi and Gwydir Rivers. This range takes a zigzag south-easterly course, and finally abuts on the main Cordillera, a few miles south of Uralla. After leaving the mountains the creek flows through a rich plain, which has a gradual fall towards the Namoi of about 20 feet per mile. Nearer its source it is enclosed by high rugged ridges, which rise over 1,500 feet above the plains. Two long spurs from either ridge converge at the mouth of the valley, and offer certain advantages for a dam. The valley behind opens out to a flat of some extent, but without survey it is impossible to estimate the area of the basin which would be enclosed, or the quantity of water it would conserve. I

Maule's Creek.

was informed that there was another fine site for a reservoir at Maule's Creek, about 30 miles from Narrabri, and which I recommend should be examined at some future opportunity.

Nandewar Range.

The whole aspect of the country on the southern flank of the Nandewar Range is distinctly volcanic, and, owing to the junction of strata of such widely different lithological character and age, will probably be liable to constant disturbances by earthquakes more or less severe, which will take the same course as those which upheaved the long parallel north and south ridges. In the same vicinity that tertiary rocks occur Devonian rocks crop out, greatly disturbed and crushed with faults and dislocations, caused by dikes of eruptive rocks, which constantly obtrude through them. The Nandewar Range terminates about 30 miles north-west from Narrabri, when it throws out numerous spurs in every direction. The above evidence of disturbance, together with the numerous conical shaped hills which stud the country, indicate the whole country to have been liable for ages to volcanic action and earthquakes.

I have, &c.,
FREDK. B. GIPPS, C.E.

REPORT OF THE SECRETARY ON THE "CONSERVATION OF WATER IN VICTORIA."

To the President of the Commission.

Sir,

Sydney, 5 May, 1885.

I have the honor to report that, pursuant to your direction and to the invitation of the President of the Royal Commission on Water Supply for the Colony of Victoria, I accompanied the members of that body on their recent visit to the northern districts of that colony. They expressed much regret that you were unable to be with them, and they were pleased to extend to me a very cordial welcome. I had an opportunity of seeing several important works which Water Trusts in Victoria have constructed; and, as I was privileged to attend the meetings which the Commission held in the different townships for the taking of evidence, I had a favourable opportunity of learning the views of the principal residents in the several localities visited. I am indebted to the Secretary of the Victorian Royal Commission (Mr. Stuart Murray, C.E.), and to the Acting Secretary of the Department of Water Supply (Mr. C. H. Langtree), for their prompt and obliging compliance with applications I had occasion to make to them for official information.

The average annual rainfall of Victoria for the last twenty years has not exceeded 25½ inches; but in Victoria, as in New South Wales, the rainfall is very unequal in its distribution,—in some districts exceeding 50 inches, in others being less than 10. The lightest rainfall occurs in the northern districts, and over an area of nearly one-half of the Colony the rainfall of late years has been less than 15 inches, and over a considerable portion of it less than 10. The physical conditions of this area in other respects also very much resemble those of the level country in New South Wales which falls from the western slopes of the Main Dividing Range to the Murray and the Darling.

The Victorian Land Act of 1869, which provided for an extension of the area which could be taken up by free selection, and which gave other facilities for the acquisition of land from the Crown which had not before existed, coupled with the heavy rainfall of 1870 and 1875, appear to be the principal causes which led to the occupation of the northern and north-eastern districts by an agricultural population. The floods of 1870 and 1875 produced a luxuriant growth of herbage and abundant crops in the succeeding seasons, but the continuance of dry seasons from 1878 to the present time has changed the prosperous conditions of settlement in those districts, and the people have had to wage a severe struggle for bare existence. Some have had to succumb under the pressure of successive droughts, and nearly all have been reduced to the direst straits to obtain water for their stock and for ordinary domestic purposes. In some of the localities which I visited the farmers have had to drive their stock 15 and 20 miles to water, and it was no uncommon thing for the few muddy sources of supply to be besieged as late as 3 o'clock in the morning by farmers who had come long distances and had to wait their turn for many hours. In other places the inhabitants were almost wholly dependent on the water trains which the Government despatched from Sandhurst for the relief of their most pressing necessities.

Severe

Severe privations such as these quickened the perceptions of the people as to the need of permanent water supply. While the country was under pastoral occupation a large amount of capital was expended in making provision for the storage of water, and as population thickened the Shire Councils devoted a very large part of their revenues to a similar purpose. Anything which could be done in this way, however, was felt to be desultory and inadequate to the requirements of the case. Schemes of general application were felt to be indispensable, and Messrs. Gordon and Black were called upon by the Government to report as to what could be done at a reasonable expense to obtain a supply of water to the northern plains—in the first place for domestic purposes and for the use of stock, and in the next for irrigation. They pushed forward their inquiries with all practicable speed, and in the years 1880 and 1881 they were in a position to advise the Government as to what was best to be done. They arrived at the conclusion that the yearly discharge of the rivers flowing northwards into the Murray, combined with the local rainfall, would be far more than was sufficient to meet the requirements of the settlers for stock and domestic purposes, if the winter rains were stored by a system of local works and made available for distribution during the dry period of the year, and at the same time such works could be made to form an integral part of any system of irrigation which might be found practicable, having regard to the capacity of storage and the cost of distribution. The general results of their proposals were thus summarized by them in their last report to the Minister:—

Having now completed our report on the first part of the inquiry with which we were charged, we have arranged in a tabular form the information contained in the reports and the results of the approximate estimates.

It will be seen that the total area proposed to be supplied with water for stock and domestic use under the different schemes (excluding Huntly, No. X, which is a minor work) is about 8,560 square miles, or nearly 5½ million acres, and that the population settled on this area, as nearly as we have been able to ascertain it, with the kind assistance of the Government Statist, is 54,493. This population varies in density from 2·75 to 8·1 per square mile, the average being 6·8. The estimated cost of the proposed works, exclusive of the purchase of land, varies from £18 2s. to £55 4s. 9d. in the different schemes, the average being £29 16s. 10d. per square mile of country, and the annual cost of interest and management from ½d. to 1½d., the average being under ¾d. per acre. Assuming the average numbers of a household to be four and a half, the annual cost per household will vary from 18s. 3d. (in the Wimmera) to £2 17s. 4d. (in the Gunbower scheme), the average being £1 6s. 2d. Assuming that an acre of land will yield 12 bushels of wheat, or support one sheep, and that the annual net profit per acre is respectively 12s. and 10s., or an average of 11s., as statistics seem to show, then this average annual cost will be equal to nearly the annual value of 2¼ acres; and as each household has on an average 434 acres, the annual cost would, on these data, amount to the yield of about half an acre in every hundred acres.

Most of the schemes propounded have been taken in hand by local bodies, and some of them are far advanced to completion. I purpose briefly referring in detail to the more important schemes, because, as it appears to me, they contain features of great value to New South Wales. Before I do so, however, it is desirable that I should invite your attention to some of the principal provisions of the law of Victoria on the conservation and supply of water, which has given scope and protection to the great works upon which energetic and self-reliant communities in Victoria were not slow to enter when with quick intelligence they perceived, from Messrs. Gordon and Black's reports, the lines upon which they could safely proceed. In the present condition of our laws, or rather the want of law applicable to our circumstances, and the total absence of local governing bodies, it is not conceivable how any schemes for the conservation and distribution of water over large areas of country can be initiated or carried out, or, if undertaken, how they can be protected and maintained; and if I am correct in this view, it seems to me that the provisions of the Victorian Statutes applicable to country which is almost identical in formation and level with the larger part of New South Wales must have deep interest to us. The Victorian Statutes bearing upon the subject are named in the margin. Copies have been obtained.

44 Vic. No. 688
45 Vic. No. 716
47 Vic. No. 778.
48 Vic. No. 829.

The Act under which the present Water Trusts were called into existence was brought forward in the Parliament of Victoria by the Hon. Charles Young, then Minister for Water Supply, and he still takes a very lively and intelligent interest in the question. Victoria has for many years enjoyed the advantages of local self-government; and, of its total area (87,884 square miles), 83,211 square miles are under the control of local municipal bodies, designated in one class of cases as cities, towns, and boroughs, and in the other as shires. The system has many advantages as compared with that under which roads, bridges, and other public improvements are devised and executed by central authorities and paid for directly from the general revenue. It is obvious that ratepayers, knowing that they must provide a large part of the cost of any work for the improvement of their district, if not indeed, in many cases, the whole of it, are careful to enter upon such works only as are of public utility; and—having an immediate interest in the efficient and economical construction of the works—the ratepayers may be regarded in the light of a body of unpaid inspectors, whose constant vigilance is calculated to exercise a check upon extravagance and to create a healthy public opinion inimical to jobbery, while at the same time it tends to ensure an equitable distribution of the funds for shire improvements. In all probability there are cases in which the action of Shire Councils gives rise to complaints of partiality, pretty much as in municipalities of more restricted character in New South Wales. An alderman is sometimes popularly supposed to provide for improvements against his own door; but it by no means follows that such complaints are well founded; and even if they were, they are an evil small in comparison with the dilatoriness and expensiveness of what is known as centralization. The annual endowment by Government to the local governing bodies in Victoria is £310,000, but their total revenues amounted in the year 1883–4 to £1,086,502.

Mr. Young, in framing his Bill (45 Vic. 716) "for the Conservation and Distribution of Water throughout Victoria," took advantage of the organization which he found in healthy operation under the Local Government Act, and he sought to induce the Shires of different districts to co-operate in undertaking the duty of providing for their united requirements. The Water Trusts which were thereby brought into existence were constituted on the principle of Shire Councils, with only such modifications as seemed necessary to meet the new and larger functions they were called upon to exercise. The principle of local taxation for local benefits by works carried out under local supervision runs through all the statutes bearing on water conservation. The fact, however, that the Water Trusts would have entrusted to them the expenditure of Government loans, in some cases amounting to nearly £100,000, was probably the reason why it was determined that one Commissioner on each Trust should be appointed and removable by the Government, while the others were elected from among their own number by the members of the Shire Councils brought into co-operation. Section 2 empowers the Council of one or more municipal districts, singly or acting together, to prepare plans and descriptions of such waterworks as they desire for their districts; and if these are favourably reported on by professional men employed by the Minister, the Governor in Council may approve of or modify them in such manner as, upon further investigation, and

after

after the interests supposed to be in conflict with the scheme of the promoters have been expressed, may be judged expedient. The approval of the works and the constitution of the Trust is legally effected by an Order in Council, which must state—

(*a*) The amount of money which the Governor in Council will grant as a loan for the purpose of carrying out the same and paying the cost and expense of the plans and application for the same, and also the rate of interest which will be charged for such loan, such rate being at least one-half per centum more than the rate payable by the Government on the public loan out of which such loan may be granted;
(*b*) Shall proclaim the limits of the lands—whether within or without the municipal districts of the Council or Councils applying for the proposed waterworks—within which such Trust shall have authority to be called a Waterworks District;
(*c*) Shall state what are the principal works proposed to be constructed; and
(*d*) Shall contain such provisions (not inconsistent with this Act) as, according to the nature of the application and the facts and circumstances of each case, the Governor in Council shall think fit.

As a matter of fact, the plans which the Water Trusts have been formed to carry out are in the main those which were prepared at the instance of the Government, by Messrs. Gordon and Black. The Government, while no doubt they rendered a very substantial service to the districts interested by procuring the plans, are in no way responsible for them: they treat them as the plans of the parties applying for the Trust. The examination to which they subject them is to satisfy themselves as to the stability of the projects upon which they are asked to lend money, and they cannot be supposed to accept anything in the nature of a partnership liability. If the plans and estimates upon which a loan was procured were subsequently found wholly fallacious, and if it should happen that a Trust had squandered the loan upon works which turned out to be worthless, the Trust would not be able to evade their responsibility for the repayment of the loan, on the ground that the Government had approved of the plans. The Local Government Act of Victoria makes provision for the examination of municipal surveyors and engineers and the issue of certificates of competency. I am informed that the examining Board are very stringent in their requirements; and it is very probable therefore that the Shire Councils of Victoria have at their command an amount of highly skilled professional assistance which but for this circumstance would not be available. The relation of the Government to the Trusts is that of mortgagee and mortgagor. There are several sections in the Acts which provide for the supervision of the principal works—one which forbids the acceptance of a tender for the principal works until the terms of contract have been approved by the Governor in Council; another which enables the Government to require the Trust to dismiss their Engineer; another which provides that, if the Minister so requires, the municipal works shall be carried out under the supervision of an officer appointed by the Government, the certificate of which officer may be made necessary before any portion of the cost of the works becomes chargeable against the loan. Another section provides for the annual audit of the accounts of the Trust by a Government Auditor, all this being in addition to the direct representation which the Government have upon the Trust. The constitution of a Trust is provided for in section 18 (No. 716) as follows:—

Each Waterworks Trust shall consist of Commissioners to be elected from time to time by the Council of each of the municipal districts which will, in the opinion of the Governor in Council, be directly benefited by the proposed waterworks, and which shall be specified in the Order in Council approving the construction of such waterworks or in any subsequent Order, and of one other Commissioner who shall be appointed by the Governor in Council; and the number of Commissioners to be elected by each Council, not exceeding two, shall be determined by the Governor in Council.

Every such Commissioner so elected or appointed the Governor in Council may remove from office, but no elected Commissioner shall be removed from office except on the application of the Council by which he was elected.

The scrutiny of the plans, &c., by an independent authority at the instance of Government, and the provisions made for Governmental interference at subsequent stages, were no doubt primarily intended for the protection of the interests of the Colony which provides the loan; and, if the scrutiny be sound and thorough, it must incidentally be of even greater benefit to the district more immediately concerned. From statements which I have heard in different quarters, I am led to think that there is very great danger lest these provisions—however excellent they may be theoretically—should be allowed to fall into disuse, or that the supervision for which they provide should become perfunctory and valueless. I am not aware that any defect so serious has been disclosed in the working of the Acts; but it should be remembered that they have been in existence for only a very short time; and the limited experience gained is by no means conclusive against the inference which I draw from the fact that the Government have not in their service any officer whom they can hold responsible for the advice upon which they act in the approval of plans and the constitution of Water Trusts. The Government are in a position analogous to that in which our own Government would be placed if, in the various cases they have to litigate, they had no Crown Solicitor or Attorney-General to advise them, but had to depend upon the casual services of the legal profession. It is possible—at least so I have been informed, on what I take to be trustworthy authority—for an engineer to devise a plan of waterworks upon which a district proposes to obtain a Government loan, to be called in by the Government to advise them, and he may also be afterwards engaged by the Shire to carry out the works: that is to say, at different periods of the negotiation he can act for the Trust and the Government—for the mortgagor and the mortgagee. The principle of self-government is one of such inestimable value, and the sacrifice which Shire Councillors make of their time and personal comfort to enable them to render voluntary service to the general public is so great, that Governments may be expected to deal with such bodies as Water Trusts in a generous, confiding spirit; but inasmuch as the futures of a "dry" district will depend upon the stability and success of the waterworks constructed, to say nothing of the ability of the ratepayers to repay the loan to the general public, it does seem of first importance that the examination of the schemes submittted for Government approval shall be of the most searching character, and be undertaken by the best engineers in the Government Service. While the works are under construction, also, there should be a periodical inspection by competent officers, whose responsibilities should be solely to the Government. A very small staff would suffice for examining and inspecting purposes. The business would be likely to be better done, and on principles uniform in their application, as compared with the diversity which might be expected from the employment of a large number of non-official experts, paid by fees. A small staff would probably enable the Government to dispense with the provision for special representation in the membership of the Trust. While it might be taken to imply a doubt as to the capacity of the representative constituents of the Trust, the nominee element would not, in most country places, give any better security to Government than that which they would obtain by means of their

their Engineers and Auditors. It may be feared that appointments of this character might be sought after by persons who covet distinction in particular localities, and that the Government would find insuperable difficulty in discovering those best qualified to act.

As to the general powers of the Trusts, they are so varied and important that I prefer to quote the definition contained in the Act itself (section 38 of 45 Vic. No. 716), rather than to attempt any generalization of my own. It reads thus :—

For the purposes of this Act any Waterworks Trust by its officers or servants may subject to the provisions and restrictions herein contained and in accordance with plans approved by the Governor in Council as aforesaid exercise any of the following powers (that is to say) :—

It may enter upon any lands described in the plans and take the levels of the same and set out such parts thereof as it thinks necessary and dig and break up the soil of such lands or trench the same and remove or use all earth stones trees or other things dug or gotten out of the same.

It may enter upon take possession of and appropriate such land as shall be necessary for the construction or improvement of the works or for securing or improving the water to be supplied or the quality or purity thereof.

It may purchase or lease any existing waterworks and erect or construct all necessary waterwheels hydraulic engines and pumping or any other machinery.

It may from time to time sink wells or shafts and make maintain alter or discontinue reservoirs waterworks cisterns tanks aqueducts drains cuts sluices pipes culverts engines and other works and erect buildings upon the lands and streams authorized to be taken by or vested in it.

It may from time to time divert water from any lake lagoon swamp marsh river creek or watercourse to the extent specified in the authorized plan and descriptions of the waterworks.

It may from time to time divert or alter as well temporarily as permanently any part of the course of any rivers creeks or watercourses roads streets or ways in order the more conveniently to carry out any of the powers conferred on the Trusts.

It may construct weirs and dams in any river creek or watercourse.

It may cut drains and deliver water into or take water from and embank widen or deepen any river creek watercourse lake lagoon swamp or marsh.

It may at any time enter upon any lands roads or streets for the purpose of repairing or altering any watercourses and other works under the control of the Trust or in any way connected with such works.

The Water Trusts and local municipal bodies have powers similar to those reserved to the Government of this Colony under which they may enter upon lands to obtain timber and materials for road-making, but they wisely abstain from the exercise of them unless necessity arises in very exceptional cases. As a general rule all work is done by contract, and the contractor is left to his own resources in providing materials, quite as much so as a builder in providing bricks. Water Trusts, however, are compelled to enter upon and make watercourses through private property, and the law provides for compensation to the owner in the form of "easement" privileges over lands required for channels and other works, "such lands not being the site or curtilage of any house or garden, yard, court, plantation, planted walk, avenue, or nursery for trees." The compensation to be paid for the easement may be either as a gross sum or a yearly rent, as agreed upon by the parties or as may be determined under the Lands Compensation Statute. The question of compensation is one which ought to be well considered in any legislation on the subject, so as to protect individuals from oppression on the one hand and the general public from extortion on the other. The bulk of the channels will be for subsidiary distribution, not more than two yards wide. None that I saw were fenced in, but provision was made by substantial bridges for stock to cross from one part of a paddock to another, and suitable slopes are also made at which the stock can drink. The right of "easement" includes the channel and the "spoil," which is thrown a yard or two away on the lower side, and soon forms a neat grassy ledge along the line of the drains. Provision is also made on the lower side at regular intervals, to the extent of 300 feet per mile, for the escape of storm-waters in the event of the conduits being filled. These channels already number many hundred miles in length ; and owners who are disposed to put a fancy valuation upon their property will try to drive hard bargains. The "easement" right over the bulk of the property which I saw had been settled at £3 an acre, but there were those who were holding out for £10. It is extremely questionable whether in nine cases out of ten any compensation ought to be given for carrying a running stream of water through what would otherwise be waterless country—the increased value given to the land being greater than any loss of pasturage. In ordinary cases compensation may form an important item in the cost of works; and I am disposed to suggest that no compensation ought to be given to any man who cannot show that he has, by the expenditure of his own money in water supply, taken all necessary precautions to keep his stock alive. The works of the Trusts are exempted from municipal taxation.

The financial aspect of the question is one to which, doubtless, you will attach importance. The tanks and wells constructed by the Government of New South Wales have been chiefly meant to facilitate the travelling stock, and in a few instances they have also been available for the supply of small townships. The expenditure (£210,000) as a whole, however, may be regarded very much in the light of a subsidy to the pastoral interest, and as being purely eleemosynary ; for while the revenue derived as rent for the leasing of the watering-places amounts to £400 per annum, the yearly cost of supervision, as distinct from maintenance, amounts to nearly £5,000. Victoria being well supplied with railways, all the stock from long distances for Melbourne are trucked. It will have been inferred, from what I have already written, that the principle upon which Parliament has proceeded in Victoria is, that each district shall pay for its own improvement—water conservation being no exception to the rule. It is true that, in addition to the £400,000 loan raised for the purpose of being lent to the Water Trusts, the Legislature has appropriated £100,000 as a free grant. Of this sum £91,000 has been allotted, but the rule which governs its distribution is based upon the readiness of the inhabitants to tax themselves, as shown by the magnitude of the works they undertake. The particulars of the disbursement of the loan and of the grant will be found in the return (*Appendix A*) which the Acting Secretary of the Water Supply Department has been good enough to prepare for me. The £100,000 was granted as an encouragement to the inhabitants of particular districts to assume the heavy responsibilities which it was seen that any large scheme of water supply must involve ; but, unlike the endowment to the municipal bodies, it is a final and not an annual subsidy.

The law empowers any Trust to which the Government have granted a loan for the construction of waterworks to levy upon all lands and tenements situate within the district supplied "for all or any of the purposes of

(*a*) Paying interest on such loan ;

(*b*) Maintaining such waterworks in an efficient state ; or

(*c*) Extending the waterworks as the Governor in Council may authorize." (Sec. 53, No. 716.)

The

The late Act (47 Vic. No. 778, sec. 97) provides that the rate shall not be levied until notice has been given in the Government Gazette that the district, or part of the district as the case may be, is supplied with water under the provisions of the Act. The municipal valuation is to be taken as the basis of assessment (sec. 57, No. 716), and no rate shall exceed 10 per cent. per annum on the annual valuation of the property (sec. 54, No. 716). The rates may be recovered summarily before any two Justices; and, in the case of any property in a water supply district being unoccupied, and the rates accruing thereon being unpaid for a period of five years, the Trust may take possession of it and hold it as against any person interested, and may from time to time grant leases of the property (sec. 61, No. 716).

The interest which the Government charge the Water Trust is one-half per cent. higher than that at which they negotiate the loan, which—making allowance for the cost of floating the loan, exchange, and the time before interest becomes payable by the Trusts—is practically the price which the Government themselves pay for the use of the money. The last loan was raised at 4 per cent.—a much lower rate than the Trusts could expect to obtain if they borrowed the money direct. The Act 47 Vic. No. 778 provides that the aggregate amount which can be borrowed by a Trust shall not at any time exceed 70 per cent. of the value of the land within the area of the Trust (sec. 30); and if a Trust borrows money on the credit of the area which the Trust is not legally bound to pay, then all the Commissioners of the Trust who have consented to the borrowing are made jointly and severally liable to pay the amount (sec. 57, No. 778). The proviso to section 91 of the same Act sets an important limit to the borrowing powers of the Trust, with a view to protect the ratepayers from exorbitant taxation. It is in these words:—

> Provided that the amount of any such additional loan granted under the provisions of this Act to any Waterworks Trust shall be such that the sum of the yearly interest payable thereon and of the yearly interest payable on any other loan granted by the Governor in Council to such Waterworks Trust shall not exceed the amount which can be raised in any year by a rate of one shilling and sixpence in the pound upon the ratable property within the waterworks district of such Waterworks Trust.

The quotation which I have made from the principal Act (No. 716, sec. 53) indicates that the payment of interest is to be one of the objects to which the rates shall be applied; but there is nothing in the section to make it a first charge, or to prevent a Trust from applying £99 out of the £100 to the maintenance and extension of the works, leaving the payment of interest postponed indefinitely. Under the 51st section, it would be competent for the Board of Land and Works, when accepting the mortgage which the Trusts execute for the repayment of their loans, to make such a contract in regard to the disposal of the rates as the Board may deem advisable. The Amending Act of 1883 (47 Vic. No. 778) contains explicit provisions as to the payment of interest and principal. Thus, for example, section 46 enacts that every Trust shall from time to time make and levy such rates as are sufficient to pay the interest due upon any loan obtained by the Trust under the Act, and to provide for the necessary annual payments for the sinking fund of such loan, and also for all current expenses incurred by the Trust in the control and management of the area over which their powers extend. The sinking fund mentioned in this section is a very important supplement to the legislation of 1881. The extent and operation of it are set forth in the three following sections (115, 116, 117, of No. 778).

> 115. When any Waterworks or Irrigation Trust has obtained a loan under the provisions of this or the Principal Act, a sinking fund shall be formed to liquidate the same in the manner following:—
>
> Such Waterworks or Irrigation Trust shall after the levying of its first rate cause a sum being such percentage of the principal sum of such loan as may be agreed upon between such Trust and the Governor in Council not being at any time less than one pound ten shillings per centum of such principal sum to be in every year after the date of the granting of such loan and until the complete liquidation thereof or until the Commissioners of Audit or any two of them by writing under their hands certify that the amount of the sinking fund formed hereunder is sufficient to secure the liquidation of such loan invested in the purchase of Victorian Government stock which stock shall be placed in the stock ledgers in the names of the Treasurer of Victoria and of such Waterworks Trust as aforesaid to an account entitled as of such loan. Provided that in all cases in which Trusts cannot secure Government stock at par the Trust shall pay into the account of the Treasurer of Victoria and such Trust the money percentage hereinbefore directed to be invested in Government stock and all such moneys shall carry interest not being at any time more than four pounds per centum per annum and such interest shall be placed to the credit of the sinking fund in the same way as provided for interest accruing on Government stock.
>
> 116. All interest accruing due on any stock or moneys for the time being standing to the credit of any account forming any sinking fund shall be invested in the purchase of Victorian Government stock or moneys which shall be placed to the credit of the same account.
>
> 117. As soon as conveniently may be after the amount of any sinking fund shall have increased to such sum as shall be sufficient to secure the liquidation of the loan in respect of which such sinking fund was formed the Victorian Government stock placed to the credit of the account entitled as of that loan shall be sold out and the proceeds thereof shall be applied in the first place to the redemption of such loan and thereafter to such purposes as the Waterworks or Irrigation Trust which invested the same directs.

There is one other provision in the law of Victoria bearing upon this part of the subject to which I must draw your attention. I refer to the 4th section of the Act of 1884 (48 Vic. No. 829), which provides that the Governor in Council may, if in his opinion there be sufficient reason therefor, notwithstanding the provisions of the Acts of 1881 and 1883, or of anything contained in any mortgage made under the authority of these Acts, "direct that interest on any moneys secured by any such mortgage shall be charged from a day not more than two years subsequent to the day in that behalf specified in such mortgage." I am not aware of the reason which led to this amendment of the law; but considering the magnitude of the works to be constructed—that experience in the construction of such works in Australia is as yet very limited—that there are often great fluctuations in the supply of labour, and occasionally great vicissitudes in the amount of the rainfall—it will probably be acknowledged that there must have been strong grounds to recommend such a modification of the original contracts. Whether it is advisable to give to the Executive authority power to postpone the day of payment in one district and to refuse the like concession to another appears to be a question of expediency; and the assumption that a Government will exhibit partiality in the exercise of the discretion vested in them may not be more creditable to those who make it than to those assailed by it. In the absence of some such flexible provision as this, the alternative of a rigid insistence upon punctual payment might entail great hardship.

In the contingency of ratepayers or Councils failing to elect Commissioners to the Trust, the Governor in Council has power to constitute the body by appointing them (sec. 21, No. 716); and should a Trust fail to meet their financial obligations to the Government, the law empowers the Board of Land and Works (which acts for the Government in its relations to the Trusts) to take possession of the works and to levy the rates. The sections bearing upon this point are 52 of No. 716, and 46 of No. 778.

The

The question naturally arises as to the disposition of the people to pay interest on the loans. It should be borne in mind that the Trusts are of recent formation, and that in only two or three of them have the works been completed sufficiently long to admit of a rate being struck. I am informed that the Wimmera Trust, whose expenditure has exceeded £95,000, has struck a rate, and that other two Trusts whose works are on the point of completion are about to do so. It would probably be somewhat remarkable if the people did not regard the Government as a lenient creditor; and in different localities through which I have passed I have heard views expressed which appeared to me to savour of repudiation; but when the idea has been nakedly put to a witness in so many words, repudiation itself has been disclaimed. In one case where a witness was avowing views such as I have expressed, and condemning the levying of a rate, the audience in the Court-house instantly and with much warmth expressed their strong dissent. It must be extremely difficult for a visitor passing through a community to know precisely what weight attaches to the opinions of persons whom he meets in the briefest possible way; and if I had had longer opportunities for gaining information, I should still greatly distrust my ability to form a correct judgment. If the question was one which merely concerned the honesty of our neighbours, I should feel myself chargeable with presumption in referring to it; but, because I think it not improbable that the Government of New South Wales may be led to act on lines similar to those on which Victoria has proceeded, I feel bound to suggest your consideration of the subject purely as an abstract question. Just now, when the residents of the northern areas of Victoria are still painfully sensible of the sufferings and loss entailed upon them by five or six years' drought, they readily acknowledge the immense benefits which a permanent supply of water will confer on them; but after the lapse of a cycle of wet years, during which their crops might be destroyed by superabundant moisture and some of their waterworks swept away by floods, they might be less disinclined to listen to those who make large bids for popularity by counselling repudiation than they are at present. Dropping the question of honesty, I will not asperse the intelligence of the majority of the ratepayers by supposing that they would not be quick to perceive that a policy of repudiation would be more disastrous in retarding permanent settlement than the effects of the most desolating drought; but it does occur to me that the provision made by the law of 1883 for the repayment every year of a portion of the debt is one wholly in the interests of good government and sound morality. If, unfortunately, it should ever happen that one Trust should be led to try and shuffle out of its obligations, all the other Trusts who had steadily paid their interest and contributions to the sinking fund would form a strong make-weight with the rest of the community in strengthening the hands of any Minister whose duty it would be to insist upon payments due to the State by debtors whose suffrages he might have to seek.

Works of the magnitude of some of those which I have seen are calculated to evoke the liveliest admiration for the communities who have had the courage to undertake them and the energy and skill to push them on to such rapid completion, more particularly when it is obvious that the pressure of taxation must be great. It requires but little foresight, however, to perceive that present self-denial in the intelligent pursuit of their own immediate welfare must be followed by the most beneficent and splendid results to the Colony as a whole. The arid plains of northern Victoria are without doubt destined to become well watered, and much of them as fruitful as a garden. As the railways of Belgium have paid for themselves and become a source of great wealth to its people, vivifying production and giving value to the smallest articles before not worth the cost of carriage, so it may be expected that the Water and Irrigation Trusts of Victoria, having extinguished their debts by the annual payment of one and a half per cent., will become most valuable properties to the districts which have had the enterprise to construct them, and coming generations will enter upon a goodly heritage.

A feature of Victorian legislation upon this subject which strikes me as very admirable is the adaptability of its provisions to any area, say a combination of municipal districts, a single shire, a riding (which is a division of a shire), or a town, so that none are excluded from the benefits of Government help to united effort to obtain water supply, and none are included in the area of taxation whom that supply does not in one form or other benefit. (Sections 67, 79, 80, 94 of 47 Vic. No. 778.) The constitution of the several kinds of Trusts are the same in principle, and there are provisions under which individuals other than ratepayers may combine to acquire the right to conserve and distribute water, but their powers are more restricted than those conferred upon representative bodies. Waterworks districts may also be provided, and differential rates levied according to the extent of the advantage conferred. The law appears to be designed to confer substantial equity upon all—however varied the physical condition of the country embraced in the Trust—however abundant or scarce the natural supply of water in the different localities may be. I say substantial equity, because I suppose absolute equality is a thing unattainable in dealing with so many interests as are involved in any large tract of country. The man fortunate enough to own land whose configuration readily admits of the storage of water, and provident enough to construct the dams or tanks necessary to supply his wants, may object to pay taxes for works designed to benefit the majority who are less fortunate or less thrifty, pretty much in the same way as many residents in the western suburbs of Sydney, having provided themselves with abundant storage for water, might object to pay rates for the Nepean supply when it shall be brought through their boroughs on its course to Sydney. Such cases may have the appearance of hardship if the certain tendency of water supply to increase the general value of property be ignored.

The Trusts can, if they choose, arrange with the municipal bodies to collect their rates for them, but the presumption is that in most cases this dual form of local government will entail the employment of two staffs—an engineer and secretary for water purposes, a surveyor and clerk for road purposes. If there be any value in the suggestion which I have made in a previous paragraph, that special representation of the Government on the Trust might be dispensed with by a thorough examination of plans in the first instance and periodical inspection during the construction of the principal works, it might be found desirable by the Government of this Colony, in any proposed legislation on the subject of local government, to relegate the business of conserving water to them, and thus obviate duplicating the machinery of government by the creation of special Trusts. In that view of the case, it would probably be found expedient and quite practicable in the level country to determine the boundaries of municipal districts by the lines of their natural drainage areas. I assume that on the western plains the conservation and distribution of water is of paramount importance. The country being destitute of road-making material must depend upon railways, which are not regarded as local works, and as the traffic chiefly occurs in the dry time of the year the surface of the soil is sufficiently hard to bear traction.

The

The necessity for schemes of water conservation is no doubt common to all the Colonies of Australia; but, as it appears to me, there are special reasons which make the need more urgent in New South Wales than in Victoria. In the latter Colony frontages to creeks and rivers, a mile wide on either side, are reserved by the Government, so that whatever water may be found in the natural channels is accessible to the general public quite as much as to the lessee. In New South Wales these frontages and the natural water-holes have to a very great extent been alienated to private individuals, with the consequence that the lands adjacent thereto must almost of necessity pass by lease or otherwise into the hands of the pastoralist who has acquired a monopoly of the water. I presume it cannot be expected that the Government will advance money to private individuals, or permit them to intercept the flow of water in creeks and rivers; and that therefore any schemes for the conservation of water will have to be carried out by municipal bodies. Inasmuch, however, as the Crown is still the owner of immense areas of land, care should be taken, in the examination of any scheme submitted for their approval, to see that it was so designed to benefit the largest possible area, and that the whole of an available supply of water should not be monopolized by a comparatively few persons. It cannot be expected that municipal bodies would take water through unoccupied Crown Lands from which they could expect to derive no revenue; but their schemes ought to be so devised that they should be capable of commanding such areas if the natural features of the country permitted of that being done. The effect of such schemes must be to break up any existing monopolies of water, by the multiplication to the extent of many hundreds (I will even hope thousands) of miles of water frontage, and that the value of the public estate will be correspondingly increased thereby. In this view of the matter, Government will be fully compensated for such moderate grants as it may be in their power to make by way of supplement to their loans to local bodies; but I suggest that it would not be expedient to allow district municipal bodies to levy a water-rate upon *unoccupied* Crown Lands, for it is conceivable that cases might occur in which such bodies might so use their powers as to throw the burden of taxation from their own shoulders on to those of the general public. In all probability, where water is caused to flow through unoccupied land, occupation will almost immediately follow, and the taxable area will be thereby increased. The rating powers of Water Trusts in Victoria are, as I have stated, based on the municipal assessment; and if Crown Lands in private occupation are rated by any municipality, a Water Works Trust has also the power to levy rates.

It seems to be a characteristic of all the rivers flowing through the level districts to form banks higher than most of the country which they drain; and as in Victoria so also in New South Wales, there are numerous effluent creeks which draw off the flood-waters from the main streams. Inspection of the works carried out in Victoria will demonstrate the soundness of the views which, if I mistake not, you have long since formed that, by the construction of weirs at suitable points across the main streams, much of the flood-water which is now lost in the soil or which flows on to the sea might be thrown back into these effluent creeks, such as the Yanko, Colombo, and the Billabong, so that for a comparatively small outlay for head works in improving and defining the channels, hundreds of miles of natural storage might in flood years be utilized.

"Riparian rights" are, I believe, held to be an insuperable obstacle to water conservation in many districts, in the present state of the law. May I suggest for your consideration that the vesting of the control of watercourses in the hands of Trusts or District Municipal Councillors, elected by the owners of property whose interests are concerned, would be a fairly satisfactory solution of the difficulty in New South Wales, as it appears to me to have been in Victoria. I assume that here as there the Government would exercise the right of defining boundaries after the fullest publicity had been given to all proceedings and a careful scrutiny of the projects submitted for their approval. If it were proposed to vest the power of determining boundaries and granting charters in the larger authority of Parliament, I should fear that, in the absence of any machinery by which conflicting interests could be reconciled, the expense, delay, and difficulty of obtaining special Acts of Parliament would be so great as to amount to a prohibition to the adoption of large schemes for water conservation. It is by no means improbable, although I heard only one complaint, which was afterwards shown to be grounded on wrong information, that the residents of one locality included in the area of a Water Trust do not receive the same amount of benefit as do others; but it is necessary that I should point out that the works of the Trusts were constructed with a view to equalize the benefits of water conservation as widely as possible. Weirs which impound water at the heads of the streams are provided with compensation sluices through which a certain regulated quantity of water is allowed to flow to the people living lower down the stream. These, in the present development of water conservation, cannot have the same abundant supply as those living above the weir; yet if it were not for the weir they would have no supply at all—they would be left to the full enjoyment of their "riparian rights," that is to say, the privilege of contemplating an empty creek, the dryness of whose bed would absorb a large proportion of even a very copious rainfall. It seems to be only a question of time when, by the multiplication of weirs, everybody will be almost equally fortunate.

Another point in the construction of weirs in Victoria ought not to escape attention; and that is the great length of their wings. The soil of the plains is of so fine a texture that it may be said to almost dissolve under the action of water; and a very slight obstruction has often turned the course of what in flood-time is a large river. A weir which would merely extend from bank to bank would be swept away, or it would divert the flow of the river into some new channel. This danger appears to be fully recognized and successfully combated by making the crest of the weir of such a width and elevation as will permit of the even flow upon the aprons below of any flood discharges which cannot be impounded, and by carrying out the wings of the structure to whatever distance may be necessary to annihilate the scour. The designs for the weir which it is proposed to construct across the Goulburn shows a total length of 1,663 feet. Everything depends upon the stability of these structures; and no care which can be exercised appears to have been omitted in the construction of those which the Commissioners examined. The cost of them, however, does not appear to be larger than the resources of the district can meet—a result chiefly attributable to local control.

The distributing channels often intersect the public roads, and form watering-places for stock on each side of the bridge which carries the roadway over the middle of them. The channels at these points are pitched with blue-stone cubes. As there is no stone in the soil, the excavation of these channels is very cheaply made by means of horse ploughs and scoops. The work is mostly done by farmers living in the district. The price paid for the excavation of the smaller drains and depositing the soil a yard or two

away

away from the edge was 7d. and 7½d. per cubic yard. At the Waranga basin, where one side of the lake is being enclosed by a bank, on the top of which a water conduit is to be made, the cost of doing the following work was only 1s. per cubic yard of stuff in the bank:—Ploughing the surface upon which the bank was to be built, excavating soil for bank and carting it a distance of 2 chains, rolling the clay every 4 inches, so as to consolidate and practically make it into a puddled wall. The length of this bank, which is far advanced in construction, is two miles and a half, width across the top 25 feet, side slopes 2 to 1, and average height 12 feet. The price of 1s. a cube yard also includes the excavation of the conduit which will be formed in the top of the bank, and the proper disposal of the spoil. Here also horse-scoops and ploughs were the only excavating machinery employed.*

I see from Mr. Hayter's Victorian Year Book that there are forty-three towns and three shires supplied with water, inclusive of Melbourne and its suburbs, whose population, numbering about 300,000 souls, have an abundant supply at high pressure. There are several other towns which have completed their works since that return was compiled (1883–4), and it is not brought down to a date sufficiently late to include all the Trust Works to which this memorandum has almost exclusive reference. It may not be out of place, however, to mention that the storage capacity of the reservoirs included in Mr. Hayter's return is stated as being 13,202,483,932 gallons, and the cost of the works, actual or estimated, as being £3,877,485. As it may not be deemed to be within the scope of your inquiries to institute any comparison between what has been done in this direction in Victoria with what has been projected here, I purpose to abstain from writing out much of the information placed at my disposal, although I may be permitted a passing allusion to what is known as the Coliban scheme, which, though financially among the least remunerative, has nevertheless been productive of immense advantages in other respects. The water impounded in the reservoir at Malmsbury flows for a distance of 100 miles to Sandhurst, supplying several small towns on the way; and by its agency Sandhurst, which was a place perfectly hideous in its desolation, probably without a parallel in its bad pre-eminence, has become one of the most attractive and healthful towns in Victoria. It has a fine sheet of water for boating, its streets are adorned by avenues of lofty trees, whose leafy beauty is the pride of its citizens, if not indeed of the people of Victoria. This city of 30,000 souls is indebted to its water supply for an incalculable amount of comfort and prosperity, and in large measure for its continued existence. The most instructive feature in regard to town supplies seems to me to belong to those towns which have provided for their own requirements by means of loans advanced to them under the "urban" sections of the Water Conservation Acts. I may mention Echuca (population, 4,800) and Kerang (population, 400) as specimens of several others which offer a fine example to a large number of towns in New South Wales, which, having rivers flowing at their feet, could easily erect the pumping machinery and water towers necessary to supply the inhabitants by a system of reticulation; and as an example of what may be done by towns farther removed from flowing water, I may mention Kyneton (population 3,300), which, at a cost of £25,000, including the reticulation, brings its supply through pipes from storage reservoirs at a distance of 9 miles, and which, by a 1s. rate, pays both interest and sinking funds. Here, as I believe is the case generally, the water rate covers the domestic supply; but all supplies to manufactories, brewers, livery stables, and gardens, are paid for by meter.

The desire to obtain water sufficient for irrigation is very strong in the northern districts of Victoria; indeed I think I should be justified in saying that the people are becoming clamorous on the subject, so satisfied are they that wet cultivation can be carried on with results far more profitable than dry. The subject was pressed upon the attention of the Commissioners in every township and by several witnesses. This is a point upon which I have taken rather full notes, but on further reflection it seems inexpedient that I should trouble you with many details. The advantages of irrigation have been demonstrated in many countries; and it may suffice to say that the experience which is being gained in Victoria is no exception to the general rule. As showing the extent to which it is being practised where water sufficient can be obtained, I may mention that one gentleman near Echuca has pumping appliances for the irrigation of 2,000 acres, another at Gunbower for an area of 10,000 acres, and a farmer at Kerang, who said that he irrigated successfully for thirteen years, described a voluntary association of twenty-one farmers who by combining their labour managed to bring water for a distance of 13 miles, and to irrigate 3,000 acres of land. In every case the witnesses expressed themselves as highly satisfied with the results when water sufficient was obtainable; and many witnesses expressed the pleasure they would feel in paying a rate of 10s. per acre for water with which to irrigate their crops. While I was at Kerang, meetings of the "Irrigation Leagues of Victoria" were being held at the Shire Hall. The Rev. E. C. DeGaris, the President of the Central League, has been good enough to supply me with the following information respecting the Associations:—

About two years ago the agitation for water supply began to take the form of Irrigation Leagues. One was formed at Kerang, another at Durham Ox, another at Echuca, others at Rochester, Kyabram, Pyramid, Macoona, Mysia (Korong Shire). Eventually these local Leagues were united in an organization called the Central Irrigation League. This body has no particular place of meeting, and has held sessions in Sandhurst, Melbourne, Echuca, Rochester, and Kerang.

At the meeting at which you were present the other night nearly all the delegates travelled long distances: one came 300 miles, several 150, and the average distance travelled was about 70 to 90 miles each delegate, excluding of course the few who were local residents. The country embraced by the Leagues is very wide, including chiefly plains bounded by the Murray, the Dividing Range, and the Avoca River. In Wimmera the agitation is only now beginning, and the delegate from that territory, present the other night, was the first sent to our League meetings. Besides the country indicated, Bacchus Marsh and portions of Gippsland are also discussing various schemes.

There is no doubt about the earnestness of the people of the plains on the subject now, and every month furnishes new evidence of the growth of public opinion.

Much of our level country resembles that of the northern plains of Victoria, with the exception that it contains larger areas of very rich soil; but the land is owned in large blocks, and the circumstances of the population are not similar. There is room to doubt whether the rural population of Victoria for many years to come will be dense enough to utilize all the water known to be available for irrigation; but in New South Wales the population is more sparse, and those who cultivate the soil are not grouped together in communities as in Victoria. The industry of the country is almost wholly pastoral, though probably the time has come when pastoralists are prepared to irrigate largely for fodder crops as a sort of

* Since the remarks in the text were written Mr. Deakin has returned from America, and by the courtesy of the Honorable Charles Young I am able to lay before you descriptions and sketches of the buck scraper and ditching plough. The former implement may be used for excavating channels with slopes of not more than 4 to 1, and is especially suited for sand and loamy soils, in which situations it is superior to the scoop, removing such soil with a lead of 50 feet for 3d. per cubic yard.

of insurance against drought. The examples of irrigation, carried on with such remarkable profits in California, with which the Press has lately made the country familiar, relate almost wholly to fruit-growing near railways, giving quick access to a protected market of about 60,000,000 souls, and are such as we can scarcely hope to emulate here; but it is very gratifying to find that, as far as experience obtained in Australia itself has gone, it is almost uniformly satisfactory.

The amendment of the Victorian Water Conservation Act, made in 1883 (47 Vic. No. 778) enlarged the scope of the Water Trusts so as to include irrigation. The schemes of Messrs. Gordon and Black, while primarily designed for stock and domestic purposes, also embraced provision for irrigation to the extent to which the water was available and the physical formation of the country suitable. Now that the works of the Echuca and Waranga Shires Trust are nearly completed, there is reason to expect that irrigation will soon become part of the farming of the district. The pumps which will lift the water from the Goulburn are of a capacity to supply water enough (beyond what will be needed for stock and domestic use) for the irrigation of 6,000 acres, so that there is here a good opportunity of testing the profitableness of irrigation on a small scale before the Shires commit themselves to the great undertaking of constructing a weir across the Goulburn, which would supply water by gravitation. The site of the proposed weir is at Murchison. The drainage area of the Goulburn above that point is about 4,000 square miles, much of the country having an exceptionally heavy rainfall, and the river being also fed by the melting of the snow on the Great Dividing Range. The readings of the gauge placed on the Goulburn at Murchison for the last three years shows, according to Messrs. Gordon and Black, that the minimum supply available for winter irrigation is 134,000 cube feet per minute, and they estimate that the irrigable area commanded by the scheme is 610,000 acres, one-third of which could be under wet cultivation at any one time. The lowest discharge of the river in summer has been ascertained to be 28,000 cube feet per minute, which it is computed would be sufficient to irrigate 30,000 acres: and when to this is added the flood-water which it is proposed to store in the Waranga Basin (3,600,000,000 cube feet, after making allowance for loss from evaporation), the total area which may be irrigated in summer would be 62,000 acres. In their report upon irrigation, Messrs. Gordon and Black point out population "must be considered as the gradually obtained result of irrigation, and also the indispensable condition of its continuance." They are of opinion that at least eighty-five persons to the square mile, or one to 7½ acres, would be required to carry on a mixed system of farming on the northern plains of Victoria, where one-third the area would be irrigated and two-thirds under dry crops. On this basis the Goulburn scheme would require a population of about 80,000, or about ten times the present population of the locality, to utilize the water available. The following paragraphs embody their reasoning on this part of the subject:—

17. We find from a return appended to this Report, for which we are indebted to the Government Statist, that, in the agricultural districts comprised in our water supply schemes previously reported on, the population averages 8·3 per square mile. The area *occupied* is 523 acres per square mile, and 58·67 acres per head of population; and the area *cultivated*, 86 acres per square mile, or nearly 10 acres per head of population. According to the proportion ruling in North Italy, the area of fully irrigated land that could be cultivated per head of the population would be 3½ acres, but the difference between irrigated and dry crops would probably be less where agricultural machinery is more largely employed, and for the present we assume that 5 acres of fully irrigated land could be cultivated per head of the population. A simple calculation will show that, with the present population of these districts, supposing one-third of the present cultivated area to be irrigated for root crops, beans, lucerne, &c., only 75 per cent. of the land would be cultivated, *i.e.*:—

50 acres of dry cultivation, at 10 acres per head	5 persons.
25 acres of irrigated land, at 5 acres per head	5 „
75 acres cultivated by	10 „

That is to say, 25 per cent. of the land now cultivated would go out of cultivation.

Conversely, in order that only the present proportion of cultivation to occupied land—about one-sixth—may be irrigated to the extent of one-third, the population required will be 13·3, or an increase of 33·3 per cent.

33·3 acres of irrigation, at 5 acres per head	6·66
66·6 „ dry cultivation, at 10 acres per head	6·66
	13·3

18. In the same way it can be shown that, to completely irrigate the ordinary proportion—one-third—of these plains, and at the same time to dry crop the remainder, a population of at least 85 to the square mile would be required, or, if dry crops were entirely given up, and two-thirds of the land used for grazing, about half that number, *i.e.*, an increase of about 500 per cent. on the present population. From these figures it is evident that, even with an abundant supply of water, the extent of irrigation proper that could be carried on by the present population of the Northern Plains would be very limited.

19. For the second kind of irrigation, viz., occasional watering or flooding, after the first labour of preparing the land and forming the distributing channels, the labour required would not be so great, probably an additional 25 per cent. would suffice. Assuming this to be a fair estimate, and that it were desired and possible to obtain a sufficient supply of water to give an occasional watering to the whole of the area now cultivated (about one-eighth of the total area, by the official statistics), an addition of 25 per cent. to the present population would be required, or the amount of cultivation would have to be decreased by 20 per cent.

Water for the irrigation of a limited area will be obtainable from the northern lakes, fed by the Gunbower scheme, and elsewhere; but a great deal of information respecting river discharges, and the extent to which water can be stored in elevated positions at the heads of creeks, will have to be collected before the extent to which irrigation is practicable can be ascertained. The only river which has been gauged for a sufficient time to give useful data is the Goulburn. I append a list of localities where gauges have been or are being placed. (*Appendix* B.)

Witnesses examined at Echuca and in other localities volunteered opinions in favour of weirs across the Murray, so as to divert its waters into depressions on elevated land, whence it could be drawn off by gravitation for irrigation. The time may come when the Colonies interested in the waters of the Murray will be rich enough to weir (and it may be lock) as well as bridge that stream; but speculation on the subject at present is premature and of little importance. Some concern appears to have been expressed in the Legislature of Victoria lest New South Wales should divert snow-waters from their present flow into the Murrumbidgee; but this must have been in forgetfulness of the fact that one of the principal schemes sanctioned by the Government of Victoria depends in a large measure upon the waters of the Murray being drawn off by a cutting into Gunbower Creek, and that others are almost wholly dependent upon the impounding of the water of rivers which flow into the Murray.

The

The first of the schemes visited by the Commissioners is that known as the Gunbower. It embraces an area of 690 square miles, and has been undertaken by the Swan Hill Trust, who have obtained a loan from the Government of £31,600 and a Parliamentary grant of £9,111. Their works may be said to begin at a point on the Murray, 16 miles below Echuca, where the outflow of the flood-water into the Gunbower Creek has been facilitated by a channel 10 feet wide at the bottom, with slopes of 1½ to 1. The water from the Gunbower Creek is admitted by a similar cutting into Taylor's Creek, flowing thence into the Kow Swamp, which covers an area of 16,000 acres, and which it is proposed to fill to an average depth of from 12 to 14 feet. By a weir at the outlet the storage could be still further increased. From this lake the water is to flow along the Box Creek, from which it will be taken by the Macorna Channel into Tragoowell Swamp and the Loddon River. The total length of this line of conduits is 40 miles. Bagot's Creek, 3½ miles, and the Pyramid Creek branch of 30 miles brings up the total length to 73½ miles. The channels along Deep Creek, Gunbower Creek, and Barr Creek extend for a distance of 55 miles; from the weir across the Loddon at Kerang the channels to feed a series of lakes lying to the north-west extend for 12 miles; and from the Leaghur dam on the Loddon to Lake Leaghur, and northwards by Wandella Creek to Lake Meering, Little Lake, Lake Don, Wandella Lake, Pelican Lake, and Lake Elizabeth, the course is 28 miles. In all, this scheme provides for the conveyance of water for a distance of 168 miles, and the conversion of a large number of lakes and swamps into important reservoirs, from several of which water may be available for irrigation. The surface inclination north-westerly from Mitramo to Kerang, 37 miles, is 1 foot to the mile; and from Kerang to Swan Hill, 33 miles, it is 0·734 per mile. One of the principal works in this scheme is the weir across the Loddon, below the junction of Pyramid Creek, near Kerang, which has been completed at a cost of £5,211. It will have the effect of diverting a large body of flood-water along the Sheepwash Creek to Reedy Lake, Lake Charm, and other natural basins to the west of the river. I am indebted to Mr. H. C. Kempson, C.E., the Engineer to the Trust, for the following particulars showing its construction:—

	ft.	in.
Total length of weir, including wings	512	0
Length of east wing	136	0
„ west wing	176	0
„ crest, including notch	200	0
„ notch	32	0
Breadth of weir	12	0
„ cushions (aprons)	12	0
„ cushions, front of sluices	20	0
Height of weir at notch	9	6
Depth of piles in ground	12 to 18	0
„ sheet piles	8 to 15	0
Slopes of face	Vertical.	
„ aprons	Horizontal.	

Sluices (four in number) each 4 feet by 3 feet in clear construction.

Two rows main piles 12 feet apart, with distance pieces and braces internally; also tie-rods at 16 feet intervals; double wailings and sheet piles, both up and down stream; six cross-walls or shields of sheet-piling; wings; single rows of main piles with double wailings and sheet-piles, the interspace filled with gravel and clay, puddle-rammed.

Sluices– Top, bottom, and sides of 3-inch planks, dowelled, and lined with roofing felt, and 1-inch planking fixed diagonally; doors, two thicknesses of red-pine with roofing felt between, covered with 4-lb. lead outside, worked by 2-inch square-threaded lifting-screws and box-keys extending well above highest flood-level, from special platform

The next series of works visited by the Commissioners were those of the united Shires of Echuca and Waranga. The most concise description which I can give of these works will be in the language of Mr. Walter Scott Murray, C.E., Engineer to the Trust, whose evidence before the Royal Commission I had an opportunity of taking down in shorthand. He said:—

The principal works authorized and completed, or in process of construction, consist of the main channel, the length of which, from the pumping site on the Goulburn, a mile and a half above the township of Murchison, to the Cornella Creek, is about 85½ miles. The works at the pumping site are in course of construction, and consist of a pumping shaft, depth 46 feet, lined with brick, from which to the river there is a tunnel 6 feet by 4, lined with timber and puddled with clay. The entrance from the river is closed by a sluice-gate protected by timber wings. The top of the brick shaft is finished with concrete and levelled for the engine-beds. The discharge-pipe from the pumps delivers the water into a brick receiving bay, where it passes into the receiving channel by regulating brick weirs. The engines are of 270-horse power, and the pumps (Robertson's patent) will discharge 38 cubic feet of water per second, or 20,000,000 gallons in twenty-four hours. The machinery cost about £5,000, and the tunnel and shaft £1,500. Pumping operations will be commenced on the 1st June, 1885. From the discharging bay at the pumping site for a distance of 3 miles the fall of the channel is 6 inches to the mile, the bed width 8 feet 3 inches, and the depth of water 2 feet 9 inches. For the next 5½ miles the fall is 9 inches to the mile, and the bed width 6 feet 6 inches. At this point the north-eastern channel takes off, and follows approximately a course parallel with the Goulburn. The capacity of the main channel up to the point of offtake is 20,000,000 gallons a day; and from the offtake to the Cornella Creek it is 15,000,000; thence to Lake Cooper it is 12,000,000 gallons; thence to Cornelia Creek it is 10,000,000 gallons. The fall of the channel from the offtake of the north-eastern channel to the Waranga Basin Crossing is 9 inches per mile, bed width 4 feet 6 inches, and depth of water 2 feet 9 inches. From the Waranga Basin Channel there is a regular fall of 6 inches per mile, bed width 4 feet 9 inches, depth of water 3 feet. From the Cornella Creek to the Cornelia Creek the bed width is 4 feet 6 inches, and depth of water 3 feet. Throughout the whole of the main channel the side slopes are 1 to 1, except from the Cornella Creek to Lake Cooper, where the slopes are flattened to 1½ to 1. At the crossing of the Waranga Basin the channel is embanked. The other principal works are timber weirs across the Wanalta Creek, and two across Cornelia Creek. The north-eastern channel is 48 miles in length from the offtake at the main channel to the point where it joins the drainage channel. The branch No. 1 shown upon the plan is about 4 miles in length, and also joins the drainage depression; branch No. 2 is about 18 miles in length, and it also joins the drainage depression. The channel is partly excavated, partly embanked. There are regulating sluices every 3 or 4 miles, and bridges across public roads and private property. In a length of 70 miles of channel only 24 miles pass through private property—the rest are taken along the roads. The capacity of the channel at the offtake is 15,000,000 gallons, diminishing to 5,000,000 gallons in the parish of Koyuga. The capacity of the branches is four and five million gallons each. The fall of the channels averages 12 inches per mile; in some places it is not more than 8 inches, in others it is as steep as 2 feet. The Koyuga drainage channel is 33 miles long. The other channels either cross the lie of the country or follow the highest ridge, while the drainage channel carries the flood-waters into the natural depressions. We supply water when it is wanted, and drain the country when there is too much. Two other channels shown on the plan, one for drainage and the other for supply, the latter having a capacity of from five to two million gallons. Three tanks are in process of construction, and three or four months hence we propose to construct ten or twelve more to give supplies at particular points, so that people and stock can obtain water without damaging the channels. The capacity of the tanks is 200,000 gallons; they are capable of being filled from the channels, and they will be fenced round, to prevent injury and pollution by stock. Floods' patent lifts will be used to raise the water from the tanks to the iron troughs to be placed alongside. The designs for the Goulburn weir have been sent in to the Water Supply Department, but not yet dealt with. The

object

object of this weir is to supply the whole of the channels by gravitation instead of pumping. It would take several years to construct the weir. There are several small channels to make, and the Waranga basin has to be filled. Water will, in June next, be brought within 2 or 3 miles of every property in the district. The channels of the high level drains command the whole of the country, and they are designed to be enlarged at small cost, so as to serve for irrigation. The present pumping supply will be sufficient to irrigate 6,000 acres at one spot or in different localities as desired. The total area of the district is 880 square miles, and the area of the Waranga basin, which it is proposed to fill with flood-water, is 11½ square miles. The drinking approaches to the channels, where they run through private property, are made with slopes of 4 to 1, and occur at quarter of a mile intervals. It is estimated that the cost of the Goulburn weir, including compensation for land, will be about £60,000.

The operation of the Wimmera United Waterworks Trust affords another remarkable instance of the way in which a perfectly arid country has become well watered, by the judicious construction of weirs across its watercourses, which were practically dry creeks, for "in summer they retain water only at a few places." These weirs, owing to the level nature of the country, have impounded immense sheets of water which otherwise would have run to waste, and by the cutting of channels, the district, embracing an area of some 2,000 square miles, has been reticulated with water to its remotest parts. Water so diverted has also been stored in tanks and natural depressions, and a supply ample for all requirements short of irrigation has been obtained. The schemes of water conservation in this district were also outlined by Messrs. Gordon and Black, and they have been carried to a most successful issue by the Trust. The Trust has expended upwards of £95,000. The works represented by it are so numerous that I shall not attempt to particularize them, but, fortunately, by the courtesy of Mr. A. B. Clemes, the Secretary to the Trust, I am in a position to hand you a full description of the works, with a map showing the outlines of the scheme. You will, no doubt, observe that although the Wimmera was essentially a dry district, having no water in its creeks in summer, so great has been the storage that, in one case, water discharging at the rate of 90 cube feet per second is being carried to the Coorong Swamp—a distance of 80 miles from the point of diversion. A special feature in the scheme is, that a plateau of 200 square miles, 50 feet above the bed of the river storage, is being supplied with water by means of steam-engine and pumps, which raise the water at the rate of 600 gallons per minute, and it is conveyed thence through 6,500 feet of 9-in. cast-iron piping to the reservoir.

I append a return of the various Water Trusts formed under the Water Conservation Acts (*Appendix* C) which will no doubt be of interest.

Reviewing what has been done under the Water Conservation Acts of Victoria, I may be permitted, in conclusion, to suggest for your consideration the propriety of inviting the Government to follow a similiar policy here, with such modifications as your knowledge of the different circumstances of the Colony may lead you to deem expedient. This policy I may briefly recapitulate as follows :—

1. That a survey of the principal drainage areas be obtained with all practicable speed from engineers competent to advise the Government as to the best means of storing and distributing water within boundaries to be proclaimed by the Government.
2. That legislation be proposed, making provision for—
   (*a*) The incorporation of municipal districts, and conferring on bodies elected by the ratepayers, of power to enable them to devise and execute works for the conservation and distribution of water in the districts they represent.
   (*b*) Empowering Government to raise loans for the construction of works for water supply, and to lend the money to municipal bodies upon the security of their rates, mortgage being taken for the payment of interest and repayment of loan within a specified period; the plans and estimates of the works being in the first place subject to the approval of the Government, and the construction of the same being subject to periodical inspection by their officers.

I have, &c.,
CHARLES ROBINSON,
Secretary.

REPORT ON THE BARWON RIVER, AND THE TARRION AND CATO CREEKS.

To the Secretary of the Commission,—

Sir, Brewarrina, 19 May, 1885.

I have the honor to report that, in accordance with your instructions of the 9th ultimo, I have made inquiry regarding the evidence which can be obtained at Brewarrina on the subject of water conservation. I have every reason to anticipate that the witnesses who will give evidence here will furnish much information of a valuable character.

By actual levelling I have found that from still water above to still water below the rapids at Brewarrina there is a fall of 10 ft. 8 in. At the time when these levels were taken, viz., the 5th inst., the reduced levels above and below the rapids were 353·65 and 342·98 respectively. As the volume of the water in the river increases, the influence of the rapids extends to a greater distance, and in consequence the apparent fall diminishes, till in times of high floods the river surface assumes a uniform slope, and the only indication of the existence of the rocky bar is that furnished by the increased velocity in its vicinity.

Assuming that an effective fall of 9 feet is available, the power which can be derived from it is about 1-horse power for every cubic foot per second of discharge. There is unfortunately no place near Brewarrina which is suitable for gauging the discharge. On the upstream side of the rapids a very deep pool of almost still water extends for many miles. The depth of this pool just above the rapids is said to be no less than 30 feet. I went up the river to a distance of about 6 miles, and failed to find a bed at 10 feet depth throughout that distance. With the experience I have obtained regarding the discharge of the river near Walgett, and after again inspecting the flow at Brewarrina, I have come to the conclusion that, although there is no apparent flow at present into the river between Brewarrina and Walgett, the discharge of the river between these places is increased by percolation. The discharge at Brewarrina is certainly greater than at Walgett. This I attribute partly to the increase by percolation, and

and partly to the fact that the rocky bar at the former place acts as a dam, in stopping not only the water within the river channel but that flowing beneath it. The discharge at Walgett is only about 15 cubic feet per second, while that at Brewarrina, so far as I can judge, is not less than 25 to 30 cubic feet per second. Assuming that the latter discharge is correct, there is a loss of 30-horse power, and this, too, close to the township of Brewarrina, and in a place where water is greatly wanted. Supposing that so much as 30-horse power would be obtainable for the purpose of pumping water from the river, and allowing for a loss of 25 per cent. in the working of the necessary machinery, the quantity which could be raised to the average level of the land near Brewarrina would be about three and a half million gallons per day. This quantity of water would irrigate from 1,300 to 1,400 acres of land under the ordinary system; or, if used under the asbestine system for the irrigation of fruit trees, it would be sufficient for nearly 30,000 acres.

In connection with the question of putting weirs in the Barwon, I may point out that the rocky bar at Brewarrina gives great encouragement to such a project. The fact that a splendid sheet of deep water can exist permanently in the Barwon is a most important point to have established, as without such an instance to the contrary it would naturally be assumed that the immediate effects of a permanent dam of any kind in the river would be to cause the deposit of a large quantity of silt.

At a distance of about 4 miles from Brewarrina the Cato Creek flows in a course approximately parallel to that of the Barwon. The creek is in reality a branch of the Barwon, but instead of flowing into that river direct it joins the Bokhara. The length of the Cato Creek is estimated at 60 miles. At the head its cross section, as measured roughly by me, is 1,500 square feet, and opposite Brewarrina about 2,000 square feet; while towards the Bokhara its capacity increases considerably. Assuming the dimensions opposite Brewarrina as an average of the whole, the total capacity is 633,600,000 cubic feet. As it would probably not be practicable to utilize more than one-third of this, it may fairly be stated that in the Cato Creek there is available storage for 210 millions of cubic feet of water, or (say) 1,300 million gallons. Near the punt at Brewarrina, and on the banks of the Barwon, there is a large boulder which, it is said, must be under water before the flood-water will pass down the Cato. The reduced level of the top of the boulder is 354·59 feet, and it is about 11 feet 7 inches above the present water level on the downstream side of the rapids. At the inlet of the Cato Creek, the height of its bed above the present water level is nearly 15 feet, but the effect of a rise at any particular point cannot be estimated without more levels, and in both cases the figures regarding the floods required to fill the Cato should only be taken as approximate. It is, however, quite clear that a large supply could be stored in the Cato, and that flood-water which in ordinary seasons runs to waste could be utilized for this purpose. For the proper investigation of this question a longitudinal section of the Barwon from Brewarrina to the head of Cato Creek should be made, and special cross sections should be taken at the places where rocky bars are met with. Tarrion Creek, which is distant about 7 miles from Brewarrina, occupies a position on the south of the Barwon, corresponding to that of the Cato on the north. These creeks or ana-branches leave the river on opposite sides near the same place. From the nature of the country the Tarrion Creek appears to derive much more benefit from the surface water than the Cato does; but on the other hand, the flood in the Barwon requires to rise about 5 feet higher to cause a flow into the Tarrion than is required for flowing into the Cato. Near the place where the Brewarrina and Byrock Road crosses the Tarrion Creek is a splendid sheet of water, which, I was informed, extended for 6 miles without a break, and with a surface width of about 200 feet. At this place the Tarrion Creek is much larger than the Cato. If the dimensions of the Tarrion for 6 miles of its length can be taken as the same as at the Byrock Road crossing, the total storage capacity for that length would be at least 100,000,000 cubic feet, or (say) equal to an available capacity of 45,000,000 cubic feet. The portions of the Tarrion Creek which are adapted for water storage, though said to be much less in the aggregate than the length of the Cato, afford nevertheless a better and more permanent storage than any part of the Cato of which I have heard. On the whole I should recommend that, as a first step towards utilizing flood-water from the Barwon in the neighbourhood of Brewarrina, cross sections of the Cato and Tarrion Creeks should be taken at such intervals as would give a good approximation to their capacity, and that a longitudinal section of the Barwon should be made from Brewarrina to above the inlets of these creeks. I may mention that in the case of the Tarrion Creek there is a perceptible fall in the surface of the ground from the bank of the creek in a southerly and westerly direction, so that the conditions are favourable for the distribution of any water which could be spared for irrigation.

I have, &c.,

H. G. M'KINNEY, M.E., M.I.C.E.,
Engineer to the Commission.

REPORT ON THE MACQUARIE RIVER AND THE DISTRICT BETWEEN THE MACQUARIE AND THE BOGAN RIVERS.

To the Secretary of the Commission,— Sydney, 29 May, 1885.

The Macquarie being a fair type of that numerous class of Australian rivers which, beyond certain points in their course, gradually diminish in volume, definite information regarding the cause of this diminution is interesting and important. The importance of the question was shown by my investigation of February, in the course of which I ascertained that of 114·5 cubic feet per second which then flowed past Dubbo only 52 cubic feet per second went beyond Warren. In my inspection of the Macquarie during the past month I found that only about 20 cubic feet per second were flowing past Dubbo, and that the flow entirely ceased at about 18 miles up stream from Warren. In my report on the former experiment I showed that not more than about 9 per cent. of the discharge at Dubbo, or 16½ per cent. of the total loss, could be due to evaporation, so that at least 83⅓ per cent. of it was due to percolation and absorption. As the discharge of the river decreases, the velocity decreases in a corresponding degree, while but little change takes place in regard to the surface exposed to evaporation. The proportionate loss by evaporation therefore increases with a diminishing discharge. Taking the rate of evaporation as one-eighth of an inch in 24 hours, I estimate that while the discharge at Dubbo was 20 cubic feet per second, 7½ cubic feet per second was lost by evaporation between Dubbo and the place at which the flow ceased. The loss by evaporation was therefore about 38 per cent. of the discharge, leaving 62 per cent. to be accounted for by percolation and absorption. In the first series of experiments the loss of water between

between Dubbo and Warren, exclusive of loss by evaporation, was about 52 cubic feet per second. This is considerably less than half a cubic foot per second for every mile of the river, or about two-thirds of an inch per day over the wetted surface of the river-bed. The rate of percolation worked out in the same manner in the second case for the smaller discharges amounts to only a quarter of an inch per day over the wetted surface. These figures must only be regarded as approximate, as it would not be possible to ascertain the exact wetted area; but the result agrees with the opinion I had formed after inspection of the banks and bed of the river, that the loss arises more from lateral than from downward percolation. Such a loss as this would not be unexpected in the case of a canal following the ridge line of an alluvial tract of country; but in regard to rivers flowing in stable channels—that is, in channels following the natural drainage lines—it is natural that there should be a gain from and not a loss by percolation. In my report on the Darling, dated 19th instant, I have pointed out that on the portion of that river between Walgettand Brewarrina there is a gain by percolation, and that in the present low state of the river this gain is of considerable importance. I have ascertained beyond doubt that there is a further gain in the same manner between Brewarrina and Bourke. Percolation into the river at Bourke is at present evident, as the water in the river is about 4 feet below the level of the top of a saturated stratum. That the percolation in the case of the Macquarie is from the river arises chiefly, if not entirely, from the fact that the course of the river north of Narramine is not now a true main drainage line. While the country slopes northward with the river, it also slopes in a westerly direction towards the Bogan; and I believe it will be found that the line of greatest slope is towards the Bogan in the direction of Cannonbar, and not toward Mount Harris and the Macquarie Marshes. While the river has been depositing silt in its bed in the form of a wedge, the thick end of which is near Dubbo, another wedge having its thick end on the west bank of the river has been formed by the deposits of silt left by successive floods. This characteristic of the Macquarie affords remarkably favourable conditions for the diversion and storage of flood-water. In the district lying between the Macquarie and the Bogan there is a complete network of creeks, all or nearly all of which are well suited for the conveyance and storage of flood supplies. The first place of this description to the north of Dubbo is about 3 miles from Narramine, in a south-easterly direction. At this place is an immense lagoon about half a mile in width, and probably 30 feet deep in the centre, but which becomes shallow towards the river, from which it derives a supply in very high floods. This lagoon is at the head of the Boggy Cowal, the flood-water in which passes on to the Beleringa and Gunningbar Creeks. I had not an opportunity of following the course of the Boggy Cowal, but ascertained that there are already three dams across it.

At Buggaboo Point, about 10 miles down stream from Narramine, the river takes an abrupt turn in an easterly direction, and although the left bank at the bend is nearly 40 feet high, there is an overflow there in high flood. The flood-water passes from this place in a broad shallow depression to Buddah Lake, which is said to hold a good permanent supply. The left bank at Buggaboo Point consists of an alluvial deposit throughout, and, so far as I could ascertain, there is no favourable site for a weir in the Macquarie near that place.

At about 16 miles by road from Narramine there is a rocky rapid in the Macquarie, which bears some resemblance to the rapid in the Barwon at Brewarrina. The bed of the Macquarie at Rocky Point, as the neighbourhood of the rapid is termed, consists partly of hard conglomerate and partly of soft sandstone, intersected by bands of ironstone. This rock has a mean length of about 250 feet in the direction of the river, and the surface is rough and waterworn, but nearly level from bank to bank. The width of the bed is about 200 feet, and the height of the left bank is about 40 feet. At the time of my inspection the water in the river had a clear fall of about 2½ feet, while there was a further fall of about 1½ feet in the 60 feet on the upstream side of the vertical drop, making a total fall of about 4 feet from still water above to still water below the rapid. Notwithstanding the presence of rocks across the river-bed, Rocky Point does not on the whole afford a satisfactory site for a weir. The river here is unusually wide. The banks consist chiefly of alluvial soil, and the rock is not of uniform soundness; still the site is probably the best obtainable on that part of the river.

There are two other possible sites for weirs—one about 200 yards down stream from the Rocky Point cataract, and the other about 250 yards further down. At the former place the bed of the river is only about 100 feet wide, about 30 feet of which consists of rock, the rock also appearing in the right bank to a height of 5 feet above the bed. At the second site, below the cataract, the width of the river bed is about 120 feet, and the height of the banks from 50 to 60 feet, rock appearing in the bed at both sides of the river, and the left bank is of sound material throughout its entire height. From a distance of 200 feet above to nearly half a mile below the site of the river is almost straight. This is a point of considerable importance, and one which adds materially to the value of this site.

At a distance of about 7 miles south of Warren there are two outlets from the Macquarie. At the river bank these outlets are well defined, and bridges have been built over them at a distance of about 120 feet from the bank. The more southerly and smaller of these outlet channels is provided for by a bridge having one span of 30 feet, while the larger outlet, which is about 600 feet further down stream, has two spans of 27 feet each. The beds of these channels are, in each case, about 23 feet above the river-bed, which here consists chiefly of a yellowish clay. After leaving the river the flood-water spreads over several square miles of low lands. The head of the Bird's Nest Creek at the edge of the lowlands is in a direction almost at right angles to the direction of the river, and at a distance of about a mile and a half. This creek crosses the Nevertire and Warren Road at a distance of about 4½ miles from Warren, and flows into the Beleringra Creek. At the downstream end of the great lagoon mentioned, that is, at a distance of 5 miles from Warren and 2 from the point where the flood-water leaves the river, another creek, stated by some to be the Guningbar Creek, takes its rise, and flows past Warren, at a distance of less than half a mile from the river. By levelling from the river at Warren to this creek I found that the bed of the creek is only about 5½ feet higher than the bed of the river.

It is necessary to explain that much confusion exists regarding the names of the creeks which run from the Macquarie towards the Bogan, the same creek being known by different names at different parts of its course.

From my inspection of the Macquarie I was in a position to arrive at the following conclusions:—

(*a*) That the damming of the river at or near Warren could be done at a moderate cost, and that the result would be to throw a supply down the Guningbar and other creeks.

(*b*) That the damming of the Macquarie at or near Rocky Point would be quite practicable, and that with a dam of 20 or 25 feet in height, a supply of water could be drawn from the river in ordinary floods; but that the cost of damming this part of the river would be heavy.

(*c*) That in the Boggy Cowal, about 3 miles from Narramine, there is storage capacity for a large supply of flood-water.

Considering that the conditions for diverting and storing flood-water in the district between the Macquarie and the Bogan are exceptionally favourable, I think that, as a first step towards carrying out works with this object, the following levels should be taken:—

(*a*) A longitudinal section of the Macquarie, from Dubbo to Mount Harris, with cross sections at every 5 miles, and additional cross sections at places where the flood-water leaves the river.

(*b*) A connecting line of levels between the railway bench marks and the river at Narramine.

(*c*) A section from the river to the great lagoon at the head of the Boggy Cowal, near Narramine.

(*d*) A connecting line of levels from the river at Warren to the railway bench mark at Nevertire.

(*e*) A connecting line of levels from the river at Mount Harris to the railway bench marks at Nyngan.

The lines of level here mentioned are indispensable for carrying out of works for the conservation and supply of flood-water from the Macquarie. That such works are practicable is beyond doubt, and the levels are required in the first instance to show the position, extent, and approximate cost of the works which would be most useful.

H. G. M'KINNEY, M.E., M.I.C.E.,
Engineer to the Commission.

REPORT ON THE UPPER MURRAY VALLEY.

To the President and Members of the Commission,—

Gentlemen, Sydney, 18 June, 1885.

Object of examination. The object of my examination of the Upper Murray basin was twofold: (first) to determine if it was possible to divert a portion of the river into the valley of the Billabong Creek, and thus establish a permanent stream between the Murray and Murrumbidgee Rivers; (second) to discover if it was possible to impound any large quantity of water on the large flats near the sources of the river to account for the supply of such stream.

Geological features. In order to give some impression of the principal characteristics of the valley from Albury upwards, I shall commence my report by a brief description of its geological and physical features. The geological formation of the valley on the right bank of the river for about 50 miles above Albury is granite. This is followed by sandstone schists and clay-slates tilted at a high angle, and metamorphosed by the intrusion of trap and gneiss dykes, which strata extend about 25 miles to Ournie. From this point to Bringanbrong Station, just below the junction of the Indi and Hume branches, granite again predominates, intersected in places by belts of schistose and trap rocks. Above Bringanbrong the metamorphic strata again prevail, and as a consequence the mountain ridges assume a wilder and more precipitous aspect. About 12 miles higher up both branches of the river enter defiles through the above strata, which are almost inaccessible. The Hume heads in the granite spurs of Mount Kosciusko, whilst the Indi heads in limestone springs, from marble or mountain limestone, in which fine specimens of fossil fish have been found.

Physical features. The physical features of the valley alter perceptibly with its geological features. Where granite predominates the mountain ranges and cross ridges have a gradual slope, and often near their summit recede into table-lands, whilst the valley itself opens out into large rich flats, and the river flows over low falls, followed by long stretches of deep and almost level reaches. Where metamorphic schists and eruptive rocks prevail, the valleys of the river and its tributaries close in to narrow gorges and rocky defiles, which rise with rugged precipitous flanks into high ridges or lofty peaks, distinguishable by their sharp outline. Shortly after leaving Bowna the road up the valley crosses low spurs and ridges which enclose the valley on either side of the river. On the Victorian side the ridges rise higher, and are more rocky and precipitous. The principal timber is composed of gum, box, apple-tree, peppermint, and wattle, and patches of fir in some of the gullies. After passing Wagra, about 30 miles above Albury, the aspect of the country all round is wild and mountainous. Everywhere appear high ridges, surmounted by peaks of varied form, which, as they descend into valley, throw out numerous long spurs. The junction of every creek or tributary is marked by flats, which increase in area higher up the river at the junctions of three main feeders, the Tooma, Hume, and Indi Rivers. On the New South Wales bank of the river the Gingellic, Ournie, Greg Greg, Wellaregang, Bringanbrong, Khancoban, Indi, and Tom Grogan Flats are the most notable.

Declivity of the river. The height of the Murray at Albury is 490 feet above sea-level. Its fall for 30 miles below Albury averages 1·18 feet per mile. From Albury to Jingellic, about 100 miles up by river, it increases to 2 feet per mile; thence to Tinialdra, about 35 miles higher up, it increases to nearly 3 feet per mile, which declivity it retains to the junction of the Indi and Hume streams. It flows with a most tortuous course through the flats, especially between Tintaldra and the above junction. From this point, following the Hume, the declivity increases but slightly for 10 or 12 miles, averaging about 5 feet per mile to the top of Khancoban flats, when it enters an almost inaccessible gorge for 15 or 16 miles, then crosses the Geehi flats, after which the declivity rises rapidly by frequent rocky falls to its sources in the spurs of Kosciusko. At Geehi flats the barometer read just 1,400 feet above sea-level, giving a total fall of 910 feet between that point and Albury. Following the Indi from its junction with the Murray the declivity averages about 5 feet per mile for 15 miles, and then rises rapidly in an inaccessible rocky defile for from 20 to 30 miles, when Tom Grogan's flat is reached. Here the bed of the river changes again to falls of from 3 to 5 feet, followed by long, almost flat reaches, for a distance of about 5 miles, when it is again enclosed by the huge rocky ridges of the main range, and the declivity increases rapidly by rocky falls to its source in a gully of the Pilot Mountain, which is 5,000 feet above sea-level. At Tom Grogan's flat the barometer read 1,730 feet above sea-level, or 1,240 feet above Albury.

From

From a rough section of the river at Tindaldra I estimate its discharge there at over 1,000 cubic feet per second. A few miles above the junction of the Tooma, and about 4 miles below Mr. Findlay's house, the discharge was about 675 cubic feet per second. The volume of the Hume River, just above Khancoban Creek, by rough measurement was about 400 cubic feet per second, and at Geehi flats about 285 cubic feet per second. The discharge of the Indi at Tom Grogan's was about 300 cubic feet per second. Discharge of the river.

From Albury to the junction of the Hume and Indi, for 15 miles above that point, the Murray stream runs over a succession of low falls, followed by long deep reaches, apparently almost level, the current being so sluggish as to be hardly perceptible. Above the Khancoban and Indi Falls the divided streams run as torrents, the rocky falls being sometimes over 10 feet high, as far as Geehi and Tom Grogan Flats, when they again resume their former condition of low falls and long reaches. Above these flats they again run as torrents. The bars or falls in the river below the junction of the Indi and Hume are chiefly formed of gravel of medium size, mixed with sand; above the junction the gravel is mixed with large boulders, whilst above Geehi and Tom Grogan the river has chiefly a rocky bottom. The average width of the bed from Wagra to Tintaldra is about 160 feet, and it has an average depth at summer level of about 4 feet for such width. Its banks have an average height of 10 feet on the flats above summer level, which increases to 30 or 40 feet when the valley closes in. They generally have a deep stratum of fine river silt on top, followed by 3 feet of gravel and sand mixed. The water is clear and soft to the junction of the Tumberumba Creek, when the tailings from the gold-fields discolour it. General description of river.

The stream is generally at its lowest level in June, July, and August, when the hard frosts contract the streams in the higher regions, and the mountains and high table-lands are covered with snow. The thaw sets in about the end of August, and during the next three months, in fact up generally to the end of December, the river is in flood from the melting of the snow. After that it gradually lowers until March, when the heavy autumn rains again increase its volume for the next month or two until winter sets in.

In investigating the feasibility of diverting the Upper Murray into the Billabung Valley, three objects were especially necessary of attainment: (first) to discover a pass in the dividing range through which the river might be diverted at the lowest possible point in its valley; (second) to discover the point at which a sufficient volume of water could be diverted to cross such pass; (third) to find out if the character of the intermediate country would permit of the construction of a canal at a reasonable cost. Guided by the advice of some of the oldest residents in the district I examined the head of the Jingellic valley, where I found a low pass by which the main road between Jingellic and Germanton crossed the Divide, about 17 miles distant from each place. By barometric measurement the height of this pass was 1,670 feet. Following the ridges east for about 1½ mile I crossed another pass nearly as low as the first, and possessing the superior advantage of very steep slopes on either side, so that a tunnel about 3,000 feet long would reduce the height by nearly 160 feet. Having determined on the lowest point in the Divide, I proceeded to examine the Tooma River, which is the largest branch of the Upper Murray, to discover if it was possible to divert its stream over the pass. This stream joins the Murray River about 20 miles below the junction of the Indi and Hume branches, and is far larger in volume than either of them. It rises on the northern slopes of Mount Kosciusko, and receives all the drainage of the extensive table-lands and mountain ranges between its source and Mount Manjar, flowing fully 45 miles in a north-westerly direction to that point. On its approach to Mount Manjar it changes its course abruptly to westerly, and rushes through a narrow rocky defile with precipitous sides, and over a series of high falls, till it reaches the base of the mountain, having fallen over 2,000 feet in about 8 miles. Near this point it is joined by Pound Creek from the north, which traverses a fine flat, over 3 miles long, above the junction. The valley now begins to open out into flats bounded by high ridges on either bank, till it is joined 20 miles lower down by the main Tumberumba River, formed by the junction of the Miracle, Paddy's, Tumberumba, and Manus Creeks, when it expands into rich extensive flats on both banks of the river, which continue until it reaches the Murray, about 12 miles below. By a rough measurement of the river at the junction of Pound Creek I estimated its discharge there at 450 cubic feet per second,—the height of that point read by barometric measurement, 1,650 feet above sea-level. The discharge and height were therefore sufficient for the purpose of a canal through Gingellic Pass into the Bullandry. It was impossible without a detailed survey to fix on the actual position of the off-take for a canal, but as the river rises very fast I presume that the required elevation would be obtained 1 or 2 miles higher up than the above point. This is supposing that the canal would be 90 miles long and would have a fall of 2 feet per mile. The distance between the point of off-take and the Gingellic Pass would be about 34 miles in a direct line; but by a brief examination of the intermediate country and a rough measurement on the map I estimate the probable distance of a contour canal at 90 miles. Out of the 450 cubic feet now available at the lowest season of the year, I would suggest that 200 cubic feet per second should be diverted by a contour canal, and conducted into the Billabong Valley by the Gingellic Pass. Canal from the Tooma River to the Billabong Valley.

The sectional area of such a canal would be 75 square feet, its depth 5 feet, its fall 2 feet per mile, and its duty or discharge 200 cubic feet per second, or 108,000,000 gallons per diem. My reasons for not recommending a larger canal are (first) because of the difficult character of the intermediate country it would have to traverse; (second) because a large supply would not be immediately required and might lead to waste; (third) on account of economy of construction. Size and fall of canal.

The character of the country the proposed canal would traverse is, as may be surmised in such a mountainous region, very rough and rugged, whilst the long bounding ridges of the different divides with their numerous spurs would probably increase its length nearly threefold. The dividing ridges generally rise almost precipitously from the beds of creeks to a height of 200 or 300 feet, and then slope away more gradually. Near their base they are but scantily covered with soil; in fact at intervals they expose a wall of solid rock, but as the slope decreases the depth of the soil increases. Where granite is crossed the soil is loose and somewhat porous, but the soft granite rock below affords excellent holding-ground when slightly puddled; where the slates are crossed the soil is chiefly a good stiff impermeable clay. At first sight, and especially to an inexperienced eye, the feasibility of taking a canal across such a rough country would seem very doubtful; but having seen much greater difficulties surmounted in California than this line suggests, and having laid out and constructed different large mining ditches in Kiandra on the same mountain ranges, such a scheme appears to me practicable and at a reasonable cost. Starting from the right bank of the Tooma River, the line of canal would cross the drainage lines of Marracle, Paddy's, Tumberumba, and Mannus Creeks, and also of the Ournie and Jingellic Creeks, and would then Character of country on line of canal.

pass

pass by tunnel into the Billabung Valley, whence it might pass on through Germanton and terminate in Urana Lake, affording provision for the irrigation of the intervening rich flats. Most of the above creeks could be crossed by wrought-iron fluming on high trestles, whilst a portion of the larger streams might at intervals be diverted into the canal to account for soakage and evaporation. The cost of such a canal to Jingellic Pass, supposing the distance to be 90 miles, and including tunnel and headworks, might be roughly estimated at £200,000, and as it would traverse Government land nearly the whole distance there would be no costly rights to resume.

Duty of canal.

I estimate that a stream of 200 cubic feet per second should be capable of irrigating 80,000 acres, or that each cubic foot should supply 400 acres. On reference to other countries it appears that a flow of 1 cubic foot per second irrigates—

717	acres in	India,	supplying several waterings;
630	„ „	Spain,	„ „ „
786	„ „	California,	„ „ „
1,168	„ „	Tasmania, for hay only.	

So that my estimate cannot be considered excessive, whilst if subsoil irrigation was generally introduced, it might be safely assumed that 1 cubic foot per second would irrigate over 1,000 acres, as no surface water is exposed to evaporation.

Return of canal.

Estimating the whole cost of canal at £500,000, and that it would irrigate 80,000 acres, then at a charge of only 10s. per acre per annum it would return 6 per cent. on capital, after providing 2 per cent. for repairs and supervision.

Motive power.

In consideration that the value of every 100 feet of fall of the above stream would represent over 2,000-horse power, in a commercial aspect such a scheme must be highly profitable. It is safe to assume that, owing to the elevation of the proposed canal, it would encourage the establishment of more than one large manufacturing centre, whilst such application would in nowise prevent the water supply afterwards being equally available for irrigation.

Reservoir sites

The small declivity of the river between Albury and the junction of the Hume and Indi branches prohibits the impounding of its main stream for diversion into the Billabung Valley, but the large flats at the entrance of and extending some 10 or 12 miles up both these valleys suggest the possibility of completely controlling the river under all conditions, by impounding its whole volume and the equalizing the flow of the stream at all times, or distributing it as the different seasons may require.

Murray reservoir site.

The area of the Murray watershed above the junction is about 1,100 square miles, over which there is an average rainfall of fully 48 inches annually. Supposing one-third of the rainfall to enter the river-bed, then its whole stream would be equal to a discharge of 40,888,320,000 cubic feet, or 254,734,233,600 gallons annually. This supply impounded would permit of increasing the volume of the Murray after the junction of the Tooma River to a constant flow of about 2,000 cubic feet per second. For the purpose of such a reservoir a fine position for a dam offers in the immediate neighbourhood of Mr. Findlay's house, about 1½ mile below the junction of the above affluents. Here two long rocky spurs, somewhat above 100 feet high, approach within about 3,000 feet. An embankment across the river 95 feet high connecting them would enclose about 17,000 acres, including nearly the whole of the Bringanbrong, Khancoban, and Indi flats. At an average depth of 60 feet this area would impound 44,431,200,000 cubic feet. Large tunnels with regulating valves through the spurs on either bank of the river would provide outlets from the lake, whilst a long bend in the spur on the Victorian side would offer facilities for a by-wash. Only three Italian lakes, viz., Lago Maggiore, Como, and Di Gardi would exceed such a reservoir in area. There is abundance of excellent material for the construction of the embankment in the neighbourhood. As a large portion of the reservoir would be in Victorian territory, it would either have to be purchased from that Government, or its construction might be undertaken by the joint Colonies, which, in consideration of an equitable adjustment of water rights, would be most advisable.

Khancoban reservoir site.

In case of the Murray reservoir being considered impracticable, there are two or three other sites worthy of notice. At the entrance of the Hume Valley a dam 80 feet high would throw the river back fully 12 miles, and would flood about 7,000 acres, including the Bringanbrong and Khancoban flats. The length of the dam would be about 6,000 feet; its extremities would abut on steep spurs of metamorphic schists. This basin, with an average depth of 30 feet, would impound 57,422,500,000 gallons of water.

Geehi reservoir site.

A dam 80 feet high across the narrow rocky defile of the river at its outlet from the Geehi flats would cover at least 800 acres with water, and would impound about 8,712,000,000 gallons. The flats are enclosed by the steep walls of long lofty ridges thrown out by Mount Kosciusko. The dam would be overshot, and constructed of rock; its length at bottom would be about 150 feet, and at top 500 feet. Its extremities would abut on the hard metamorphic rocks forming the walls of the defile.

Tom Grogan's reservoir site.

The outlet from Tom Grogan's Flats offers another somewhat similar position for an overshot dam. Such a construction 80 feet high would flood 2,000 acres to an average depth of 25 feet, and would impound 13,612,500,000 gallons. The dam would abut on walls of hard metamorphic schists on either side; it would measure about 100 feet at bottom and 500 feet at top.

Recommendations.

As the result of my examination of the Upper Murray valley I beg to make the following recommendation:—(First) that a longitudinal section of the river be extended from Albury to the junction of the Hume and Indi; (second) that a line of levels be run across from the mouth of the Gingellic valley to the pass at its head, and from Wallaregang up the Tooma River to the point of offtake of the proposed canal; (third) that the line of such conduit between those points be levelled and traversed; (fourth) that the head of the Billabung Valley be examined for a site for an impounding reservoir to receive the canal supply; (fifth) that failing the discovery of any such receiving basin, Urana Lake should be examined for the same purpose; (sixth) that the continuation of the canal down the Billabung be surveyed; (seventh) that a gauge be fixed in the river at Tintaldra, and advantage be taken of Mr. Bowden's kind offer to record its readings; (eighth) that all unalienated lands on the Bringanbrong, Indi, Khancoban, Geehi, and Tom Grogan flats should at once be reserved from sale; (ninth) that the sites of the above suggested reservoirs should be surveyed; (tenth) that a Conference between certain members of this Commission and certain members of the Victorian Royal Commission on Water Supply and Conservation be invited, for the purpose of suggesting certain definite lines of legislation to the Parliaments of each Colony as to the treatment of rivers and watercourses which border or intersect the boundaries of the two Colonies.

SYNOPSIS OF THE EVIDENCE.

H. C. Russell (Second Examination).

Wells.

PAGE.

Number on Map.	Name of locality.	Depth in feet.	Supply in gallons.	Temperature, Fahrenheit.	Rise of water in well to within feet of surface	Remarks.
1	Wee Wattah Station.....	142	℔ min. 50	82°	...	Good water; five other wells on same station, depth from 134 feet to 142 feet, near mud-spring.
3	Gnalta Station	272	...	...	100	Artesian.
5	Mullyer	49	12	63	...	Four bores close to mud-spring.
	Medlow	12	℔ hour 36	...	...	Near Farina (S.A.), at 17 feet sand-drift.
	Goonery Station	122	1,000	...	...	
	Near Goonery	61	...	...	21	Abundant water.
	,, ...	69	...	...	3	Fossil bones, large teeth, at 34 feet.
	,, ...	76	65	...	...	Sunk 6 feet deeper gave 1,000 galls. per hour.
	,, ...	443	..	...	...	Tree found at 300 feet from surface.
	Bingera.....	75	..	...	...	Water rose 6 feet in 1½ hour.
	Tolarno.....	93	...	...	...	Salt water (south of Wilcannia).
	,, ...	135	...	...	...	Salt water, very fine sand-drift, deeper water fresh.
13	Dunlop Station	488	...	...	90	Strong supply of fresh water.
	,, ...	573	...	...	15	Abundant. In bore met with petrified wood, trees, and fossils. At 550 feet, 5 feet sandstone.
	Mount Browne	...	...	...	...	Inexhaustible; supplies engine and 18,000 sheep
16	Girilambone.....	155	...	...	...	Abundant fresh water, rose 22 feet 6 inches.
17	Near Forbes..	136	...	..	...	Rose 76 feet in a few minutes; white sand.
	St. Ann's	60	...	...	...	At Cooper's Creek, north of Wilcannia.
	,, ...	90	..	...	..	
	Urisino Block	430	..	...	100	Bore went through limestone rock with fossils.
	Avon Plains....	28	200	...	...	In Victoria.
	Tarkanina	1,220	..	...	...	Rose 20 feet above surface, north of Farina (S.A.); salt water at 800 feet.
23	Walgett	...	...	...	...	Salt water in fine drift sand.
,,	Sale	62	...	...	10	In Gippsland (V.)
,,	,, ...	231		...	...	Artesian, overflowing, bringing up dead leaves, &c.
26	Zaen	400	...	...	.	Wimmera District; plum-stones at 250 feet.
27	Gnalta	127	..	...	...	Rose 50 feet in the well.
	Parkes	40 to 50	...	...	...	Unlimited supply; similar wells in the neighbourhood.
	Ardennes	300	...	..	..	Wilcannia District; first class quality.
	Gilgoin	28	.	...	...	Sandy bottom; rose to surface; skeletons of large animals and fossil teeth met with.
	Collana	...	...	..	..	Artesian well, 450 miles from Adelaide.
32	Depôt Glen	55		...	..	In Albert District; unlimited supply.
	Boorara	40	...	...	...	In fine sand; brought up charcoal.
34	North of Walgett	80	...	..	...	In fine sand.
	St. Stephenson	205	.	...	...	Spring of fresh water 274 miles north of Adelaide.
	Brindigabba.....	125	...	..	43	Near Hungerford, close by at 130 feet no water; shells and lignites at 120 feet.
38	Winchelsea	488	300 to 400	...	...	In Victoria; artesian.
39	Mallee Scrub	112	..	...	...	In South Australia; the Mulga gives a supply of 2,000 gallons per hour from below loose drift.
42	Near Bourke	192	..	.	...	
,,	,, ...	61	...	...	...	Rose 40 feet in borehole.
	Sunk by contractor on Nyngan-Bourke railway line	76	...	...	...	Salt water; bore passed through quartz and hard clay.
		76	...	...	...	Salt water; bore passed through clay and sand.
		115	...	..	...	Salt water; continued to 135 feet without fresh water.
		70	...	...	...	Salt water; at 142 feet more salt water rising 50 feet.
		150	...	...	...	No water of any kind.
	Snowtown	166	200	...	...	In South Australia; rose to 16 feet above surface; good water.
	Cobar	627	℔ day 300	...	...	
52	Greenhills	90	...	...	...	On Barcoo, in several wells; water as soft as rain-water.
	On Darling River Downs	80	..	.	.	
	Narramine	...	...	...	...	Petrified myall at 180 feet.
54	Nondaro	140	...	..	..	Good water.
	Wandoola.....	159	..	.	..	Liverpool Plains; through 100 feet red soil, with layers of gravel with fossil bones and teeth.
	,, ...	60	..	...	...	Overflows for last fifteen years.
	Near Silverton	240	.	...	..	Rose 72 feet in the well.

P. B. Moore.

James Tyson, junior.

J. E. Pearce.

ROYAL COMMISSION ON CONSERVATION OF WATER, &c.

MINUTES OF EVIDENCE.

TUESDAY, 1 *JULY*, 1884.

Present:—

Mr. BARTON, M.P.,	Mr. GIPPS, C.E.,
Mr. DONKIN, J.P.,	Mr MURRAY, M.P.,
Mr. FRANKLIN, C.E.,	Mr. TOWNSEND.

R. L. MURRAY, Esq., M.P., IN THE CHAIR.

Mr. David Greig called in and examined:—

Mr. D. Greig. 1 July, 1884.

1. *Chairman.*] You are the principal in the firm of Messrs. John Fowler & Co., Leeds? Yes.
2. You are manufacturers of excavating implements suited to the purpose of water conservation? We have been making such machines, some for the Australian Colonies—for South Australia, and there has been one standing here for some time, owing to the machine not being able to comply with the Government specification, which is to be modified now. I think we have sent ten machines to South Australia. Sir Thomas Elder has four of them for himself. The Queensland Government also have two of our excavators.
3. Have you had any experience in the working of these machines in the Colonies? Very little; my chief knowledge of it is from what I gather from men who have been working them. I have worked them at home simply for the purpose of perfecting the invention. I have had an opportunity of consulting men who have returned home after working them.
4. Can you suggest any alteration in the form of dams, or any variation in the terms of existing specifications for such works, so as to admit of a more economical working of such labour-saving machinery? Yes; I think there is a great deal of unnecessary expenditure on the dams at present. The saving which according to my calculations might be effected is rendered impossible by the present specifications. In one case there has been a useless expenditure of £837.
5. *Mr. Donkin.*] Was that in this Colony? Yes. Nor do I consider the present specification right in itself for the purpose for which it is made, namely, the conservation of water. The dam, according to that specification, is too steep in the inclinations. I have been told by squatters of large experience that the sides of the tank will not stand at 1 to 1½, nor do I think the soil of the country will stand anything of the kind. Then, if the sides do not stand, the loss is much greater than the cost of making a greater slope so as to keep them permanent and neat and clean. Then, as regards our machinery, we cannot work the scoop with a slope of 1 to 1½, as it has to come up the slope of the dam to lodge the earth on the embankment.
6. *Mr. Franklin.*] With greater slopes you would get out the earth with greater facility? Yes; you want to reduce the steepness of the slopes from 1 to 1½ to 1 to 3, and that is quite as steep an inclination as will allow the embankments of any tanks to stand, especially the tanks that are open to live stock.
7. *Chairman.*] By what name is your excavator known? As "Fowler's Scoop."
8. *Mr. Donkin.*] It is used with a plough? Yes; you plough first and then use the scoop. The machine was shown in the International Exhibition in Sydney.
9. It is worked by two stationary engines, I believe? Yes, one at each end of the dam. You plough the ground to the depth of 15 inches each time it is used, and then begin to excavate. The longer the machine is acting continuously, the more work it will do for the cost. The machine here at present is in the hands of a good man, Mr. Doudney, who can tell you all about it. I have analyzed his accounts from beginning to end, and find that he did very well in taking out large quantities of stuff.
10. *Chairman.*] Have you had any experience of tank-sinking in other Colonies? No; I have sent machines to other Colonies, but it is only recently that I have heard how they succeeded. The whole business arose from the action of Mr. Peter Waite, Sir Thomas Elder's partner. I worked the machines at Leeds, and sent him four of them.
11. Can you point to any tank which has been excavated by the machine in this Colony? Yes; the tank excavated by Mr. Doudney, for Sloane & Co., on which £837 was uselessly spent in making the embankments mathematically square and finished nicely, which I think is nonsensical.
12. *Mr. Donkin.*] That is not possible to do with this machine? No, nor is it necessary.
13. *Chairman.*] Can you refer to a case of the most successful mode of using the machine? There is only one in this part of Australia. I would refer you to Sir Thomas Elder, of South Australia, or the information can be obtained by writing to Mr. Peter Waite, who manages the whole business there.
14. What number of yards do you think the machine will excavate per day in free soil? About 500 cubic yards on an average.
15. What would that cost? I have not reckoned it up, but I will send you a statement of the actual cost.* At present I do not know the expenditure by Mr. Waite; but I may say that the actual cost of taking

* NOTE (*on revision*):—About £6 per day.

Mr. D. Greig. 1 July, 1884.

taking out the earth will not exceed 6d. per yard, if the machine is kept continuously at work. When the machine is kept standing for any length of time the cost would be something more.
16. You cannot describe the machine well without a photograph? No; but I can send you a catalogue in which it is described.
17. What is the cost of the largest tank made by this machine? £1,800 or £2,000 in this country; I cannot say what Sir Thomas Elder's tanks cost.
18. Is there any shifting of the machinery required to pass the stuff on to the embankment? No, the machine passes it at once, and almost as neatly as if the work had been done by hand.
19. What is about the batter? On the outside whatever may be preferred, on the inside 1 to 3.
20. *Mr. Barton.*] What is the original cost of the machine? I cannot give that; I will let you know what it would be when landed in Sydney.*
21. Then its capacity for working is said to be 3,000 yards a week? Yes, and in proper hands that may be largely increased in summer-time, when we have long days, and the machine does not stop.
22. And the weekly expenses of the working would be about £36? I think about that amount.
23. Is there any separate power employed to take the machine from one part of the country to another, or is the machine fitted to effect the transit? No other power is required. If the Government to-day gave an order to proceed to work at a place 18 miles distant, the machine could be at work to-morrow.
24. Does that mean that it could travel 18 miles a day? On an English road we can do 30 miles; but in the Colony, where the roads are not clear of stumps, the rate would be about 3 miles an hour, with scoop, plough, waggons and baggage, and all things requisite for working the machine.
25. *Mr. Donkin.*] Take as a maximum a 50,000 yards tank, is there any difference in keeping the earth out of the way, as compared with the case of a smaller tank? Not the least.
26. Where does the earth go? At the ends and sides—all round.
27. Is it taken by the scoop? Yes, by means of three wheels centred on an axle. As the earth is deposited, the part of the machine which is nearest the ground spreads the stuff.
28. In the case of a tank of 10,000 yards, with a slope of 1 to 1½ or 1 to 3, you would have a large embankment? They do not ask for more than 10 feet in height. I have suggested the planting of a few trees on the embankment, to make it firmer.
29. In bad weather, or when there are heavy rains, much of the embankment must wash into the tank? We keep it back about 30 feet.
30. In a 50,000 yards tank, you get an immense embankment, which can be seen 3 or 4 miles away? But there is no difficulty about it, if you make the base so wide as to be capable of holding the stuff.
31. I think there has been some unnecessary expense on a dam at Nymagee, on account of the slope? Yes, it was 1 to 1½, owing to which £837 was spent on it unnecessarily.
32. For what purpose? To make it look beautiful. Where there are dams with a slope like that, it is not the custom to let stock get into them; troughs are provided to render it unnecessary.
33. *Chairman.*] You can make the base of the embankment as broad as you like, and spread the stuff as you like? Yes; if we want the embankment as small as possible at the top, with a due height and proper slopes, we take the surplus stuff to the lower end. There is scarcely any necessity for it to be brought to the corners.
34. *Mr. Donkin.*] How do you calculate the area dug out? You calculate it by measurement of the hole. We do not calculate the corners, but take a straight line, and we get the slope at the ends.
35. Have you any interest in any machine at work? No; I have a part interest in the invention, and in perfecting it, and I take an immense interest in getting the machine here to work properly.
36. That is the only one in New South Wales? Yes.
37. *Mr. Gipps.*] Some of these machines are working in South Australia? Yes, six belonging to the Government, and four are working for Messrs. Elder & Co., and one for Mr. H. B. Hughes, Adelaide.
38. Do you know the localities? No.
39. Do you know the dimensions and forms of the tanks on which the machines have been employed? No.
40. Nor the costs of the excavation? I heard that it cost 6d. per yard. I learned that from Mr. Waite's letter.
41. Do you know anything of the strata operated upon? No; it matters little what the strata may be if the steam plough will enter.
42. *Mr. Townsend.*] Do you know anything about the cost of the transit of the machine, as far as the state of the weather might affect it—in very wet weather, very dry weather, or where there is a scarcity of water? In ordinary weather there would be no difficulty; in dry weather there are means of carrying water; in wet weather there would certainly be some little difficulty in getting through bogs, which may add to the cost of movements somewhat.
43. What is the width of the tires? 2 feet 6 inches, or any width you like. The machine in the Colony is similar to that which was in the International Exhibition here. I do not think you need be afraid of moving the machines. We had one which went 500 or 600 miles, at the rate of 15 miles a day.
44. Can the power used for working the machine be used for moving it? Yes; the engines can be used for any purpose where power can be taken off by a belt.
45. *Chairman.*] Do you know what quantity of water and fuel is required for the supply of the machine? If kept fully at work, it will require about 1,400 gallons of water per day, and about 3 tons of wood.
46. In the event of getting away from water, or into constantly dry country—would not that be a great obstacle to the use of the machine? Of course; but the machine has a traction engine that holds 1,400 gallons, which could be used for obtaining supplies. Both here and in South Australia water has been brought a distance of 20 miles to the machines.
47. Have you an agent here to take orders in Sydney? Yes; Mr. Noakes.
48. Have you any machine here now? No; Mr. Bennett has a photograph which I have no doubt he will lend you.
49. *Mr. Donkin.*] In what year did you invent the machine? It is about ten years ago.
50. Was it originally intended for the purpose of excavating tanks? Yes, by Mr. Waite's wish, and we spent £10,000 on it. The patent is in my name and Mr. Waite's.
51. I think they use the plough on railway excavations now? They do. Arthur

* Note (*on revision*):—The cost of the machine, specified as follows, would be about £3165, landed in Sydney, f. o. b.:—Two 16-h.p. patent compound ploughing engines, steel drums, one 4-furrow plough, one patent excavating scoop, water-lifters, wire rope, duplicate wearing parts, &c.

Arthur Hastings Doudney called in and examined:—

A. H. Doudney. 1 July, 1884.

52. *Chairman.*] You know the excavator recently used by Messrs. Sloane & Co.? Yes; I am manager for them in its work.
53. How many machines have you had at work? Only one plant.
54. Have you been long working that? We have had it about thirteen months.
55. Have you sunk many tanks in that time? One, which is a large Government tank.
56. Of what capacity? It is 1,903 yards, and the works in connection with it bring it up to 2,000 yards. The accurate deposit would be 1,974 yards.
57. Where is that situated? At Melrose, between Condobolin and Nymagee. That is the only tank I have excavated.
58. At what expense did you sink that? Exactly 1s. 9d. per yard. That was the contract price, and that is exactly what the tank cost in excavating.
59. Have you any other experience in working that excavator? Yes, I have seen it worked, and was engaged for a time in providing tanks with the plant.
60. In this Colony? At Burrawang.
61. Can you give the name of the person who used it? Yes; Messrs. Edols & Co., at Burrawang.
62. Do you find much difficulty in travelling the plant? No, very little difficulty indeed; the chief difficulty is in getting through heavy sand—that is the only thing that troubles us.
63. The whole plant is drawn by traction engines? Three traction engines are in use. I have travelled with the machine 120 miles.
64. What average can you do per day? 12 miles in timbered country, and 20 miles in plain country. In going round the timber we have to slow down, so as to take care that everything clears the trees, and to be cautious in steering the best course, so that there is a great loss of time in that kind of country.
65. What fuel and water do you use? We burn wood, and the quantity of that and the water will depend upon the work being done.
66. What is the amount of the water and wood usually required? 1,500 gallons of water per day, and the wood is a small amount—about two dray-loads a day. When I had 5 miles to go to draw water for a few weeks I found two trips a day all that was necessary. The wood is a very small consideration.
67. What is the average extent of excavation a day? It depends entirely on the shape of the tank; we found it far better if the bank is not too steep,—then the work is 450 or 500 yards per day, or 3,000 a week; but that I think can be increased. I have been working with the first-idea scoop, but I expect that when the one coming by the "Abergeldie" arrives we shall be able to accomplish 600 yards a day.
68. Does this excavator distribute the earth where you want it placed? Yes; but not only that,—it also spreads the earth along in layers and makes the banks firmer than would be the case if a cartload was just tilted up.
69. Can you suggest any improvement on tank-making—any better method? The tank we made cost 1s. 9d. per yard, and I would willingly do the same work for 1s. 2d. per yard if the slope of the bank, instead of being 1 to 1½, had been 1 to 3, and the banks 5 feet high instead of 9 feet, which extra height is of no earthly use. With the banks reduced to 5 feet and the batter to 1 to 3, I would make the same tank for 1s. 2d. or 1s. 3d. per yard, and at that rate I could make a large profit. With the plant we had we could have made from £180 to £200 a week, which we lost in the end by taking out the corners.
70. What was the depth? 18 feet, but that does not matter in the cost; provided the slope is allowed to be a little shallower we go any depth—to 30 feet if necessary.
71. *Mr. Franklin.*] Would not such an alteration of the slopes allow a greater evaporation of water? It would, and to that extent there would be a loss if the tank was the same depth. But if you go 2 feet lower down, there would be a greater body of water than that obtained in the present specification. The loss of water by evaporation from the surface would be more than compensated by the greater body of water, owing to the 2 feet extra depth.
72. Can tanks be sunk at a greater depth than that in the present specification at less cost? With this plant it would make no difference if the depth were greater, say 27 feet.
73. Is there any reason why tanks should be kept at a maximum of 18 feet depth? No; it was the first idea, and the same specifications have existed for fifteen years. For twelve years I have known tanks to be made on exactly the same specifications, which were framed with the idea of pumping in the water from swamps with centrifugal pumps; but they carried out the specification where there were sandhills and no chance of water lodging there. Yet the same specifications are kept up, and there is the same expense for excavating; they do not alter the shape of the tanks to suit the country in which they are situated.
74. Are you aware that in designs of the tanks in Riverina this depth was established in order to avoid a loss of water through the drift which was ascertained to exist below? No, I am not aware of that.
75. But there would be no objection to going to a greater depth? No objection whatever. With this plant the drift would have to be very bad for the water to get away. In a sand-drift at 15 feet deep a shower of rain fell, of about 10 or 11 points, when the water was only 2 or 3 inches high in the tank, yet not a drop percolated through the sand-drift—there was no soakage. This can be accounted for by the heavy weight of the scoop, the wheels of which harden the ground as they pass over it. This happened in January, in hot weather, when water was more liable to soak away. I thought it remarkable, as we had been ploughing up the sandstone. The scoop weighs about 5 tons, and when loaded would give a weight of 10 tons, which weight continually running over the ground hardens the surface so that no water can escape through it.
76. *Chairman.*] Then you consider that an advantage? A great advantage, especially in drifty country.
77. *Mr. Franklin.*] At what height can the spoil be deposited on the bank conveniently? I can do it up to 12 feet, provided there is a fair run up the bank.
78. That is a matter of detail? Yes. A slope of 1 to 1½ is disadvantageous, and in our case the embankment was 15 feet high in some places.
79. Will the machinery admit of the deposit of the soil on all sides of a rectangular tank? Yes, we deliver anywhere.
80. Suppose a piece of country with a gorge in which we desire to form an excavation in one part of the area so as to throw the water back, how much work could be done by the machine daily? Of course a great deal would depend on the soil; I should say we could give a full average of 600 yards daily, working eleven hours a day. It is an advantage to have the loads coming out all one way. I have been used to take

A. H. Doudney. 1 July, 1884.

an average of six scoopfuls every ten minutes, but after we had got three-fourths of the way down I was glad to get one scoopful in each quarter of an hour; and I have been half an hour getting one scoopful.
81. You draw over the bank as you deposit each time? Yes.
82. So you consolidate each layer? Yes. We had to shift some of the spoil with drays, and we found it so hard that we had to use a pick—we could not shovel an ounce of it.
83. You removed a certain amount of the spoil by the scoop, and where did you deposit it? Outside the bank, which was 15 feet high.
84. In what time? In nine days, in terms of the specification.
85. You deposited it on the slopes in seven weeks? Yes, with three drays and from seven to nine men. In first depositing that dirt I had used the utmost care not to run the scoop over it; yet it made the material so hard that it had to be picked, as it could not be shovelled. I had to cut a flume from the silt tank into the main tank for the passage of water; the depth was 3 feet of sand and loam, in which the engines bogged. When I came away after seven months this was hardened so much that I had to get powder to blast it; this was owing to the engines having passed over it. Among my men, some of whom were navvies, it was considered a curious thing that the weight of the engines would so harden down the earth round the tank. It does away with expensive puddling.
86. *Mr. Barton.*] With regard to this particular tank, what object was there in having an embankment all round it? I could not find out, unless it was to break the action of the wind on the water, as has been stated.
87. There was no object at all to be served? No—they own that. I suggested to break the action of the wind by big stakes with wicker-work, but they would not allow me to do it.
88. What would be the best shape to sink, and the best batter so as to work your plant to advantage? The best batter would be not steeper than 1 to 3, and the shape may be that which will best suit the ground. It may be oblong, square, horse-shoe form, or circular, as some are in Riverina; it does not matter which. Sheep generally run round a tank and are likely to bog in the corners, so some tanks are made round in order to avoid corners.
89. You estimate the capability of this excavator at 3,000 yards a week? Yes, with everything in good order.
90. Then how came it to take seven months to excavate 20,000 yards? There were difficulties with the men, and I had great trouble with the specification, squaring all the corners down, making the sides of the tank like the walls of a room, and trimming the banks, which the Road Superintendent laughed at. In a short time the work of trimming these corners could not be seen.
91. What number of men does it take to work this plant? Eight men with the working manager—which place I take myself.
92. That is a total of eight men when the plant is in full swing? Nine with the manager. It would take nine men, but I work with eight, reducing the number by one by acting myself as working manager.
93. Are these men only ordinary labourers, or are they mechanics? With the exception of one they are ordinary labourers. I found it better to get ordinary bushmen than to get engine-drivers from town. It is better to have the experienced man to break in the bushmen, who are more contented with the life in the country.
94. That one then is an engineer? A. fitter.
95. I believe you took the engines and scoop from Sydney to Burrawang? From Burrawang they were brought from Mr. Edols' establishment, and I took them to Melrose, to Messrs. Harden & Co.'s station, a distance of 83 miles.
96. How long did it take you to travel those 83 miles? I was steaming five days for the 83 miles. We broke the axle against a stump, and it took two days for a blacksmith to mend it.
97. As to this tank you sank at Nymagee? It is 65 miles from Nymagee and 45 from Condobolin. It is 5 miles from Melrose homestead.
98. Did the Messrs. Edols & Co., of Burrawang, sink any tanks with this plant before you bought it? They had put down eight tanks I believe.
99. Do you know what their capacity was? They were from 7,000 yards to 15,000 yards; that is as far as my knowledge goes.
100. Do you know the depth of them? 15 feet one and 12 feet the others. I know they shifted from one tank to another 8,000 yards away within a fortnight.
101. You gave some evidence just now in reference to tanks sunk in Riverina many years ago; I think that evidence was calculated to mislead the Commission; you seem to suppose that the average depth then was 18 feet? For the Government tanks only.
102. I think you say you can sink a 30-feet tank without extra expense? They have been sunk 27 feet in South Australia without further expense, but I cannot tell what the batter was—I think 5 to 1.
103. Do I understand that you can sink 30 feet with a batter of 1 to 3 without extra expense? As the depth increases we should require a longer slope. If you go down 30 feet we should require a slope of 4½ or 5 to 1.
104. What batter would you require when 10 feet down in sinking a 30-feet tank? We should require 1 to 5 right through.
105. You start with the same batter? Yes. We might be able to do with less, but I know that the deeper we went the steepness of the batter became more inconvenient.
106. *Mr. Donkin.*] You state that at Burrawang seven or eight tanks were sunk with the machine? Yes.
107. What batter was used then? 3 to 1 always.
108. Is that for the sides and ends? Mr. Edols showed us batter of 1½ to 1 in the sides; the ends were always 3 to 1—never steeper.
109. Generally the batter is 3 to 1 all round? Yes.
110. Are the tanks for the Government fenced in? Yes.
111. As to the cost of carriage, do you know whether the engines went from Sydney to Burrawang by road? They went from Sydney to Orange by rail; thence by road to Burrawang. The difficulty then was owing to the inexperience of the men in charge and their inability to find water. The engines had not then the winding drums which they have now, so that if an engine is bogged a rope is fastened on, and, anchoring to a stump firm in the ground, the engine can help itself out of the bog.
112. What was the distance of your embankment from the edge of the tank? 30 feet.
113. What was the slope of the embankment? 1 to 1½.
114. The same as that of the tanks? Yes.
115. Was there any object in that? None that I can conceive.

A. R. Doudney. 1 July, 1884.

116. You say it took you seven weeks to remove a quantity of earth over the embankment, and that it took seven men to do the work; what was the object in doing that? They compel us to have the bank uniform—the same slope, width, and depth all round, and I had it as I considered uniform. The consequence of this requirement is that you never know when the bank is finished. They compelled me to round the embankment.
117. If this embankment is all round the tank I suppose it is 15 feet high? Only in one place.
118. How did the water get into the tank? Through the flume from the silt tank.
119. Is the tank full? No. They have very expensive woodwork, and wanted a kind of apron put in the bottom of the tank—a regular platform for the water to come on to it; whereas if they used some sheets of corrugated iron it would have the same effect.
120. Do you think the tank would ever fill? I think never except after heavy rain.
121. To what depth do you think it will fill? About 2 inches of rainfall in a heavy storm may put 2 or 3 feet in it.
122. It is never likely to be of much use—never likely to be full? No.
123. Were the tanks at Burrawang made in the same way better off? No. I think the squatters found that the surface-water was not worth bothering about—it percolates away. They looked for more from excavation, and made very nice tanks with tastefully finished corners with the plant alone.
124. The hard stuff which was put round the Government tank, the excavation of which you superintended, I suppose was put there to protect the tank from the wind? They say it is for that purpose.
125. Was this tank in level country? Yes.
126. You could see the embankments from a long distance? No, it is amongst thick pine scrub.
127. Is the soil decomposed granite? Yes.
128. Did you get any granite in sinking? No; we got cement, gravel, and sandstone, which I could plough.
129. What quantity is the scoop capable of removing at each time—I suppose the small scoop holds about a ton? The scoop we use holds 3½ cubic yards.
130. *Mr. Gipps.*] Suppose I wanted to make an embankment 30 feet high, would the scoop deposit each layer evenly over the whole surface of a base 170 feet wide? We should be in want of sufficient earth.
131. What is the height of each layer? About 8 inches.
132. A course is made of each layer? Yes; they are deposited one on the other.
133. And the weight of the machine consolidates each layer? Yes; and each layer with the others.
134. In forming an embankment you bring the machine on each layer, so as to incorporate one with the other? Yes; that is done by the four wheels. The weight passing over consolidates the ground. The Queensland Government wanted to cut through an embankment, and found it almost impossible with picks and shovels.
135. Do you think it would be possible then to raise an embankment 50 feet high? Quite possible, provided the bank was wide enough to allow the engine to go on it. The engine would be on the outside of the bank after laying the dirt; three drays would be required, and they could not get up there supposing the bank to be made the width of the engine, and to be several feet high.
136. You mentioned that water percolated through a stratum of sand: what was the character of the sand—what was its colour? It was a grey sand.
137. A free sand? Yes. I scooped it up without ploughing it. I could plough it a foot, but the scoop would take up 2 inches more.
138. What is the cost of working? Wages only, £18 10s. a week.
139. And the cost of fuel? Included in the cost of wages, about £2 a week.
140. And what is the cost of wear and tear? The firm have been allowing 10 per cent., but I find that the depreciation does not amount to more than 2½ per cent.* The engines are well built and strong.
141. That is 10 per cent. per annum? Yes. £10 a week of that would go to capital account, 10 per cent. being to that extent in excess of depreciation. There is twenty years life in the engines. They have been used longer than that in the old country.
142. *Mr. Townsend.*] Does the price you mention for wages include supplying the plant with water? Yes. We have besides the two winding engines a traction engine.
143. *Mr. Donkin.*] What is that for? For drawing wood and water.
144. The traction engine ought to be able to get through light scrub? So she does; trees would have to be 6 inches through to stop her. With one engine I travelled 84 miles in 3½ days of steaming, and carried 7 tons of loading and some passengers, and it was a very bad road between Overflow Station and Melrose, where there were many awkward creeks. The engines then were not in good order.
145. Are the tanks you have referred to on this or the other side of Melrose? On the other side. There are seven tanks between Nymagee and Condobolin.
146. Did any one take charge of the tank you excavated? There was no one who would take charge of it. We have finished it, and cannot get the money for it.
147. What was the total cost? I think we were to get £1,750. It has been measured by the road superintendent, Mr. Adams, and there may be some difference between his and my measurement.
148. What was the object in putting a tank there? I do not know. The bank is too steep for stock, and none go that way. They go by way of the Bogan now. At this place there is no feed; it is all pine scrub, and is not a used stock route to anywhere.
149. You had some rain when you were there? Yes.
150. What was the effect of it on the batter of the dam? It was all washed down. Gutters had been formed in the embankment, and when the rain came the wash from these gutters cut the earth away and carried it into the tank. Where it had been 18 feet deep in the corners it became only 15 feet deep.
151. If it had not been taken over from you, you would have had to keep it in repair? I have to do it.
152. *Mr. Franklin.*] For how long? Only until they take possession of it.
153. *Chairman.*] Are these tanks mostly in flat country? Mostly they are.
154. *Mr. Donkin.*] How long will it take to fill this tank? I do not know. No levels were taken.
155. What is the height from the top of the embankment to the bottom of the tank? 28 feet. We could have gone 30 feet.
156. *Chairman.*] If the conformation of the country would suit it and the tank was on a high level and not fully closed in it might be utilized? Yes, if that kind of country could be obtained. 157.

* NOTE (*on revision*):—I have thought this matter over, and conclude it would be safer to allow the depreciation to remain at 10 per cent. per annum. An accident to the machinery would thus be provided for.

A. H. Doudney. 1 July, 1884.

157. In the flat country the embankments would be useless? Yes.
158. *Mr. Donkin.*] Have you had a large experience among tanks? Seven years' experience of Government tanks and private tanks. I was a surveyor in the Telegraph Department, and made the subject of tanks a study for many years.
159. *Chairman.*] Which Telegraph Department? That of New South Wales. I was always constructing lines in the back country, and studied the subject of tanks with a view to becoming a contractor. That is how I came to understand them before having this plant.
160. *Mr. Donkin.*] Have you had any experience of private tanks with embankments all round them? Yes.
161. Of what depth? Up to 10 feet.
162. But only where water can be pumped in? Yes. In some cases the tank is in the shape of a horseshoe, with the dirt thrown round its closed sides.

THURSDAY, 3 *JULY*, 1884.

Present:—

MR. BARTON, M.P.,	MR. GIPPS, C.E.,
MR. DONKIN, J.P.,	MR. LYNE, M.P.,
MR. FRANKLIN, C.E.,	MR. MURRAY, M.P.

W. J. LYNE, ESQ., M.P., IN THE CHAIR.

Henry Chamberlaine Russell, B.A., Government Astronomer, called in and examined:—

H. C. Russell, B.A. 3 July, 1884.

163. *President.*] You are the Government Astronomer? Yes.
164. You have obtained and kept records of the rainfall of the Colony for a number of years? Yes, since 1870. I was appointed Government Astronomer in August, 1870, on the death of Mr. Smalley. At that time there were only five meteorological stations in the Colony. Mr. Smalley discontinued a number which had been in operation before he came to the Colony; but when I was appointed to the office which I now hold I immediately endeavoured to increase the number of stations, taking up all the old ones and establishing a number of new ones. I at first experienced a great difficulty in enlisting the sympathy of those who should have been most interested. The mere publication of the rainfall table did not attract sufficient attention—persons did not read the table; and it occurred to me that it would be well to make the record on a map. In 1878 I published the first of the rain maps, and since that date I have not had the slightest difficulty in increasing the number of contributors. There are now upwards of 400 persons contributing to the rain records. I am sorry that I did not commence this plan earlier, but I did not think of it before. Since 1879 I have been collecting records of the height of the river at Bourke, Wilcannia, Menindie, Pooncarie, and Wentworth, on the Darling; Wagga Wagga, Hay, and Balranald, on the Murrumbidgee; and Albury, Moama, and Euston, on the Murray. I have published these heights with the rain records on the rain maps. The maps have shown the river heights at these points. Mr. Moriarty kindly offered to give me the records which he had kept. I do not know when he began to keep these records, but the earliest record which I have received from him is for 1872. I will give to the Commission a list of the papers which I have received from the Department of Harbours and Rivers (*Appendix A* 1); you will then see to what year the records apply, but it will be observed that they are not consecutive. Since I appeared before the Commission last week I have made inquiries at Albury, at Dubbo, and at Bourke. The reply which I have received from Bourke is that there are no records prior to 1879, the year in which I commenced to publish them, and when of course any person could obtain and keep a copy. From Albury I received the same answer. The only records of which I can hear at Dubbo were kept during the time when the railway bridge was being erected, or during about three years. These of course would be definite measures. I learn by letter from my observer at Dubbo, however, that he will be able to obtain the records a long way back. The difficulty which has occurred to me as to all these records is that the velocity is wanting. I dare say a section could be taken at many places, and I have no doubt that wherever there are bridges there will be sections, but I cannot hear of any records of velocity.
165. What information have you prior to the year 1878, the date on which you commenced to publish the maps? I have the rain records for some places in the Colony as far back as twenty years, but the great majority of the records have been kept only since the year 1870. Every year the number has increased. I have here a statement showing the monthly elevations of the river at Moama, from 1863 to 1883 inclusive (*Appendix A* 2), the monthly rainfall at Deniliquin during the same period, with a break of two years, 1866 and 1867, for the reason that I have already explained—that Mr. Smalley discontinued the observations (*Appendix A* 3). The statement also shows the rainfall at Albury from 1863 to 1883, with a similar break in the years 1867, 1868, and 1869 (*Appendix A* 4). I have also brought with me a number of rain records. I have the record for Brewarrina from 1872 to 1883 inclusive; for Armidale, from 1870 to 1883; for Narrabri, from 1871 to 1883; for Bourke, from 1871 to 1883; for Inverell, from 1874 to 1883; for Bathurst, from 1870 to 1883; for Dubbo, from 1870 to 1883; for Mudgee, from 1870 to 1883; and for Orange, from 1870 to 1883 (*Appendix A* 5). I have selected these towns as bearing upon the rivers, and it is the best information which I can give the Commission as to the rainfall in these places. Further information can of course be obtained from the rain and river records.
166. I think you have at various times read before the Royal Society papers in reference to these matters? Not many; most of what I have had to say has been published in the rain maps and in the papers. The first occasion on which I called attention to a matter which has been engaging my attention for some years—the difference between the rainfall and the discharge of the rivers—was in 1879. I read before the Royal Society a short paper in reference to the river Darling and the water which should pass through it. The paper is dated August 1st, 1879. You will observe a connection between this date and the statements which I have already made. I began to keep the river records in 1879, and as soon as they came into my hands

hands I saw that the rain and river records did not accord. I wrote a short note calling attention to the fact, and showing that the water which passed down the river Darling was so small in quantity as to be utterly insignificant when compared with the rainfall. H. C. Russell, B.A. 3 July, 1884.

167. Will you kindly put in that paper with your evidence? Yes. I have on one other occasion since 1879 read a paper before the Royal Society; it was a paper upon Evaporation, but that does not so much affect the question. The observations, which had the effect of bringing the matter under the notice of those who took an interest in it, were made in connection with the rain and river observations in 1880 and since. I then said—"The width of the river at Bourke is 180 feet, and the velocity when in flood is rather less than 1 mile per hour. A few figures, which I need not give here, suffice to prove that $\frac{1}{4}$ of an inch of rain over the watershed, or $\frac{1}{10}$ part only of the rainfall, represents all the water that passed Bourke during the whole year." Several writers in the public Press, and others who communicated with me privately, took considerable exception to the statement which I then made that in such a country a third of the rainfall should be available. I am not an engineer, but I have taken the data for my statement from various engineering works. I find that in England the quantity of the rainfall passing down the rivers varies from 30 to 50 per cent.; in Germany the average is from 40 to 50 per cent. Mr. Coglan, C.E., when reading a paper before the Royal Society, estimated that in the coast rivers the average was 44 per cent., varying from 52 per cent. in wet periods to 10 per cent. in dry seasons. He is of opinion that something like 25 per cent. of the rainfall ought to pass down the western rivers.

168. Have you any information as to the quantity of rainfall which passes down the rivers in California? No. I have some of the rainfall records of California, but I have none of the river records.

169. It seems to me that the circumstances of California in regard to the rainfall nearly approach our own circumstances, and I thought that if we could obtain any information as to the disposition of the quantity of water passing down the rivers, it would be of value by way of comparison? I do not know of any such records, but there is a very good collection of American publications in the library of the Royal Society. It would be easy to consult these books; and I may mention, for comparison with those records, that in the rain-map for 1880 I pointed out that there were forty-five rain stations on the Darling watershed, and the average rainfall derived from them is 20·74 inches. This refers to the upper part of the watershed, about 110,000 square miles; and the average height of the river above summer-level was 6 feet 8 inches. This represents only $\frac{1}{4}$ of an inch of rainfall over the watershed. In 1881 the average rainfall for the same district was 18·88 inches, and the average height of the river only 9 inches, which represents a quantity of water equal to a rainfall of only 0·028, a quantity so small that it is quite insignificant. Similar facts will be found stated in the rain-maps for 1882 and 1883. I understand summer-level to mean that height of the river at which it just stops running. Since then a new gauge has been put up about 4 feet above this, and that is called navigation level—I do not know on what authority. I have not put up this gauge—I think Mr. Moriarty may have done so—but the records have been sent to me, and I have kept them.

170. What do you think becomes of the water which is not accounted for? The chief information I have had is derived of course from the rain and river measures; but I have for some years past been in the habit of collecting information from other sources tending in the same direction. I may mention a few of the facts which have come within my knowledge. In the Wimmera district, in Victoria, at a place called Saen, a well was sunk; at 250 feet from the surface the bore cut 6 feet through a tree, and a great many fruit-stones, similar to the nut plums now growing, were brought to the surface. At a further depth of 130 feet such drift as is usually found in gold mines was discovered. It is evident therefore that in this district, which may be regarded as the southern edge of the basin of the Darling and Murray Rivers, there are alluvial deposits at a depth of 400 feet. Coming north from that district, at the Goree run, near Narrandera, on the Lachlan, in sinking a well, at a depth of 80 feet boulders and other indications of a large river-bed were found. A man turning over one of the stones found a frog. On examination it was found to have no mouth, that is to say, the mouth was closed beyond recognition. The frog was put into fresh water, and in the course of a few days the mouth opened; in about a week the frog died. I remember that at Dubbo when the piers of the bridge were being sunk there were found at 85 feet from the surface trees which had evidently been in an old river-bed. All over the Dubbo flats good water is found in river drift at from 40 to 50 feet down. I was in Dubbo in March of this year. The river appeared to have stopped running; for a considerable distance, some 60 or 70 yards, there was a dry bank extending across it. Just below the bridge, where a wool-washing place has been established, I stood looking into the river, which, as I have said, appeared to be stagnant. The dirt from the wool-washing operations, however, instead of distributing itself evenly round about the place, was being carried down, and the curve showed that there was still a current in the river, although, as I have explained, there was a dry ridge extending across it. It was quite evident that there was a current of water passing in the river drift. From the Macquarie, near Dubbo, sufficient gravel to ballast a railway line for about 100 miles has been taken out, showing that there was practically an unlimited supply of gravel wash. This would seem to have been a characteristic of the river for many ages. The gravel becomes covered with a muddy deposit and is left below, the water eventually percolating through it. In the Castlereagh River a great deal of sand and gravel is brought down. More than half of the course of the Castlereagh is now filled up with drift, and running parallel to the Castlereagh there is a place called the Monkey. It is very well known in the district, and in it, at all times and seasons, water is to be obtained by sinking a small distance. This water is found in a river drift.

171. Does that run parallel? Parallel to the Castlereagh; water can be found in it at all times. It is further evident from all I can hear that it is an old bed of the Castlereagh, which has been filled up by exactly the same process as that which is filling up the present bed of the river. Mr. T. K. Abbott, now Police Magistrate in Sydney, made it his business to collect the records in connection with wells on the Liverpool Plains. He has records, I believe, of over 200 wells. A great deal of the information which he obtained was read in a paper before the Royal Society. But Mr. Abbott has collected some further information, of which he has told me. He tells me that he has found what he thinks is positive proof of an old river-bed at 80 feet below the surface, running across Liverpool Plains. In this bed the water was running abundantly in an old river drift. That appears to be only another stage of the process which is going on in the Castlereagh. To the north-east of the Darling, at Bourke, there are indications of another river-bed, from which gravel and ordinary river drift have been obtained. I think we have sufficient evidence that these rivers have choked themselves, and have gradually formed new beds. The

old

H. C. Russell, B.A. 3 July, 1884.

old river beds, found as I have said at various depths, and being full of gravel, afford a sufficient drainage to take away the water. There are one or two further facts of an interesting nature which I may as well mention here. At Dunlop Station, about 100 miles south-west of Bourke, in sinking a well at a depth of 300 feet, they passed through a sort of slate composed of sand, wood, shells, and dead fish, packed so hard that is was necessary to blast the mixture. Under this mixture a tree 18 inches thick was passed, and at 143 feet further, or 443 feet from the surface, another tree was found. These facts bear out my description of the character of this part of the country. Higher up the river there is evidence of an old river action at various distances below the surface, and here an abundant supply of water was found in other wells at 480 feet from the surface; it came up from river drift in great abundance. More recently, so I notice by the papers, a well has been sunk on the Tooralie run, and at 82 feet from the surface an abundant supply of water was found in a drift composed of granite, pebbles, and boulders; and near Hungerford's another well came into an old river drift, containing shells, lignite, stones, &c., 120 feet from the surface. These cases seem proof of river-beds at various depths. Further down the Darling we have the same occurring near Wilcannia. Water is there found in some sort of drift, and there are a number of other facts of the same character, which induce me to think that the old river beds form a means whereby a great deal of water gets away. I know that exception is taken to that view. It is supposed that water cannot percolate very fast through sand and gravel; but on the other hand, it is quite evident that the strata in the upper parts of the Darling country are permeable, and are of that character which will let the water into the ground. It is also evident that the rainfall is not accounted for in the rivers, and it is only fair to assume that it sinks down into the strata somewhere, and it cannot continue to accumulate indefinitely below—it must run somewhere. Every year there is a certain quantity of rainfall, and every year a certain quantity of water must sink into the ground, run away by some underground drains, and I think I have shown that some buried river-courses exist, and as compared with the extent of the country very few wells have been sunk, it is fair to assume that there are many more old river-beds as yet undiscovered. This disappearance of the rain-water has continued for so long a period that no storage of any capacity could possibly account for the water. In South Australia, in latitude 29°, just north of Farina, water has been found in abundance at a distance beneath the surface of 1,220 feet, and this seems from its depth to prove that the drainage goes west, for the wells are deeper as you go west.

172. *Mr. Donkin.*] That is about west of Dunlop's station? Yes. These are some of the reasons which induced me to suppose that the water must get away. No one else was writing upon the subject, and I felt that some one ought to take up the matter and to keep it going. With reference to the quantity of water which escapes in this manner, I do not think we have means which will enable us to give a definite answer. In England it has been shown that one-third of the rainfall in some districts sinks down to underground drainage. The quantity of the rainfall is measured, and from a section of the river at Bourke, taken many years ago, with known velocity I have ascertained the quantity of water passing away in the Darling. I do not suppose that the section is likely to have altered very much in the interval, but in order to get a complete answer to the question—where the water disappears, we want a number of properly made sections higher up the rivers, in each branch of the river in fact.

173. *President.*] Have you ever heard, or have you any information which would lead you to suppose that there is a discharge of this fresh water into the sea? Yes; in the western district of Victoria a considerable stream of water has been found to the south of Wentworth—I forget the exact locality,—but this water is running away towards the sea. The river is in a limestone formation. It is pretty evident on our east coast that the water gets away through the sand. On the coast to the westward of Adelaide, away towards Western Australia, there is no surface water whatever to be found. There is a considerable rainfall at Adelaide, varying, I suppose, from 20 to about 30 inches a year. We may assume that, as the land on the coast to the eastward is in the same latitude as Adelaide, the rainfall there would be similar; yet, as I have said, no surface water is to be found. The water cannot find its way into a big hole—it must get out at some point. There are some curious facts bearing upon this question. In the low peninsula of Florida, rivers, which must have their sources hundreds of miles distant, come out of the earth in volume sufficient to permit steamboats to go to their basins of irruption. In January, 1857, a submarine fresh-water river burst up from the bottom of the sea, near the south end of the peninsula, and for a whole month discharged a current not inferior in volume to the river Mississippi, or six times the volume of the Nile. This water comes from the country which is drained by the Mississippi. It is pretty evident that the water does not find its way into the Mississippi, which is, one would think, a sufficient drain for all the country. As our investigations proceed, I think that something of the same kind will be found here.

174. Have you ever heard it asserted that, at a considerable distance at sea on the Victorian coast, fresh water is to be found? I have never heard that said.

175. *Mr. Barton.*] You have perhaps heard that there is an enormous discharge of fresh water into the sea between Port Lincoln and the Great Australian Bight? I have heard of it, but I have received no particulars—I have heard only the general statement. In the country between the coast and the Gawler ranges people can tell exactly the depth at which an inexhaustible supply of water can be found. To my knowledge, if you sink a well at a time of heavy rain in this country the water will rush down it, bringing with it all sorts of rubbish and débris, and within ten minutes of the stoppage of that rush the water becomes perfectly clear, and remains at exactly the same height in the well. Endeavours have been made to reduce the depth of the water by means of pumps and other appliances, but it cannot be lowered a quarter of an inch. These wells may be found at intervals for a distance of 300 or 400 miles down the coast.

176. You have no information upon this point? I have only a general knowledge of the question.

177. *President.*] Have you any information as to wells which are not in the neighbourhood of rivers, but which are situated between various rivers in the Colony—between the Macquarie and the Castlereagh, for instance? I have a good many notes upon that question, which I will be glad to produce for the information of the Commission on another occasion. There is one fact which I intended to mention just now, with reference to the sinking of a well at Sale, Victoria. When the water was first discovered it came up quite black with leaves, dead timber, and rubbish of that kind, showing that the water must have rushed through some open space; because if that were not so the leaves and other débris would not have been contained in it. What I mean the Commission to understand is, that the water must have passed through holes large enough to admit leaves, pieces of wood, &c., and therefore, sufficient to let a great deal of water pass.

H. C. Russell, B.A.

3 July, 1884.

178. The flow of water continued in that condition for some days, I believe? Yes, several days, and an enormous quantity of rubbish was brought up. With reference to the Murray River, I should like to put in a long letter which I have received from the late Mr. Gell. (*Appendix* A 6.) He has also sent me some valuable information which he obtained in reference to the river. He kept a record for a number of years at Lake Victoria, and he has sent me a tabular statement in connection with the Murray River, from August 12, 1871, to August 12, 1874 (*Appendix* A 7.) He has also sent me a diagram showing the Murray River measures from 1871 to 1876, made at Ki (*Appendix* A 8); and a further diagram, showing the Murray River measures at Lake Victoria in the years 1863, 1864, 1866, 1867, and 1868 (*Appendix* A 9.) I think the Commission will find that these diagrams contain very useful information. I understand that the Commission desires some information as to the quantity of water falling at a particular time, and the effects of that rainfall upon rivers. One of the most marked instances of a flood occurring from a particular rainfall was recorded in February last year, on the Darling. I commenced to plot upon the map the rainfall which caused it, and which had fallen upon the Macintyre and mountains near it; but, upon further consideration, I found that I had not sufficient data for tracing the flood-waters from where they fell down the river, and that no satisfactory result could be obtained. I know nothing of the sections of the river above Bourke, or of the velocities of the current. I find that sections of the river were made at Brewarrina and at Walgett by the Department of Harbours and Rivers; but beyond this I can obtain no information upon the point.

179. If you could obtain these sections of the river and the velocities, would it assist you in giving us some further information in reference to the effects of the rainfall at that particular time? Of course I could work it out, but I should not care to do so. I think that is more in the nature of work for an engineer. For instance, the average velocity of the stream on the surface might be taken; but I know perfectly well that engineers have very different opinions as to what the actual velocity is. It depends upon where you measure the current, if you want to be particular.

180. *Mr. Donkin.*] I believe experience shows that the general velocity of rivers in the level country is about 1 mile? Yes. There is a little discrepancy in the measures given me by Mr. Moriarty. The velocity of the river at Bourke is shown at one and a half mile per hour. There are other measures of the velocity of the river made in a 30-foot flood, and these velocities show it to be something like two-thirds of a mile per hour. Taking the instances of high floods, and noting the time the flood-wave takes to get from Bourke to Wilcannia, I find that the velocity differs very much. In 1879 the velocity was 2·1 miles per hour; in 1880, 2·1 miles; in 1881, 2·0 miles; in 1882, 2·5 miles; in 1883, 2·2 miles. The rate of translation of the wave varies with the rate of rainfall. In 1882 the rainfall was very heavy, the rise in the river rapid, and the motion of the flood-wave faster than usual. I can give a few particulars of the progress of the flood resulting from the heavy rain which fell on the Macintyre. It reached Wilcannia on March 1st, having passed over 535 miles at the rate of 2·2 miles per hour—Menindie in six days, at the rate of 1·7 miles per hour. Of course after the flood-wave has stopped the velocity would not be so great.

181. The higher the flood, I believe, the less the velocity? It does not appear so.

182. *President.*] You can give us no other information as to the velocity of the river? No; of course, in reference to the velocity of the flood-wave—that is, the translation of the flood or first rush of the water—a great many measures have been taken by the Department of Harbours and Rivers.

183. You have no further information which would be of use, as enabling us to determine where the water escapes to at the heads of the Darling, either on our side or on the Queensland side of the Border? The best information on that subject of which I am aware is contained in Mr. T. K. Abbott's papers in reference to the wells on the Liverpool Plains, but it deals with a comparatively small area. I have some notes which I will bring to the next meeting.

184. Can you give us any information as to what are known as "mud springs"? On the Gilgoin Run, not far from Brewarrina, there was one of these mud springs. It was known as the Cuddy Spring; there was a slight depression of the surface, and the ground was always a sort of bog. The proprietor of the run at length determined to fence it in, in order to prevent the cattle from being bogged there, but it occurred to him that he might as well make use of any water which could be obtained from it. He set some men to work, and an excavation was made. In the first place they came across the bones of bullocks, underneath these were the bones of kangaroos and various extinct animals, and at 27 or 28 feet such a quantity of water was obtained that the men were driven out, and the well has since afforded an abundant supply. The blacks have a tradition which seems to point to the fact that the source of supply is the Darling. The tradition is to this effect,—that there is an underground current of water; whether it is an old creek which has been filled up I do not know. North and west of the Darling, in a line nearly parallel to the river, there are many others—most of them to the west of Bourke. The theory has been advanced that there is a long dyke or other geological formation which causes the water to come to the surface here, but I have no particular information about it. In many other cases attempts have been made to obtain water out of these mud springs, but the only successful instance of which I heard was that on the Gilgoin Run. In some cases water has been found by sinking wells pretty close to the springs. In most cases attempts to sink wells led to an overflow of mud which cannot be managed, and no water is obtained.

185. Have you no idea as to the direction which is taken by the water from some rivers which lose themselves before they reach the Darling? I know that they sink into the ground. For instance, the Paroo seldom or never reaches the Darling. I do not know what becomes of the water; that is a question which can only be answered when the geological formation is understood. It is a fact that water is running generally in the Macquarie and other rivers, and that it only reaches the Darling in flood-times.

186. *Mr. Barton.*] Did you say lignite? That is the description given in the papers. My own impression is that this well must have struck an old channel of the Darling. It is quite evident from the map that the drainage has been in a line something like the Darling. I believe that these mud springs are formed by water coming up from an old channel.

187. *Mr. Donkin.*] Have you any reports as to the mud springs in Queensland—they are much more prevalent there? I have no detailed information. I should mention to the Commission that I have received from Mr. John Wright a great deal of information with reference to the western rivers. I produce, for the information of the Commission, a pamphlet read by Mr. Wright before the Engineering Association of New South Wales. In this pamphlet Mr. Wright says:—"The following figures will, I have no doubt, surprise many members, but I can guarantee their accuracy. The construction of two weirs in a watercourse upon the west bank of the Darling River, at a cost of £2,990 each, would impound

H. C. Russell, B.A. 3 July, 1884.

7,000 millions of gallons of water (sufficient to supply the city of Sydney for five years), cover at flood-level an area of about 14,000 acres, extend back from the river 18 miles, and give a water-frontage of about 61 miles, the weirs being respectively 17 and 21 feet in height, and 93 and 104 feet in length, and 8½ miles apart. In another place a weir 60 feet long, 16 feet high, costing about £1,700, would throw the water back 16 miles, and impound upwards of 1,000 millions of gallons of water, and give about 70 miles of water frontage."

188. Mr. Wright was in this country for some years, I believe? Twenty years, I think.

189. I believe that he has given some information in reference to evaporation? Yes, he has given a great deal of information on that subject. He was employed by Sir Thomas Elder and a South Australian syndicate, and he has furnished some very valuable records in reference to evaporation. He told me that some years ago, when he was in the dry country, he saw a statement in the papers to the effect that Mr. Todd, the Government Astronomer of South Australia, had stated that the evaporation at the Adelaide Observatory was 6 feet per annum. Mr. Wright's impression was that that statement was exaggerated, and he determined to make an experiment in the dry country in which he was then situated—about the latitude of Bourke, I believe. He filled up a tank made of sheet-iron 10 feet 6 inches square and 1 foot deep. The result of the experiment showed that in three years the average evaporation was 98 inches; he came to the conclusion, therefore, that Mr. Todd had not over-stated the evaporation which took place at Adelaide. Mr. Wright made a number of other observations in regard to tanks on stations not far from this spot, and he says that the evaporation in these places was about 50 inches. The record kept at Bourke gives about 7 feet or 84 inches. Many squatters, writing to me, say that in the hottest months of the summer evaporation goes on at the rate of about 1 foot per month for about three or four months. Since the discussion upon this subject was initiated I have received other letters from gentlemen resident in the country, telling me that this is an over-estimate, and stating that they do not believe the evaporation to be more than 3 or 4 feet in the course of the whole year. I have been anxious to obtain some more accurate results, but for want of means I have been unable to take any action in the matter. I believe that £300 has been voted for the purpose of making experiments, but as the Appropriation Act is not yet passed the money cannot be touched. Exception has been taken to the means which we employ to measure the evaporation in the interior. It is said that it is absurd to measure it from metal vessels placed on the surface of the ground, but the conditions under which evaporation takes place are so various that you cannot get two cases which are exactly alike. You must adopt some means of measuring; if you measure from a waterhole you cannot tell what goes out of the bottom of it, and, from many points of view, I think the method of weighing a vessel containing water is more convenient. A difficulty presents itself, as soon as one attempts to measure by a graduated scale, and that is, that a man, in order to measure a depth accurately must have a certain amount of training. But almost any man can weigh water accurately. That method was adopted by Mr. Smalley. The observers were required to weigh the water every morning, and the differences from day to day show the amount of evaporation. There has been kept for about ten years a comparative examination between the evaporation from a vessel placed on the surface and from a vessel sunk into the ground; both vessels were carefully measured every day, and it was found that there was a definite ratio between them. The one on the surface of course evaporated a larger proportion of water. At some periods the evaporation from a tank in the ground is greater at night than in the day. That is of course owing to the heat radiating from the ground. The radiation of the heat carries the water up with it. The general impression in the country is that a less evaporation from a large body of water takes place; that is a point open to discussion. My impression is that it will be found that the reason there is a less evaporation from a deep tank is that it is low, and is not exposed to the effect of the wind.

190. *President.*] Is it not a fact that there is less evaporation from a deep than from a shallow tank? If there is, the reason is I think not to be found in the quantity of water, but from the fact that the water is lower down, and is sheltered from the wind.

191. What is your opinion with reference to tanks made in the dry country for the use of stock: suppose they were covered with wood, would the evaporation cease? If they were covered with wood I think the evaporation would practically cease. Of course if they were completely covered there would be no evaporation. I suggested some time ago that this would be an economical way of saving the water, but the natural reply to my suggestion was that there were no means of carrying out the plan in the back country; that is to say, the available means were not sufficient, and it would not pay to do it. I will hand in for the information of the Commission some letters in regard to evaporation, which I wrote in the course of correspondence on that subject, in the columns of the *Sydney Morning Herald*. The Members of the Commission will observe that there are one or two of those letters wanting, but it will be easy, from reference to the dates of the letters which I now hand in, to supply these omissions.

192. The information you give as to evaporation refers, I suppose, to the direct evaporation from a clear surface of water? Yes.

193. Can you give us any information as to the evaporation after rainfall on the salt plains of the interior? No; I have been for the last twelve months making experiments at the Observatory, showing the evaporation from the surface of soil on which there is nothing growing, and from a surface covered with grass. I find that the evaporation from the surface covered with grass is very much greater during windy weather. It is curious that though there is a certain amount of rapid evaporation from the earth when the soil is wet, very much more rapid than from water, yet, as soon as it becomes superficially dry and caked, the evaporation almost stops, although there is plenty of water below.

194. *Mr. Gipps.*] What was the depth of soil on which you made these experiments? 7 inches.

195. Have you heard of Greaves' experiments in England, extending over a period of fourteen years? I believe that they were made from dripping gauges. The experiments were made, I think, on a depth of 3 feet. I have read of some of Greaves' experiments, but I cannot at this moment give the Commission any detailed information in regard to them.

196. *Mr. Barton.*] The opinion of squatters to the effect that evaporation is considerably less in deep tanks than in shallow ones is based on the fact that the water is so much cooler in the one than in the other; I have received a number of letters bearing on the question of evaporation. It is a very troublesome point to deal with. No two tanks would be circumstanced exactly alike. Every variation of the conditions makes a difference in the amount of evaporation.

197. I had, at a place 20 miles from Bourke, a 12,000-yard tank, at which no stock were watered; the whole soakage and evaporation for six months was 2 feet 6 inches; the only water taken out

was

was taken by the paddymelons, and by men who desired to get buckets of water for their horses; the tank at the end of the summer was not 2 feet 6 inches lower: how do you account for that? I cannot account for it, but probably some rain fell during the six months. I have here a paper by Mr. F. J. Byerley, in which he refers to a statement made by Mr. Wright, which, however, I have been unable to find in Mr. Wright's papers. He says, "In a very valuable paper read before the Association of Engineers in Sydney, by Mr. J. Wright, an engineer of much practical experience in the waterless portions of South Australia and New South Wales, it was stated that, of the annual rainfall over the immense watershed drained by the Murray River, not more than a one-thousandth part escapes to the sea." I have tried for some years to get at the discharge of the Murray. It is a very different river from the Darling, and is in every way more difficult to deal with. In the Darling country there is a general slope. The rainfall is not much affected by the contour of the country; where it is so affected, the contour is so gradual that it is safe to take the average. But coming to the heads of the Murray you have to deal with a different set of circumstances. It is necessary to know how far the heavy rainfall extends. The rainfall on the lower parts of the Murray is about 15 or 20 inches, but on the upper parts it runs up to 60 or 65 inches; I do not know the area over which that extends. For a few square degrees the catchment of water was about 25 inches. Only a rough calculation of the quantity of water which goes down the river can be made until we obtain more information.

198. I thought that Mr. Gell had made observations of the rainfall on the Lower Murray from a very early period? From 1863 to 1869 Mr. Gell was at Lake Victoria, and from 1873 to 1874 he started again at Ki. Mr. Gell's letter which I have handed in to the Commission contains a lot of valuable information upon this point.

199. *President.*] Have you any information tending to show whether the flood area of the upper part of the Darling is known? I do not think it has ever been surveyed. I have some notes as to the extent of the flood area. I have been told that the river has been as much as 70 miles wide.

200. *Mr. Barton.*] Below Bourke, at Wilcannia? No; at Bourke. I never heard of a survey of this area.

201. *President.*] Do you know that at Bourke there is a large flood area? I have read of it; I have never been there, and have never heard of any survey showing the actual area.

202. Can you give the Commission any information as to the disappearance of water on the plains at any particular spots; the points, for instance, at which the water apparently gets away through some subterranean channels? I can give you no information derived from my own observation. Mr. William Abbott, however, has placed before the Royal Society some very valuable information upon this point, and in connection with this matter he told me some curious facts relating to the holes which are called gilgies. Into some of these holes the water seems to run away for days together; how it gets away no one knows. The impression at Dubbo is that the gilgies there are formed by a large crack in dry weather, and that in some cases these cracks extend down to porous strata, and the water gets away by that means. It may be that there are old river beds covered up with a layer of mud. If a crack were to take place in this mud there would be an open way to take the water down into the old river drift. It is conceivable that the water might escape in that way. I never heard of one of these places being dug out to ascertain what its suction was, nor have I heard of any measure being made to ascertain the actual quantity of water that escapes. I have heard that the water runs down these places for days at a time. I know of course that water escapes in this way, but it is impossible to say how much escapes.

203. Do you know of any large extent of country on this side of the Darling where, by sinking wells, you can obtain plenty of water? In the neighbourhood of Wilcannia, it is said, there is a large area in which water can be found at the same depths in a river drift extending over a considerable area. All the water is found at the same depth, which varies only with the contour of the surface. The water would appear to be passing away in the drift.

204. Have you heard that between the Murray and the Murrumbidgee the same thing occurs for a long distance? Yes; I know that that is so over a considerable area. The first well was formed there I believe in 1864. Abundance of water was found on the Lachlan by sinking at a comparatively shallow depth. Some persons imagine that there may be found in this portion of the country a sufficient quantity of water for irrigation. I was taken to task for saying that there was an inexhaustible supply of water in the west, but those who took me to task were thinking of irrigation. I never dreamed that irrigation was possible on the Darling. I do not now think it is possible. What I meant was that there was an inexhaustible supply for the wants of the country for squatting and other purposes of that description. There is not sufficient rainfall in the country to provide a supply which would be enough for the purposes of irrigation. Even if you could conserve every drop of water which fell, you would not have sufficient to irrigate the whole country.

205. Could not sufficient water be brought from some other district? In Egypt an average depth of 15 inches is required for 150 days, and I think that our western country would require as much as that.

206. *Mr. Franklin.*] But would not the rice crops require more irrigation? Perhaps; the country is hot—very dry.

207. *President.*] Is the water obtained from the wells fit for the purpose of irrigation when it is first brought to the surface? In a great many cases the water from the salt wells would not be used; I presume that for the purposes of irrigation the water would be injurious.

208. But even if the water be fresh, would it, when first brought to the surface, be fit for vegetation? I do not know.

209. *Mr. Franklin.*] In India, I believe, from 1½ to 2½ feet of water are required for the season? I cannot say. In Egypt, I believe, the quantity is 15 inches for one crop.

210. *President.*] Do you think that the rainfall in the higher parts of the Colony, supposing it runs underground, and could be obtained on the plains, would supply sufficient water for any considerable extent of irrigation? That of course depends upon what the extent is. I know of one engineer who thinks that the country might be irrigated to the extent of about a mile back from the river banks. Reports have been presented to the British Association for some years past as to the underground system of drainage in England. A short time ago I made some allusion to the subject. These reports show that there is an enormous supply of water to be obtained; and, as an instance, within an area of a few miles in the neighbourhood of Liverpool, 14,000,000 gallons of water per day are taken from a few wells. The reports also show that 10 inches of rain which percolate into the ground there would give a water supply of 143,000,000 gallons

H. C. Russell, B.A. 3 July, 1884.

gallons per square mile per annum. In England they prefer underground water for drinking purposes—it is considered more pure. The available underground supply of England coming from 10,000 square miles would keep the Darling running 25 feet above summer level throughout the year. It seems reasonable, in the light of this experience in England, to expect that we have underground in the Darling country a much greater supply than is available in England; for if we leave out of consideration all the Darling country with less than 18 inches of rain, there is still ten times the English area with a rainfall of from 18 to 30 inches to give our supply.

211. Can you give us any information with regard to the subterraneous creek which appears in the Fish River Caves? I do not think I can. At the same time I do not believe that there is any doubt that a subterranean river has produced the caves. I think I shall be able to obtain some information with reference to the floods in the Murray. I have a friend who has been a resident at Moama for many years, who will be able to give me a great deal of information about the river heights at Moama. He has taken a great deal of interest in the question, and he tells me that the great flood of 1870 arose from a simultaneous flood in the three smaller rivers which supply the Murray. It is usual for the floods from these three rivers to come down in succession, but the enormous flood of 1870 was produced by a flood coming simultaneously from each one of these rivers. You will see from Mr. Gell's papers that this flood was a long way above all the other floods, as regards its elevation. In connection with this subject I may here mention one curious fact. A few months ago the Surveyor-General of South Australia wrote to me to ask if I could give him any information as to the reason why two lakes, situated on the top of hills near the border of Victoria, had varied in elevation at different periods of the year. It appears that the waters in these lakes go through regular variations in the course of the year, and he asked me if I connected it with the rainfall. I looked at the matter very carefully, and I cannot see that there is any connection.

212. These are supposed to be lakes in extinct volcanoes, are they not? I believe they are; they go through a regular oscillation, but it does not accord with the water running down the rivers or the rainfall. There is one fact which I desire to mention with reference to wells, and that is that in several places, notably on the Kallora run, there are wells where the supply of water varies with the state of the atmosphere. That has been noticed in a number of places in the Colony; that is to say, the differing states of the atmosphere affected the quantity of water discharged. There has been a marked instance of this effect on a station to the south of Cooma—Babandarra Run. The water there in a certain creek stops running, and when it commences to run again the circumstance is regarded as a sign of rain. The explanation of this is to be found in the variation of the barometer; when the barometer falls the pressure is removed, the air inside expands and forces the water out. When a barometric depression has passed over the country, water has been known to commence running in many places. There are wells in the Murrumbidgee in which the quantity of water varies with the state of the atmosphere. There is another instance on the Gundare run, close to Coolah.

213. Can you tell us whether there is any regularity in the seasons as regards the rainfall: I believe you have given that subject special attention, and have attempted as far as possible to ascertain whether our seasons do or do not run in cycles: in a work published by you in 1877 you give statistics of the floods, as far as the records are available? As far as the records were available. Since that work was published, however, I have obtained a quantity of additional information. The work to which you refer is practically out of print, but the publication of it brought to me a great deal of valuable information. For instance, I have obtained the whole of the observations made by the late Captain King, and I also have some valuable observations by Sir William Macarthur; these would go to amplify the details of the work.

214. What is the result of your researches with reference to the cycle of seasons? After a careful examination of all the rain statistics which I could obtain, it appeared to me that the most probable cycle was a period of nineteen years. That idea was my own as far as it affected this Colony, but an attempt was made in England many years ago to show that the period there was eighteen years. A serious difficulty, however, arises in reference to this matter, and I am endeavouring to investigate it. The only records extending back for any period affect the coast districts, and many people say that the coast climate is not the same as the climate of the interior, and that these observations on the coast are no guide with reference to the interior. As a matter of fact the droughts to which we are subject seldom or never affect the whole Colony—they affect certain districts only. The interior, for instance, has recently suffered from a drought as severe as any which has occurred in this Colony for many years past, but on the coast, near Sydney, we were not particularly hurt by it. It is difficult at present to advance any definite theory with reference to this subject. I have not altered my opinion; I still believe that the period of nineteen years is the most probable period in which the seasons return. I am quite unable to say definitely what is the area over which the historical droughts extended. It is only during the last six or seven years that I have had in operation a general system for the collection of rain statistics. The year 1882 was a fairly good one, but in all the country west of the Darling there was a frightful drought. To some extent the drought existed to the east of the Darling; last year the drought extended still further to the east, and in some cases there was 50 per cent. less rain than the average. The statement that seasons recur in a cycle of nineteen years should be made in connection with this further statement, which is, that you could not find two seasons exactly alike if you were to examine through the whole of the records; it is only the general character of the seasons which appears to recur. In the year before last I published a diagram showing the variation of the rainfall in England; for a hundred years attempts have been made there to show that there are cycles.

215. In some parts of the work to which I have referred you favour nineteen years cycles, but it would appear that there are intermediate cycles of about ten or eleven years? I pointed out that the cycle which had obtained the most adherence was that of ten years, and it is a curious thing that from 1830 upwards for some years the cycle of ten years fits in very well. Old colonists believed that the seasons did recur once in ten years, but in attempting to follow out this theory I found that the cycles did not continue at those intervals—the periods varied. Mr. Tebbutt believes that there is a period of three years; that fits in very well with his own observations extending over seventeen years, but going further back it would be found that his cycle did not apply. In Tasmania for twenty-five years they had a dry and a wet season alternately, and people there began to think that they had arrived at a very comfortable state of things as regards the seasons, because they knew exactly what to do in each successive year. At the end of this period of twenty-five years, however, a change came, and the whole theory was upset. Meteorologists do not think it possible to find a cycle in which exactly similar weather recurs, but nevertheless I think it is safe to estimate the future from the past in this subject. If you look at the records in England and in this

Colony,

Colony, it is clear that from 1840 onwards, taking the rainfall, there has been a great increase in both the northern and southern hemispheres. The last three years, however, seem to show that we have passed by that. H. C. Russell, B.A. 3 July, 1884.

216. Have you arrived at any conclusion as to the cause of the wet and dry seasons: I observe that in one paper which you have written, you attribute the variation to some extent to the presence or absence of meteors? The immediate cause seems to me to be found in the oscillation of the trade winds. When the margin of the trade winds goes further south we usually get dry weather, and there is generally an abundant fall of rain in Victoria. The ordinary margin of the trade winds is in such a latitude that we get rain all over the Colony; if it goes further north and into Queensland, they have a dry season in Victoria. This is not simply a local experience—it affects the islands in the Pacific also—they are affected in precisely the same way by the oscillation of the trade winds. The cause of the oscillation of the trade winds is another question, and a very wide one. All attempts which have so far been made to show that there is any oscillation in the temperature of the world have failed. Attempts have been made to show that when the sun has the greater number of spots there is a different temperature affecting the earth than when there are few spots; but nothing definite can be made out. When you look at the data upon which you have to rely, you are met with difficulties, because the records of the temperature are not of such a character as would enable you to determine the absolute amount of heat which the earth receives from the sun, and this is probably what regulates the trade winds. As I pointed out years ago, there are some very curious facts to be observed in connection with the appearance of comets. The return of some comets has been invariably followed by a dry season. It is a well-ascertained fact that in Europe the seasons in which some comets have been present have produced extraordinary effects; one of these seasons produced a wine which is still known as the "comet" wine, from its peculiar properties. I do not believe the comet has of itself any effect; it is only an indication that there is something in the solar system affecting the atmosphere generally. There are cases on record which show that for longer or shorter periods the sun has seemed to lose its light and heating power—once for a whole year the sun did not possess its normal power—the fruits did not ripen at all. We cannot conceive of the temperature of the sun itself altering. Probably something intervened between the sun and the earth. The most reasonable explanation seems to me to be that there were meteors.

217. Was the season a wet or a dry one? I cannot say; this happened in historical times—very many years ago. So late as 1783 the earth was covered with a sort of fog for many weeks, and it was impossible to see the sun until it had risen 20 degrees above the horizon.

218. Was that fog? It may have been meteoric dust; no one knew what it was.

219. *Mr. Donkin.*] Have you any record of the hours of sunshine? I observe that a record is regularly kept in England. There is no such record kept in this Colony. The reason why I have not kept the record is that the instrument employed to take the measurement is such an unsatisfactory one. Mr. Balfour Stewart showed me the instrument which he had been using in England. It was a glass globe—a solid piece of glass—and a piece of paper was placed behind it. The sun's rays, concentrated by the globe, burnt the paper, and the distance of the burn showed how much sunshine there had been. It seemed to me to be such a loose way of taking the measurement that I did not think it worth while to adopt it. In the first place they used a piece of wood. I was shown a number of pieces of wood which had been used for a month each. Many of these pieces were burnt more than half-an-inch deep, but how much sun heat there had been no one knew. The same with regard to the paper. If a piece of paper is burnt by fire you cannot tell how much fire it has taken to burn it.

220. *President.*] Referring once more to the loss of water, here is a section of the Darling for 100 miles, showing the indentations in the banks of the river; you think that in times of flood there is a loss of water; is it possible that the water gets away in these openings? I am afraid I cannot answer that question. I know that the water gets away, but I can give you no details showing where it escapes.

221. Can you give us any further information in reference to the borings on old river beds? I have collected a great many curious facts in reference to the supply of water in the country near Bourke. In one place an abundant supply of water can be obtained from an old river bed at 82 feet from the surface; in the same locality the artesian wells go down 400 and 500 feet. It looks as though the water in these particular wells was obtained from another source.

222. *Mr. Barton.*] In many cases I have obtained water there, but it is salt: you are aware that a great deal of the water obtained in this manner is salt? I am. I happen to know that Messrs. Mann, Carey, & Co., when constructing the railway from Nyngan to Bourke, sank three wells in which the water was salt; but fresh water was obtained at Girilambone.

223. *Mr. Donkin.*] Will you give us your opinion as to the moon's influence on the rainfall—as to whether it is in any way affected by the moon when at apogee or perigee: ninety-nine men out of a hundred would say that if the moon comes in wet we may expect a wet month: can you give us any information on the subject? The nineteen-year periods are moon periods. I could show you a number of papers written in Europe and in India, some to prove that the moon has a decided influence on the weather, others to prove that it has no influence whatever.

224. *President.*] Do these papers refer to the phases of the moon? Yes, many of them—not all. I do not think the phases of the moon have any effect upon the weather, but obviously the moon has some effect. I can show you months in succession in which certain changes in the weather have taken place at intervals of seven days, then there comes a break. For ten weeks in succession there has been rain on the same day of the week; then you have fine weather. It does not follow that the influence which produced the rain did not come on the returning day when there was fine weather. The effect which the moon produces will depend upon the state of the atmosphere at the time when the lunar change takes place.

225. *Mr. Donkin.*] Do you think that large bush fires affect the weather? I think not—at least all the cases I have examined have gone rather against that theory.

THURSDAY,

THURSDAY, 24 *JULY*, 1884.

Present:—

MR. BARTON, M.P.,	MR. GIPPS, C.E.,
MR. DONKIN, J.P.,	MR. LYNE, M.P.,
MR. FRANKLIN, C.E.,	MR. MURRAY, M.P.,

MR. TOWNSEND.

W. J. LYNE, ESQ., M.P., IN THE CHAIR.

Victor Czarlinski called in and examined:—

V. Czarlinski. 24 July, 1884.

226. *President.*] You are by profession an engineer? I am a civil engineer, graduated at the University of Ghent.

227. You have had considerable experience in connection with water conservation? Yes. In 1878 I founded a technical newspaper at Warsaw, and I was called to study different questions in connection with the conservation and supply of water. At that time a Commission was appointed to take into consideration the canalization of the Vistula. The Commission was composed of German, Austrian, and Russian engineers. In studying the question as to what means should be adopted to improve the navigation of the river, they travelled upon it for a long time, but they arrived at no decision. The German Commissioners advocated that weirs should be constructed perpendicularly with the course of the river; the Austrian Commissioners recommended that weirs should be constructed longitudinally in the river bed; the Russian Commissioners abstained from making a recommendation; and nothing was done. I occupied myself with this question in connection with my technical newspaper; and being on a short visit to Brussels, I obtained from the Department of Public Works a great deal of information in reference to the canalization of rivers. I was made acquainted with everything which had been done in Belgium in connection with the canalization of rivers. I also became acquainted with the hydrological works of M. Belgraud, who was commissioned to make inquiries with reference to a water supply for Paris. This gentleman made a hydrological survey of the basin of the Seine, and by studying this work I came to see that the basis of every scheme of water conservation must rest upon a perfect knowledge of the geological and meteorological conditions of the country. By a combination of the facts revealed by geology and meteorology one can discover what becomes of the rainfall. It seemed to me that on this basis alone could it be determined what should be done in reference to the Vistula; and I could not agree with the proposal to construct the weirs, because the ground being permeable the water could not be retained, but would escape away underneath. Many rivers of to-day are very small streams compared with what they have been in previous geological epochs. A river carrying less water contracts its bed, and the weirs would have that effect. The river being prevented from overflowing would improve itself by dredging its bed. In 1880 I was appointed a member of a Commission to inquire into the merits of a scheme for the water supply of Warsaw. Before the meeting of the Commission I made a careful examination of the surrounding country. I turned my attention to the nature of the soil. It was said that the water could not be obtained from springs, and it was proposed to take the water from the Vistula—a plan which on sanitary grounds is not approved by modern engineering science. It would of course be preferable to obtain the water from another source. I was afterwards entrusted with the construction of a railway in the Russian province of Koursk. It was necessary of course to obtain a supply of water for the stations, and here again therefore I was occupied with the question of water supply. I was also occupied with a similar question at the Congress of the Imperial Russian Technological Society at Moscow, in 1882. A desire to study the hydrological conditions of Australia was the special cause of my visit here. I knew, from what I had read of the physical conditions of the country, that they differed very much from the physical conditions of European countries. In studying the geological conditions of the country, I have not lost sight of the fact that the flow of the rainfall into the rivers is determined by the nature of the soil. On impermeable soil the water flows over the slope into the river. On permeable soil the water, instead of taking a course over the surface, sinks straight down until it reaches a lower stratum of impermeable ground; it goes thence to the natural watercourses which drain the country. This is the general rule; the exceptions are very numerous. In impermeable country in which there is no fall, the water of course cannot escape, but remains in pools until it is evaporated. Now, with reference to the quantity of rainfall which is available for practical purposes, if you take a river basin a great part of which is impermeable and level, the rainfall is not apparently of much benefit to the river. In calculating the rainfall on the whole area of the basin, a deduction must be made for the fall on that portion of the basin on which the water is physically prevented from entering the river. The water which flows into the river is that only which falls on an impermeable slope or on permeable ground in connection with the river-bed. In calculating the quantity of water therefore which should pass through a river, the area of the rainfall must be limited by the physical and geological conditions of the country. I have here a rough sketch of two old beds of the Murrumbidgee, at Narrandera. On reading the evidence given by some witnesses before the Select Committee of the Legislative Council, in reference to the Pastoral Dams Bill, I found the statement that certain creeks were not running to but from the Murrumbidgee. This led me to suppose that the country must be permeable. The features of the bottoms of all the valleys are in permeable ground, of a slightly convex shape. The water falling on the permeable soil feeds the river from underground. At the time of flood the water rises where it meets with the least hindrance; it overflows, and deposits loam and stone on the river bank; and that is how the bottom of the valley comes to have a convex shape. This map shows the river bed as it now exists. The middle line shows an old bed, and there is yet another bed. You see that the river becomes smaller and smaller. The more ancient bed you find compact gravel, and in the river-bed you will find gravel and sand mixed. The *régime* of the river has undergone a great change. Some time ago the bottom of the river valley was exactly over impermeable strata; the floods must have been very heavy, and have carried the gravel down from the hills. The river appears to have become smaller with the change of climate which appears to correspond with the epoch of an entire change of climate in Europe. As the rivers become smaller, the floods are not so violent. They may be as heavy as preceding floods, but they are not so violent in their course down the river, for the reason that the river bed has been filled up with permeable material. Again, the river is not only fed by water which runs over the slope—it is fed by water from underground, which runs with diminished speed. In this case the *régime* of the river is changed—it no longer fills up with gravel—it forms marshes. The map indicates a swamp; that swamp is due to the *régime* of the present river—the river is fed underground. I have on the same plan a section of a river in France.

France. Here you have the same causes producing similar effects. At a certain point you find a swamp; the *régime* of the river has changed, and of course with a change of *régime* you must adopt different methods for the conservation of water. Take the Yanko Creek, an outlet from the Murrumbidgee. Apparently the water runs down, but it is not so. The ground underneath is impermeable; the water running through permeable strata stops at impermeable ground. When the water rises, it rises only with the level of the water permeating the strata. If the ground were permeable the level of the underground water would not rise, the water would sink perpendicularly, or would run for a few miles over an impermeable stratum and then disappear. It is the rising of the underground water which makes the river appear to flow in the direction indicated. It would be no use to attempt to conserve this water by means of dams, because as soon as the dry season commenced and the underground level commenced to go down, the water in the dams would also sink. If the water were running on impermeable ground the case would be different,—the only cause of the diminution of water would be evaporation. Here is a section of a principal valley and of a secondary valley on permeable ground. The water goes down until it reaches an impermeable stratum. The principal river naturally drains the water, and the level will differ with the rainfall. The nearer you go to the summit of the watershed, the nearer to the surface of the ground will you find the water. As long as the water is over the river-bed of the secondary valley you will have water in it. When that level ceases to be fed by new rain, the level of the watercourse in the secondary valley will lower, and finally the watercourse will dry out. In this kind of ground you will never find springs on the sides of the valley through the reason that in permeable ground the water goes down perpendicularly. If the lower impermeable stratum cuts the principal valley at a point higher than the river-bed this will be entirely in impermeable ground, and at the separation line of the two strata will occur a number of springs forming a water-level (*niveau d'eau*), as you may observe in the valleys near the tops of the Blue Mountains. The greatest source of supply, however, will be found at the intersection of the impermeable stratum with the bottom of the secondary valley. I mention these matters to show the great difference between permeable and impermeable ground. If you have artesian strata the case is different. The present condition of the Paroo may arise from two causes: its outlet being perfectly level it may inundate the country, or it may sink into a permeable stratum. The continuation of the first impermeable stratum may be at such a depth from the permeable ground that the water would go underground direct to the sea and would feed no other rivers. There are cases in France in which rivers flowing over impermeable strata almost disappear when they reach permeable ground, and re-appear at a distance of some miles.

228. Between the two points the river is lost? Yes; the impermeable strata run nearer the surface. There is a remarkable case at Mount Jura. The mountain is composed of several parts, one of which is called the Forest de la Serre and another the Vignoble. The vine is the only agricultural growth which is to be found there. Then there is a plateau, and afterwards a higher table-land. The first table-land is rendered remarkable by an enclosed basin, that is to say, there is a depression on the plateau forming a water reservoir, the bottom of which has never been reached. The water sinks through an oolitic formation until it reaches the Oxford clay; about 20 miles further on it forms the source of a little river which is never dry. There is no apparent connection between the two sources, and it is only by a knowledge of the strata that the water can be traced. Unless the strata are known, you cannot depend upon finding water by sinking a well at a particular spot. It was only by a study of the geological formation that it became known that this particular river had its source in the basin, and that by sinking a well at a given spot a certain quantity of water could be obtained.

229. *Mr. Townsend.*] What is the difference between the level of the basin and of the outlet below? About 3,500 feet. I have made a sketch, showing that there exists a strong connection between meteorological phenomena and geological features. The lines represent the height of the rainfall; the line representing the rise in the river takes the form of a curve. If the line takes the direction indicated at this point on the plan, it means that the river rises slowly; it could be ascertained how many days after the rainfall this rise takes place, and the time which the rainfall will take to reach a certain part can also be calculated. It will be found that on permeable ground the line rises slowly. In the case of rainfall upon impermeable ground, a sharp rise in the direction of a line is indicated—it jumps suddenly upward. This is especially the case in winter, but in summer we have the same phenomena, only the height of the river is much less, because the loss by evaporation is much greater, and there are rains which make no difference whatever to the river, even on the permeable ground. On the maps indicating the rise and fall of the rivers Darling and Murrumbidgee you will observe that there is, in the shape of the curves, a great difference at Hay, and from that point you have a curve slowly rising and slowly sinking; at Bourke the curve jumps straight up.

230. *Mr. Gipps.*] Perhaps the difference is caused by difference of grades? I do not refer to the quantity of rain. The shape of the curve illustrates purely the way in which the water reaches the river, whether under permeable or over impermeable ground.

231. *President.*] It does not matter whether the water comes from snow or rain? No; in either case there is no difference. What influences the *régime* of the river is the undersoil. The water, of course, requires more time to sink down and then flow upon impermeable underground to the bottom of the river-bed than it requires to flow over a slope of impermeable ground direct into the river. This is shown by the diagram—in some cases you have a sharp curve, in other cases the curves are very gradual. It points to the fact that one river is better than the other, because in the one case you have a natural storage of water on the basin of the river.

232. *Mr. Gipps.*] The declivities of the river are totally different. The declivities of the Darling are 4 to 6 inches to the mile; the declivities of the Murray are 2 inches in 20 or 30 feet? That proves that in the one case you have to deal with a permeable ground. The water reaching Bourke from the mountains so fast as to make such a rapid rise in the river is another proof that in the one case the ground is permeable and in the other impermeable. The pressure of the water coming in suddenly and rushing over the ground makes the river rise to the height indicated.

233. *Mr. Barton.*] May it not be due to a certain extent to the tropical rain? The absolute height is, of course, dependent upon the amount of rain, but it is important to consider the way in which the river rises, that is to say, whether the curve rises suddenly or whether it rises gradually.

234. *Mr. Gipps.*] Here is a case in which the river at Murrumbidgee shows a very sudden rise, whereas the oscillation of the river at Bourke is gradual? My observations apply only to the general nature of the curves.

V. Czarlinski. curves. Wagga is, of course, in a different position; it is on impermeable ground, and that would account for the sudden jump.

24 July, 1884. 235. *Mr. Gipps.*] At Wilcannia the curve is even for some distance? It is not marked between certain parts; it then rises to a certain height, and it apparently maintains that height—you have no rise or fall of any importance; if there should be a great rain on the mountains it would jump up—the line would suddenly rise, but it would soon return to its former level.

236. *Mr. Franklin.*] Can we take it as an established rule that where we find the greatest rise of flood the ground is less permeable than at those parts where the river flows at a lower level? That is one of the signs by which you may judge of the impermeability or permeability of the ground. In the first instance you must have regard to the height of the river, and then you must pay attention to the way in which the river attains that height and goes down. If on reference to a good map you see a number of rivers, you may be pretty well sure that the ground is impermeable, whereas in permeable ground the rivers are chiefly underground. The Darling is mostly on impermeable ground; but there is an absence of slope. The rain which falls between Nyngan and the Darling stops where it falls; if it rains for a short time, the whole country is flooded for a few days. The country is practically level; if there were a little more incline you would find a number of little creeks. If you had no rain they would soon run dry. In the case of creeks on permeable ground, however, it does not necessarily follow that because the beds of the creeks are dry there is no water; it is merely an indication that the level of the water underground has been lowered. Therefore, if you are acquainted with the nature of the ground, you will know whether it is or is not possible to find water when the bed of a creek is dry. In the one case you can construct dams; in the other case you can deepen the bed by dredging, or you can sink wells.

237. *Mr. Franklin.*] We want to discover whether it is possible to intercept the water in the tributaries of the Upper Darling, to ascertain without doubt the permeable portions of the country, to there divert the water by means of canals, and to let it into the river again at a point which we know to be impermeable? Whatever plan you adopt for the conservation of water must be based upon a thorough knowledge of the geographical features of the country. I have here a rough sketch of the geological features of a portion of the country. There is near Bathurst a patch of tertiary, beginning near the tributaries of the Macquarie. Here you have a patch of tertiary situated between impermeable strata. When in such a case you have found the permeable strata, you can by studying its direction ascertain to a certain extent where water may be found.

238. *President.*] As regards the tributaries of the Upper Darling, the best way in which to discover the locality of the permeable strata, I suppose, would be to discover the rise of the river at certain points after certain rains? In my opinion, water gauges should be erected on the different tributaries of the Darling.

239. Suppose it were thought possible to conserve a large portion of the rainfall on the Darling by the construction of a reservoir, do you think we could find a sufficient area of holding ground? That is a matter which requires to be studied on the ground. If you could find a sufficient area of impermeable ground, and conveniently situated, I think the scheme would be a good one.

240. *Mr. Barton.*] We found that on all the banks of the tributaries of the Darling there has been a constant deposit of alluvial silt until the banks are raised, and the drainage is naturally at some distance from the banks of the river; we thought that it would be well, if possible, to take the water from this natural drainage ground to a holding ground lower down? There is one thing which should not be lost sight of when you are taking into consideration such a scheme as you mention, and that is that some rivers form an almost impermeable bed by the deposit of mud; if you cut through the mud you will find that the ground is quite permeable.

241. The whole of the tributaries running into the Darling have near them ground which is permeable at points 2 ft. 8 in. or 3 ft. from the bed which they have formed by the mud? On the 12th January, 1865, 4½ inches of rain fell throughout the whole of that country. It was an enormous rain—sufficient to drown horses in the paddocks. It did not make a difference of 1 inch in the water on the Darling, and that shows very plainly that the ground between Nyngan and Bourke is permeable. About three weeks after the date I have named the river was flooded. That is a startling fact, and should be taken into consideration in connection with any scheme you may adopt.

242. In referring to the rapid rise at Bourke you said that the ground there was impermeable: I do not think that is the case—it is impermeable at the head of the river? In studying the rivers you must not consider one portion alone, or you will arrive at wrong conclusions. There are cases in which the impermeable ground at a certain point on a river will cause the water to go at a great speed over permeable ground. You may think that the ground there is impermeable, but it will be found to be permeable. If you refer to a geological map of the Seine, you will see that the ground over which it flows is alternately permeable and impermeable. If a considerable area of impermeable ground is followed by a small section of permeable ground, the *régime* of the river on the permeable ground will be the same as on the impermeable ground. The cause is to be found not in the local conditions, but in conditions which are to be found higher up the river.

Mr. David Waugh called in and examined:—

Mr. D. Waugh. 243. *Mr. Franklin.*] I believe you have invented an excavating machine? Yes.

24 July, 1884. 244. Has it been in practical work in this Colony? It has only just started, and under very disadvantageous circumstances. I supplied a machine to Mr. Crombie in Queensland, but it has not yet been worked, on account of the dry weather and the want of water.

245. Has the machine done any practical work in any other Colony? One has just started work in South Australia.

246. Can you give the Commission a short description of the machine, and the nature of its working? The machine combines the two processes of the present system of excavating, ploughing, and scooping. My idea was to perform both these operations by one machine, by making the scoop strong enough to tackle solid ground, and in adopting steam-power to work it.

247. Hitherto the machines have worked when the face has been already made? We propose now to form a face with the machine, and to take out earth at depths of 6 feet 6 inches. When one depth of 6 feet 6 inches has been stripped a smaller depth may be operated upon.

248.

Mr. D. Waugh. 24 July, 1884.

248. Would it be available for tank-sinking over a large area? I think that with certain improvements the machine could be made suitable for that purpose.
249. What quantity of earth could be removed in one day? I have machines for small power, and machines for large power. I should say that a machine worked with 4 or 6 horse-power would give an excavation of 500 yards a day. The machine which I supplied to Mr. Crombie took out 60 yards in one hour at Eveleigh. The cost would be about 3d. per yard. The theoretical cost is considerably under that.
250. At what do you reckon the expenditure all round per diem, that is to say, for the wages of the men, and reckoning also for wear and tear; suppose the machine were to be taken into a distant part of the country, what staff would you require to work it? Two men and a boy would be ample to work the machine. Men's wages would be about £1 15s. I should think £1 would cover the cost of water; a load of wood would last about a couple of days; oil and sundry other expenses would amount, at the outside, to about 5s. a day. Of course I am not now including camping expenses. Putting aside expenses of that character, I should think that the total cost would be at the rate of 1½d. a yard.
251. But under the worst conditions of inland carriage what would the cost be? At the very outside, 4d.
252. Of course in large excavations there would be the disposition of the spoil to be considered? That would increase the cost.
253. *Mr. Murray.*] I suppose you would have to use drays to take it away? Yes. Mr. Crombie's estimate, including the carting of the spoil, was 5d. per yard.
254. *Mr. Franklin.*] What is the smallest cross-section of a cutting which you could make; could you work at certain levels given? It would finish completely off to any gradient. We can dig to a depth of 20 feet, and we can deliver all to the surface; and the improved machines will be able to work on almost any slope.
255. What is the smallest area of space upon which the machine can work? The machine can stand in about 8 or 10 feet, and the slope might be 1 in 1, and you would not require a steeper slope than that.
256. *Mr. Donkin.*] Would 4d. per yard include the making of the face in the first instance? Yes.
257. *Mr. Franklin.*] How do you deliver the material into the cart? It is delivered into the cart at the top of the bank from the scoop.
258. What is the cost of wear and tear? The machine is so far in its initiatory stages. I have not had sufficient experience to justify me in answering that question.
259. When the machines have been established some time I suppose you would be able to import them at a cheaper rate? I think there is very little doubt of it. The machine is yet hardly past its experimental stage.
260. *Mr. Donkin.*] You say Mr. Crombie took one of the machines? Yes; but he was only able to erect it. A drought then set in, and there was not afterwards sufficient water to fill the boiler.
261. Is not the wear and tear rather heavy when you are working heavy soil? The point of the spade is the only part which is worn.
262. *Mr. Franklin.*] Would the machine be suitable for the cutting of small distributaries? The Commission will see from the plan which I produce (*Appendix* B) that it will be suited to cutting at any depth. The cutting seen in the plan may be widened by stripping along the side. You can start upon the surface of the ground to make the cutting which is indicated by this plan, and then there is no necessity to move the machine so much.
263. What advance would be made per diem in the cutting illustrated by this plan? If the machine were about 4-horse power, the average delivery would be about 400 yards per day. That cutting would be 20 feet wide by 9 feet deep.
264. Supposing the cutting were 4 feet deep, with a slope of 1½ to 1, how much advance would be made per diem? Roughly speaking, the machine ought to advance 130 lineal yards a day.
265. *Mr. Gipps.*] What would the machine excavate in that time? About 400 yards.
266. *Mr. Donkin.*] Have you tried this machine for cutting canals? Two are in use in South Australia.
267. Could it have been used, for instance, for the cutting of the canal from the Nepean to Prospect? Only in some parts.
268. *President.*] What would be the average cost per diem? About £3 a day. The actual expenses in working the machine and the fuel would not amount to more than £2.
269. The canal described by Mr. Franklin would cost then about a shilling a lineal yard? About 6d., I think.
270. *Mr. Franklin.*] In some cases it would be necessary to carry the spoil forward to form banks in the formation of the distributaries—I suppose in that case you would have to cart the spoil? I think the better plan would be to dig deeper down at the necessary places.
271. *Mr. Donkin.*] You say that you have completely overcome the difficulty which has hitherto existed in regard to the cutting of the face? Yes; I have a small machine for cutting drains about 3 feet deep by 12 feet wide. It will be completed in about a week, and I will have it in operation at Waterloo, at the tannery of Messrs. Geddes Brothers.
272. *Mr. Franklin.*] That machine will be specially suited to the cutting of small drains? Yes, on sloping ground. The stone which I now produce was cut through by one of the machines working at Liverpool; I produce it in order that the Commission may form some idea of the capabilities of the machine when working in ground in which stones are plentiful. Stones will not interfere with the action of the machine.
273. *Mr. Barton.*] Did not that stone disturb the cutting? The spade was slightly affected, but it did not affect the machine.
274. *Mr. Franklin.*] Has there been no experience of the practical working of the machines in South Australia? The machines were taken there in wet weather, and under the most disadvantageous circumstances; they delivered 60 yards an hour; they are in use in a very rainy district, and as they are digging vertically it has been decided to stop the work until the dry weather comes on.

THURSDAY, 31 *JULY*, 1884.

Present:—

MR. BARTON, M.P.,	MR. GIPPS, C.E.,
MR. DONKIN, J.P.,	MR. MURRAY, M.P.,
MR. FRANKLIN, C.E.,	MR. TOWNSEND.

R. L. MURRAY, ESQ., M.P., IN THE CHAIR.

Mr. Victor Czarlinski called in and further examined :—

Mr. V. Czarlinski. 31 July, 1884.

275. *Chairman.*] Can you give us any further information with respect to the subject of your examination at the last meeting of the Commission? I have brought with me a hydrological map of the basin of the Seine, in connection with which there are diagrams showing the rainfall in the basin. The watershed of the Seine is divided into the basins of the different tributaries of the river. The diagram which I have now before me shows the rainfall by daily records in the basin of the Seine proper. It will be observed that the level of each of the meteorological stations is given. The diagrams also contain the average rainfall at each of the stations, together with the average rainfall of the whole basin of the main river.

Hydrological map of the basin of the Seine, and diagram of rainfall.

276. *Mr. Donkin.*] What is the average? The average rainfall in the basin of the Seine proper is 26 inches, but the discharge of the river is only 12 per cent. of that rainfall.

Rule in regard to rainfall.

277. What is the rainfall at the heads of the river? It would be about 27 inches—a difference of about an inch. As a general rule, the further away from the sea the rainfall decreases, but the higher you go the greater is the rainfall. This is also true in the case of the tributaries of the Seine.

Influence of rain on rivers.

278. What is the general height of the heads of the river above the sea? About 2,000 feet. You will observe that some of the rainfalls have no influence whatever upon the rivers. This is particularly the case with reference to summer rains—the June and July rains. The rivers not only do not increase, but the level goes down.

Point of saturation of soil.

279. How do you account for that? The soil is not only permeable, but it is dried by the heat of the summer. You require a great quantity of rain before the river can rise. The soil has to be filled to a point of saturation. It is very necessary, therefore, in connection with this matter, to ascertain the description of soil with which you have to deal upon the banks of the rivers.

Hydrometrical service.

A permanent hydrometrical service has been established in the basin of the Seine, and maps are printed every year. These are sent to the engineers of the Public Works Department, to the district engineers, and so on.

280. *Mr. Gipps.*] Do the diagrams which you are now exhibiting show the average mean depth at any particular locality? They represent the height of the river at one locality. There are several stations in the basin of

River gauge.

each of the tributaries, and the different diagrams show the height at each point. The river gauge is fixed a little higher up than the junction of the two rivers. This is done in order that the height in the tributary

Maps showing quality of water.

may be ascertained independently of the influence of the state of the principal river. Maps are also published showing the different qualities of the water throughout the year. The black groundwork shows that the water is impure, and as the groundwork becomes lighter and lighter the increase in purity of the water is indicated. If the water comes from an underground source it will be much more pure than that which flows from an impermeable slope, for the simple reason that the water which flows over the slope will carry with it loam, leaves, and all kinds of rubbish, whereas the permeable ground is a kind of natural

Geological map.

filter. I have here a geological map showing the different formations to be found in the basin of the river. It will be observed that they take the form of a fan. You have the old formations at the top, and they gradually descend to the sea-level, where you find the newest formations. The colouring of the map shows the permeability and impermeability of the soil. The light colours indicate permeability, and the dark tints indicate impermeability.

Division of the province of Champagne.

281. *Mr. Donkin.*] Judging from that then, the river is only impermeable at the source? No, there are other parts in which impermeable ground is to be found. Here, for instance, is the province of Champagne. It is specially divided by its geological and hydrological features into two parts. One is known as the dry Champagne country, and the other is known as the wet Champagne country. In one part you have on the surface a number of little rivers and creeks. The soil is very wet throughout the year. When you come to the higher cretaceous soil the water disappears. It is the most sterile portion of the whole French soil. The impermeable stratum runs very deep underneath it. Here is a similar map showing the number of creeks and rivers, from which you may judge of the permeability or impermeability of the soil. You may observe from this map the effect of the oolitic and the cretaceous formations upon the existence of rivers. The exterior features of the country show very clearly the distinctions between the character of the soil. As I have already said, the dry portion of the Champagne country is perfectly sterile.

Underground water in soils of different nature.

282. What is the Burgundy country like? That is only a part of it. It is only an oolitic formation, and that of course is not so permeable as sand or chalk. There is a great distinction between the permeability of the two descriptions of soil. In sand the underground water level is continuous. In the oolitic formation you may have plenty of water, but it will exist only in separate underground streams. You may sink for a well at a particular spot and find no water, whereas a few yards further you will find plenty. The water runs in the crevices. In connection with the geological features of the basin of the Seine you will observe green sand. You cannot very well see it from the map. That sand obtains its supply from the oolitic formation which adjoins it.

283. *Mr. Townsend.*] Can you give us any idea of the width of the outcrop of the green sand formation? I have no papers here which will permit me to do that.

284. You are not aware of the extent from your own knowledge? No, I cannot say exactly. There can be no doubt that the green sand is fed by water coming from the other permeable strata. This is plain

Artesian well at Grenelle.

from a diagram in the hydrological work of M. Belgrand, in reference to the water in the artesian well at Grenelle. The diagram illustrates the levels of two rivers, and it shows that in one part the water being at nearly the same level comes from the permeable ground to the green sand.

285. What is the width of the whole outcrop of permeable strata from which the water is obtained? This map is on the scale of 16 kilomètres (about 10 miles) to the inch. You can form some idea from that of the extent of the permeable country; I should think it was about 40 miles across. The whole of that area feeds the green sand.

Mr. V. Czarlinski. 31 July, 1884.

286. You referred the other day to a cretaceous formation north of the Darling—I do not know whether you intended to refer to chalk; I have no knowledge of a particle of chalk in this country: does not a cretaceous formation convey to your mind the idea of chalk? Not necessarily: there may be lime and sand.

Cretaceous formation.

287. I read in this morning's paper a description of a cretaceous formation, in which there is sandstone alternating with shale: would you consider that a cretaceous formation? That depends upon the nature of the shale.

288. There is no lime? That may be brought underground. It is not stated on the geological map what kind of cretaceous formation is to be found to the north of the Darling, that is to say, whether it is the older formation or whether it is the newer formation.

Permeability of cretaceous formation.

289. *Mr. Donkin.*] Are you aware that on the Queensland maps this country is marked sandstone? I observe that that is so upon some of the maps of the Rev. Tenison-Woods. It is important to know of what kind of cretaceous formation the country is composed. Some parts of this formation are quite impermeable; other parts are perfectly permeable.

Different degree of permeability of tertiary soils.

290. But the formation may be permeable and still not be cretaceous? Quite so. The map of the basin of the Seine shows in the tertiary formation the eocene and the miocene series. In these formations you have two half permeable soils, five perfectly permeable soils, and four absolutely impermeable soils. I think the rain and river maps which I have produced might be improved by including an additional column showing the speed of the water, at certain points of which the river section should also be given. If that were done, you would be able to calculate the daily discharge.

291. Have you been out to the Bogan? I have been only as far as Nyngan.

292. *Mr. Barton.*] Have you seen any part of the Darling? No.

293. *Mr. Townsend.*] Was the geological section which you produced at the last meeting of the Commission an imaginary one? It was merely a rough sketch which I made to illustrate the formation.

M. Belgrand's hydrological survey.

294. *Mr. Donkin.*] Referring again to the hydrological map of the basin of the Seine which you have produced,—how far back do the records extend? M. Belgrand's survey was the first survey of the kind which was made. The river records commence in 1854. The results of M. Belgrand's hydrological survey were published in 1873.

Similar surveys in France.

295. Have similar surveys been made of other rivers? The French Government recognized the importance of the information contained in M. Belgrand's report, and the report was made to facilitate a supply of water for Paris. It was thought that it would be of great value as a basis for other descriptions of hydraulic works. Other engineers were commissioned to make similar surveys of the Department of Jura and of the High Alps. These surveys also have been published.

Staff employed.

296. *Mr. Townsend.*] Have you any idea of the staff employed in the preparation of the maps? A number of persons were employed. The Government commissioned an engineer to make the survey, and they gave him the authority to obtain information from any Department in the Service. He was commissioned to make a report upon the information which he obtained in this manner.

297. *Mr. Donkin.*] Did you in the first instance come to the Colony with a view to obtain information? I was attracted by the special features of the country. The physical features of its soil and the condition of its rainfall are quite different from those to be found in other countries. I came here about eighteen months ago, for the purpose of study. I went in the first instance to Mr. Russell, to obtain from him the rain records. I intended in the interests of science to form diagrams from these records and from the results of my own observation.

Hydrological survey in Belgium.

298. Have there been no hydrological surveys in any country with the exception of France? Yes; they have been made in Belgium. In all cases the surveys are chiefly based on the permeability or impermeability of the ground. M. Belgrand's work practically started a new department in the science of hydrology. In the work to which I have referred he describes it as an application of geology to the arts of engineering and agriculture.

299. That was the first work which treated of the permeability and impermeability of soils? Yes, it was the first work which co-ordinated the facts of meteorology and geology.

300. *Mr. Franklin.*] M. Belgrand appears to have condensed into a report upon one river, the kind of information which we wish to obtain with reference to the whole of the rivers of this Colony? I do not think you could do better than follow the plan adopted by M. Belgrand, taking also the plans adopted in the hydrological surveys at Mount Jura and the High Alps.

The rainfall passing down the Seine.

301. *Mr. Donkin.*] You said that the rainfall on the banks of the Seine was about 26 inches, and that only about 12 per cent. of that rainfall passed down the river: how do you account for the difference—have you allowed any percentage for soakage? Yes; the soakage varies in different seasons and in different places. In the Mediterranean country, which somewhat resembles that of Australia, the soakage is greater than in the north of France. An experiment made in summer, in connection with 104 millimètres of water, showed that 103 millimètres had evaporated, and that there was only one millimètre of soakage.

302. *Mr. Donkin.*] Was that shown by the percolation of water? They employed a gauge, the evaporomètre, Piche.

Evaporation.

303. What is the evaporation in the summer months on the banks of the Seine? It differs very much between various points. In some places the evaporation is greater even than the rainfall. In one place there was a rainfall of 45 inches, and an evaporation of 4½ feet.

Evaporomètre Piche.

304. *Mr. Franklin.*] Have they an established rule upon the river for ascertaining the evaporation? The evaporomètre, Piche, is used. It is a very small instrument, and also very simple in construction. It is a small glass pipe.

305. *Mr. Townsend.*] Is it perfectly reliable? It is the best instrument which they have been able to obtain, and of which hydrologists have any knowledge.

306. *Mr. Franklin.*] It has been suggested that in the outlying portions of this country some practical test should be applied, such for instance as inserting shallow tanks on the surface of the ground, from which the natural evaporation could be taken: what is your opinion? The application of the evaporomètre has been thought equally practicable and more reliable. The instrument consists of a glass pipe about 1 foot in length, the diameter being about the third of an inch. One end of the pipe is closed, the other end is open and is fitted with a small spring. The pipe is graduated to show the 300th part of an inch. You turn it up, fill it with water, and cover it with a small piece of specially prepared blotting paper; this is put over the end of the tube and it is closed with the spring. You prick the blotting paper in the centre with a needle.

Mr. V. Czarlinski. 31 July, 1884.

needle. When the blotting paper has soaked full of water you mark the height of the level in the pipe, and by subsequent observations, say three times a day, you will ascertain the evaporation which has taken place.
307. *Mr. Donkin.*] How do you prevent the discharge from the pipe to the blotting paper becoming excessive? There can be no discharge; there is only evaporation. This instrument is supplied to all the meteorological stations throughout France. It is used in connection with the thermometer. You can make experiments in different places and in different conditions.
308. But it is a fact that no water can come out of the tube except that which is evaporated? That is so.
309. *Chairman.*] Where can these instruments be obtained? You may obtain them in Paris or also in London. They are very cheap; I do not know the exact cost. If you were to have these instruments at all your meteorological stations, you would in two years' time have a perfect knowledge of the amount of evaporation which takes place in every part of the Colony, excepting of course the evaporation which takes place from plants. The instrument has been known for about ten years. I may be permitted to mention here another experiment which has occurred to me, and which I think would enable you to follow up underground currents of water. I do not know that it has yet been tried. I think you might employ the telephone with very useful results. It is an undoubted fact that the rushing of water makes a certain noise. Mr. Russell told me that at a certain place in New South Wales you can, by putting your ear to the ground, actually hear the water rushing underneath. The water, however, may be at some depth at which you cannot hear it, but by the application of the telephone and the microphone the sound might be brought sufficiently close to enable you to detect an underground stream.

Use of the telephone for following up subterranean currents.

310. We may gather from what you have said then that it will be necessary for the Commission to have made a thorough geological survey of the country, to have meteorological stations fixed in every part of the Colony, and water-gauges at sections of the rivers, showing the quantity of water going down, and for the measurement of the velocity, also that we should employ instruments for measuring evaporation at these stations: I suppose it would be necessary that this system should be continued? Certainly. My opinion is that if you intend to have made an efficient hydrological survey you must appoint some one specially to do that work. You not only require the information which you can obtain from the different Departments, but it is absolutely necessary that the person commissioned to make the hydrological survey should go through the country and make a personal observation.

Personal observations.

311. *Mr. Gipps.*] We should have to employ a scientist, and the work you have mentioned would occupy him some years—is not that so? I am not of that opinion. I think you could have prepared in about two years the description of report which you would require. The person commissioned to make the report could make a certain amount of personal observation, and he could edit a great deal of valuable information obtained from the different Departments. This report having been presented, it would be necessary to maintain hydrological surveys. Progress reports would be presented, and by and by you would be in a position to complete a map.
312. *Chairman.*] How long do you contemplate remaining in the Colony? I cannot say.
313. *Mr. Donkin.*] Were you in any way connected with the hydrological survey of the Seine? No; I obtained my diploma in 1872, a year before M. Belgrand's work was published. I have been connected with hydrological works in Belgium.

THURSDAY, 7 AUGUST, 1884.

Present:—

MR. DONKIN, J.P.,
MR. FRANKLIN, C.E.,
MR. GIPPS, C.E.,
MR. LYNE, M.P.,
MR. MURRAY, M.P.,
MR. M'MORDIE, C.E.
MR. TOWNSEND.

W. J. LYNE, ESQ., M.P., IN THE CHAIR.

Mr. George Gordon, C.E., examined:—

Mr. G. Gordon, C.E. 7 Aug., 1884.

314. *President.*] You are a civil engineer? Yes.
315. You have had considerable experience in India prior to coming to these Colonies? Yes, eleven years.
316. Will you be kind enough to state the nature of your experience? I was engaged on irrigation works, which were nearly finished when I left—the Madras Irrigation and Canal Company's works.
317. Were you engaged for any length of time? Between ten and eleven years.

Experience in water-works and irrigation.

318. Were you engaged on any other works in India except those at Madras? No, not in India.
319. Where were you engaged before that? On the Amsterdam water-works, and I was connected with some drainage works in Holland.
320. Have you been engaged on other works of a like nature elsewhere? In Victoria, on irrigation works and water-works. I was Chief Engineer of Water Supply in that Colony from 1872 to 1878.
321. How many years is it since you came to Victoria? I came in 1872.
322. And ever since you have been in Victoria you have been engaged on water-works? Yes, up to 1878. After Black Wednesday I was not engaged on any special work by the Government, but I was engaged on other water-works in Victoria.
323. You were engaged on waterworks, but not for the Government? Not for the Government, until 1880.
324. Did you prepare any schemes for water supply during that time when you were engaged under the Government of Victoria? I carried on the Coliban water-works; I finished the Geelong works. A good many country towns were supplied with water, and I had the supervision of the works carried on by the local bodies.
325. Did you prepare the plans for the schemes being carried out for the local bodies in Victoria? For most of them, generally in conjunction with a local engineer, but not in all cases. Some of them were prepared independently of me; I merely superintended them.
326. Did you prepare any scheme for diverting some of the water from the Goulburn River in Victoria? Yes, two schemes—one for supplying water for domestic purposes and for stock, and the other for irrigation. These were prepared in conjunction with Mr. Black, and the first is being carried out.
327. Where are these works being carried out by local bodies? The Goulburn River scheme is one, and several others were recommended in our reports. There were nine reports.

328.

328. Can you tell us the system under which the Victorian Government have these schemes carried out? The first step was to appoint Mr. Black and myself to report on the feasibility of diverting the water of the rivers Goulburn, Campaspe, the Loddon, the Avoca, the Wimmera, and the Murray. Then Parliament passed an Act enabling the Government to form Water Trusts, and several Trusts were formed for the purpose of carrying out the schemes we proposed. Mr. G. Gordon, C.E. 7 Aug., 1884. Water Trusts.

329. Who prepared the Murray scheme? I did, with Mr. Black. That is what is called the Gunbower scheme. These Trusts generally applied for a loan to carry out our schemes, but they made considerable additions in order to complete them and to distribute the water more closely than was intended. We had intended to give a supply of water so that no part of the country should be more than 3 miles distant from a tank or watercourse. Gunbower scheme.

330. That was in the north-eastern district? North of the Dividing Range, on the northern plains.

331. And how far west did it extend? To the Wimmera. There was one scheme west of the Wimmera, but it was only proposed to supply water there by collecting the surface water and sinking wells.

332. Not from any river? No. The Wimmera cannot be diverted westerly, and the small tributaries are not permanent enough to be made use of.

333. Is there any other provision in Victoria to carry out the works except in the way you describe, namely, by Trusts, and by amalgamating local bodies? Some of these Trusts were formed by making the Shire Councillors members of them. Where the Trusts are comprised in one Shire the Shire Councillors become members of the Trust. That is the case in the Swan Hill Shire, the St. Arnaud Shire, the Stawell Shire, and the Lowan Shire, which last is the one west of the Wimmera, where there are only wells and tanks. Shire Councillors as members of Trust.

I produce a map (*Appendix D 1*). The water of the Wimmera is diverted by means of a weir, first at Glenorchy, into Swede's Creek, leading to the Richardson. There is a cutting above the weir to Swede's Creek. Diversion of the Wimmera to Swede's Creek and the Richardson.

334. About what distance? About a mile, I think, is the length of the cutting.

335. Is that carried on in Swede's Creek? Yes, in a natural channel, improved in places. The creek sometimes spreads out.

336. Is there any canal besides this cutting? Not for the Richardson. Where Swede's Creek disappears as a creek a shallow cutting is made which leads down into the Richardson, in which it is continued, extending as far as Buloke. Instead of letting it spread over the area of the lake, it is confined in a small portion of it by a little cutting and a dam at the south end of the lake. In 1870 the lake was 6 miles in length by 3 in breadth. In 1852 it covered an area of 10 miles by 6. It was generally dry, except in years like 1870.

337. Now what is the state of the lake? There is a good supply of water in the part cut off.

338. What becomes of this water then—has it an outlet? No, the lake has no outlet. No more water need be admitted after the river is filled to this point, and if a flood came down it would pass into the body of the lake.

339. Then the water brought from the Wimmera is simply brought in such quantities as to supply Swede's Creek and the Richardson river down to the lake? Yes.

340. What becomes of the surplus water? It is not admitted, but if it were allowed to enter it would go into the lake.

341. Along the Richardson River there are dams at different places? Yes, and some more are proposed to be constructed.

342. *Mr. Gipps.*] What kind of dams? Timber weirs.

343. Fixed weirs? Some are fixed and some are not fixed altogether, because if a part were not made movable they could not be opened sufficiently in cases of flood. Weirs.

344. You always keep the channel clear by them? Yes.

345. *President.*] Where these weirs are placed across the rivers, are there off-takes to distribute the surface water over the country? In some instances there are. There is to be one at Baneyna to run the water into a lake in Avon Plain. Off-takes.

346. There are no others on that river? No, I do not think that any are proposed, but several dams are proposed to be erected on the river.

347. What size is this off-take? I do not know; it is not surveyed. I do not think it would be more than 5 feet deep there.

348. Would it be an open cutting, or masonry with regulators? There will be a timber sluice at the upper end.

349. *Mr. Gipps.*] Would it be a covered timber sluice or open? The design is not made yet, but probably there will be a bridge with a sluice under it.

350. *President.*] What size are the cuttings down Swede's Creek and the Richardson River for carrying the water off? The cutting from the Wimmera to Swede's Creek has a bottom of about 12 feet in width. Size of cuttings.

351. What is the minimum fall? One foot in a mile, and it has a uniform fall for the mile. The fall in the creek varies. Incline.

352. Do you know what is the sectional area? The greatest depth of cutting is 11 feet; but I am speaking from memory. Sectional area.

353. And what discharge of water is there? The sluices are opened just as they need water or not, and it will depend on the depth of water going over the weir at Glenorchy. When the water is level with the crest at Glenorchy it begins to flow down this cutting, and they can raise the crest of the Glenorchy weir, which increases the water in the cutting. It is therefore constantly varying. Discharge.

354. Do you know the maximum discharge? It is not intended to send down more than 3 feet in depth. Maximum discharge.

355. *Mr. Gipps.*] What will be the sectional area at a depth of 3 feet? About 60 square feet of water.

356. *President.*] Is the water taken off immediately above the dam at Glenorchy? It is about 100 or 150 yards above it.

357. Is there much deposit of silt about the outlet? Very little as yet. The Wimmera brings down a great deal of soil, but there is no appreciable deposit in the mouth of the cutting. Deposit of silt.

358. There is no irrigation going on? No, none contemplated. In the Wimmera scheme the water is not sufficiently regular or sufficient in quantity to do much in the way of irrigation. The floods are very heavy, but irregular; they come down suddenly and last but a short time; they occur sometimes in April and May, and sometimes not till August. Floods of the Wimmera.

Mr. G. Gordon, C.E. 7 Aug., 1884.

359. What other schemes have you planned? The next diversion is the Dunmunkle Creek. That was also a natural overflow, but only in times of the greatest flood.

360. From the Wimmera? Yes, from the same place. Years ago the squatters cut a small channel about a quarter of a mile from the river, in order that the floods may enter the creek at an earlier stage. That channel has now been slightly enlarged, and is taken off immediately above the Glenorchy weir.

Dunmunkle Creek.

361. How is it regulated? By a sluice, in the same manner as the other.

362. Is the fall broken at all? Yes, at one or two places. There are drops put in where the natural fall was too great. They have falls of about 1 foot 8 inches. They are all timber, because there is no stone about there.

363. Is any of the water at Dunmunkle Creek diverted at the falls? No, the falls are in the first part of it.

364. About what distance down from the weir? Water is diverted to the east about 15 miles down.

Length of Richardson Creek.

365. What is the length of the Richardson Creek? Between 50 and 60 miles.

Length of Dunmunkle Creek eastwards.

366. At 15 miles below Glenorchy where water is taken off, the Dunmunkle Creek on the east side extends what distance down? About 40 miles.

Natural channel.

367. By means of a canal? Yes, partly a natural channel and partly cuttings.

Width.

368. Of what size? About 4 feet bottom width.

Depth.

369. I suppose it varies in depth? Yes, but I think it is not more than 6 feet deep at any time. No volume is fixed, because they must take what they can get.

Slope.

370. What slope is this? It is 1½ to 1.

Nature of country.

371. What sort of country is it in? It is a sort of light yellowish clay in most places, and in others it is black soil.

Puddling of banks.

372. Is there any provision made in the banks where there is black soil by puddling to retain the water? No, the water is nearly always under the surface; in other places there is a little soakage, but not sufficient to necessitate puddling.

Distribution of water from creek.

373. Where is the water carried to, and where does it go to from the canal? It is taken up by dams across the creek, and diverted to the tanks alongside the creek, and the lower portion which is not yet finished will probably finish in a tank.

374. *Mr. Townsend.*] It is pretty well taken up before getting to the end? Yes, the cuttings are only where it is not defined; but one cutting was made in order to keep higher ground where the channel came too much to the east.

Duration of supply.

375. *President.*] In these channels is there sometimes a sudden supply, and is the channel sometimes dry? It becomes dry every year, probably from November until May. We can hardly hope for more than six months' supply.

376. Do you find that, after a drought and when the water begins to run again, there is a loss of supply? No, there is no great loss of water; I have not measured it to ascertain how much—there has not been time to do that yet.

Off-take called Minyip branch.

377. Are there any other off-takes? There is one on the west side, about 4 miles down the creek, called the Minyip branch.

378. It is diverted by means of a regulating sluice on both channels? Yes.

379. How far does this extend? At present it extends about 30 miles.

380. That, I suppose, is along the old watercourse? Yes, the old watercourse has disappeared in many places; in most years it is difficult to trace it—on ploughed ground you cannot see it at all; it is only in places that are not cultivated that you can trace where it is by a little water, or by the grass being a little greener.

Water in main branch of Dunmunkle Creek.

381. The water in the main branch of the Dunmunkle Creek is carried in the same way? Yes, but the channel is better defined than in the branch creek.

382. How far does that extend? Down to a place called Watcher, about 40 miles.

Athens Channel

383. What other scheme to the west is there? The next is called the Athens Channel.

384. Is that from the Wimmera? Yes.

385. From a weir lower down? Yes, about 15 miles lower down.

386. That is taken from the right bank of the Wimmera? Yes, following the old natural channel down to Murtoa, about 18 miles. Another branch of the same channel is taken off about 4 miles above Murtoa.

387. By means of a dam? No, by bifurcation of the channel. These works are more or less in progress. The Glenorchy weir was built about four years ago, before the Trust was formed by the Shire of Dunmunkle, and was taken over by the Trust. The west branch runs north about 20 miles.

Position of canals.

388. Are the canals made parallel with the watercourses, and at various distances from each other? Yes; the object being to divide the country into nearly equal sections each watered by a creek or channel.

Slope of country.

389. Is the country of a favourable nature for carrying out the scheme? Yes.

390. What is the slope? The slope of the country is 4 feet in a mile to about 2 feet or nearly. The greatest fall is at the beginning of these creeks.

Yarranbereik Creek works.

391. What is the next work? The Yarranbereik Creek works.

392. That is still westerly? Yes, it is a natural outflow from the Wimmera.

393. And follows an old channel? Yes, which is only filled in flood-time; it runs for 60 or 70 miles, and ends in Lake Coorong.

394. How is it diverted from the Wimmera? By a small weir called Yarranbiack weir.

395. How is that weir constructed? Of timber.

396. Like the others? Yes, but it is smaller, being only about 4 feet in height.

397. What is to be the cost of that weir? I do not know; I can give you the cost of the others. This was constructed many years back by the Horsham Shire Council.

398. Are these weirs provided with under-sluices in a line with the off-take? No.

Cost of weirs.

399. Can you give the cost of any of these weirs? There is a list of some of them. (*Appendix D 2.*) The cost of the one mentioned as Dooen Weir was £3,300. I have taken the sectional area of the river at the site of the weir as a measure of the cost, giving it in terms of that area, *i.e.*, cost per square foot. Taking a rough estimate, and taking into account the height and length of the wings, it comes to from £1 10s. to £4 10s. per square foot of sectional area of the river. What is under the bottom I have not taken into account in the measurement; that varies so much that I cannot say what it is.

400. *Mr. Townsend.*] And how much is a cubic foot of timber? About 4d.

Mr. G. Gordon, C.E. 7 Aug., 1884.

401. *Mr. Gipps.*] What would be the cost of the weirs per running foot? I have not reckoned out the cost per lineal foot, because they are so different in height? The site of the Glenorchy weir was chosen where the banks were high, so that there should be no chance of extreme flood going over the banks and turning the wings.

402. Are the abutments as high as the top of the banks? Yes.

403. *President.*] The Yarranbereik channel is small as compared with the others? Yes, it is smaller than Swede's Creek channel, but it is larger than that of the Dunmunkle Creek, though not so large as the channel of the Richardson River.

404. What off-takes are there? There are weirs at intervals of every few miles, having sluices in them, for the purpose of sending the water down to the people below before it is impounded.

Objections against weirs.

405. Have any objections been raised by the people occupying the lower ground? The people of Horsham objected to the Glenorchy weir, but it was under a misapprehension, and the objection was withdrawn when it was found that the sill of the off-take would be level with the sill of the weir.

406. Do these off-takes take off only flood-water? Only flood-water; but the Yarranbereik weir can be raised a foot higher than the sill of the sluice. There will be a notch left in the movable part, so that no complaints can be made by the people down below.

Dooen weir

407. What further works are there? The next is Dooen weir.

408. That is the one described by you as costing £3,300? Yes. There is a channel through the swamp for about three-quarters of a mile in length. A steam-engine lifts the water about 50 feet. The reason for raising the water was that it was not possible to distribute it by gravitation.

409. What is the cost of everything connected with it? I am not prepared to say from memory, but will supply it. (*Appendix D 3.*)

Pump.

410. What description of pump have you? A three-throw pump.

411. What quantity of water is it capable of discharging? Six hundred gallons a minute.

412. What is the horse-power? A nominal 40-horse power.

413. *Mr. Gipps.*] Who is the maker of the pumps? They were made at Ballarat, by a man who makes mining pumps.

Circular reservoir.

414. *President.*] The work is in a state of progress? The pumps are finished, but the work on the channel is only in progress. It is a circular reservoir of 50 or 60 feet in diameter, and partly excavated and partly raised above the level of the ground.

Supply of Horsham.

415. What is the next off-take? It is for the supply of the town of Horsham, and is erected at the cost of the Shire.

416. Is there any further distribution down the river? No, not yet.

417. In carrying out this work, do you find the supply of water below the weirs and off-takes is affected much? It is affected in a low state of the river, but not at times of flood—the river then flows over the weir.

Conservation of flood-waters.

418. You have no works to conserve the flood-water? None except the weirs.

419. There are no reservoirs in this scheme? No; when we conserve water, it is distributed in excavated tanks of about 1,500 to 3,000 cubic yards each.

Source of the Wimmera.

420. Where is the source of the Wimmera? On the north slope of the Dividing Range—the Pyrenees and Mount Cole. (*Appendix D 4.*)

421. Was it ever contemplated to intercept the water higher up above Glenorchy? Yes, but the country has not been properly examined yet. The only available places are of course alongside the river, where the land is very valuable, and there is likely to be a good deal of opposition to its being taken for the purpose of works of this kind.

Area of floods.

422. Does the water spread to any great extent above Glenorchy in time of floods? No; it is confined in the channel. It flows out a little to the south side, but at the Glenorchy weir it does not overflow the banks.

423. Have you been in the country above the upper tributaries of the Darling? No.

Area of country.

424. What area does this country which you have been referring to cover? About 2,750 square miles; that is from the off-takes downwards.

425. *Mr. Franklin.*] What is the area above the dam? I have it as far as the Yarranbereik, not to Glenorchy; it is 790 square miles,—that is above the large off-takes. Below that point there are 550 square miles, which is called the Western Wimmera. We do not include it at present as necessary for the supply of the channels described, but it is supposed to remain for the scheme which will embrace the lower part of the river.

Private property

426. *President.*] How do you manage when going through private property, as to taking up the land? There is a compensation clause in the Public Works statute which is incorporated in the Water Conservation Act. There is always an attempt to settle matters in a friendly way; if that is not successful, then there is a resort to arbitration.

Payment of water rate.

427. Do the persons benefited by the supply of water pay a rate? It is intended that they shall do so, but there is opposition to the payment at present. The payments are not supposed to begin until the people are thoroughly supplied; that is, the interest on the money expended on the works shall not be demanded until then.

428. Then the Government are at present supplying the water and bearing the cost? They supply the water and get no interest on the outlay during construction.

Formation of Trusts.

429. Are the local Trusts governed by any central body? No; before a Trust is formed an application is sent in to the Government, and the Trust is really formed by the Governor-in-Council, after an examination of the country and an estimate of the probable cost of the scheme. Then the amount of the required loan is fixed, but it can be increased from time to time if the Government choose to sanction it.

Loan.

Cost of water supply per acre.

430. Can you give an idea of the cost per acre over the whole area supplied with water by this scheme? It has cost about £116,000, and it is not considered complete. The area covered is about 2,750 square miles.

Rainfall.

Wimmera floods.

431. *Mr. Gipps.*] Have you ever calculated the amount of rainfall that comes down the river? No, I have no actual measurements of the Wimmera floods; I had to assume it in reference to a good deal of the Wimmera, but I have ascertained it in reference to other rivers. It varies a good deal. You will find the subject dealt with in one of the papers to be sent to you in connection with the north-western canal scheme, and also in the Board's Report on the Wimmera scheme. (*Appendix D 5.*) I made use of all the particulars I had five or six years ago in making the calculation. Previously to that I had made careful observations near Sandhurst, and found the available supply was one-sixth of the rainfall.

Available supply of the rainfall.

Mr. G. Gordon, C.E. 7 Aug., 1884.

432. *President.*] Have you any idea of the cost per acre over the area the works supply with water, or have you worked it out? It is about 1s. 4d. per acre.

433. Were you troubled much by the nature of the soil in the places where the works were constructed? No, not in the district I have spoken of. In the Richardson and Avon the water is salt in the summer.

Salt incrustation in lakes.

434. *Mr. Townsend.*] Have you never seen the salt incrustation in the lakes the Wimmera crosses? Yes, but I do not think it is so visible there as at Swan Hill. The flood-waters are perfectly fresh. The Wimmera is pretty brackish at the mouth in summer.

Evaporation.

435. *President.*] Do you find the water affected much by evaporation? It is not much noticed in the channels, but there has been so little time to make observations. We have made observations on evaporation over a good number of years. It was about 42 inches in the year from the surface of water. That was at Malmesbury, which is an exposed bleak part of the country.

The Gunbower scheme.

436. Are you preparing any scheme in connection with the Murray River? Yes, that is being carried out; it is called the Gunbower scheme in the Board's Reports, and is being carried out by the Swan Hill Water Trust.

Supply for pastoral holdings.

437. *Mr. Franklin.*] Is not provision made on the tributaries to supply pastoral holdings? Yes; on all the natural channels there are waterholes, and they are maintained sometimes by raising the lower bank a little.

438. You have no means of raising the crest of the weir by shutters? Yes, at Glenorchy and some of the other weirs there are movable planks or shutters.

439. Do you think it possible in taking off the sides to carry the water above the surface of the country? Yes, to a small depth.

440. Sufficient to distribute water by gravitation? Yes, small channels could be treated in that way.

Retentiveness of soil.

441. It is a question whether the soil of our country is sufficiently retentive to suit the scheme you speak of? Soils get retentive afterwards. At one or two of the places where the bank and the weir are above the surface, squatters' old dams, above the creek, have been retained and furnished with by-washes or weirs, and these retain the water.

442. *President.*] Have you any knowledge of the New South Wales river system? I have seen the Darling, but only from Wilcannia downwards, and the country about Deniliquin. There is a river there called the Edwards, which I have seen again lower down.

443. *Mr. Murray.*] Would the system adopted in Victoria be suitable here? I think so.

Floods of the Darling.

444. *Mr. Franklin.*] Above Bourke the north-western country is flooded after heavy rains? I do not think there have been floods in Victoria so heavy as those on the Darling, if they are so heavy as I have read of their being.

Retention and distribution of flood-waters.

445. It seems that if the very large area of water in case of floods could be retained and its distribution regulated, we might avoid the ill effects of floods and provide for a plentiful supply of water when it is needed? I think the Murrumbidgee is very much like the Murray in character, and that much of the flood-water of that river could be saved.

Storage of storm-water.

446. *Mr. Townsend.*] If all the available storm-water were stored at the Wimmera before it gets to the flat country, would there be sufficient for an irrigation supply? There would be in most years, but I do not think there would be found a convenient place for storing all of it.

447. How many acres in the mile could you count on to supply for perfect irrigation, leaving other water to supply the stock? I am not prepared to say directly, but will send an estimate. (*Appendix D 6.*)

Scale for maps.

448. What do you recommend as the best scale for the maps to be used in the examination of the country for a scheme of irrigation? About 2 inches to the mile is a very convenient scale.

Success of the Wimmera scheme.

449. *President.*] Does experience so far in Victoria induce you to go on with the works you have commenced? Yes. This Wimmera scheme with regard to which you have been examining me has been extremely successful—people are much pleased with it. Some of the others people profess not to be pleased with, because they do not serve for irrigation purposes, for which they were not intended.

Alterations in designs or plans.

450. Have you seen any reason to correct errors in designs or plans to any large extent? Not to any great extent in the general design; in fact most of the Trusts applied for loans to carry out our schemes. In details some alterations have been made, but the general scheme has been carried out in most cases.

Surveys.

451. On what system of survey do you base the preliminary operations? We make a reconnaissance of the country, and get all the levels that may have been taken for the railway surveys. Where it was necessary we sent a surveyor to take a few lines up and down the district under examination, and then we sketched in roughly what channels were likely to be required.

452. Did you take levels connecting the rivers? Yes; we divided the country into a series of areas, according to the river systems, and took levels right across each at intervals, and also along what we knew to be the probable line the channel would take.

453. Were these lines of survey levelled and plotted? No, the areas were not plotted as sections; the levels were marked on plans. Most of the country in the northern plains is subdivided by roads and selection fences, and the surveyors mark what is necessary to plot on the plans.

Floods on lower part of the Wimmera.

454. Is the Wimmera liable to heavy floods on the lower part? The town of Glenorchy has been flooded, and I think the town of Horsham, but I am not sure.

Rising of river-bank by silt.

455. Is there not a perceptible rising of the banks of the rivers, caused by silt? Yes, there is generally a fall from the river bank outwards. In many cases it is a dead level; in others there is a slight fall.

456. Is the construction of the weirs legalized? Yes, under the new Act.

Area supplied with one cubic foot of water.

457. *Mr. Gipps.*] How many acres is it estimated that a cubic foot of the water so arrested under your system will supply? I calculate when they have a good system of irrigation 4 acres per cubic foot per minute. Pasture land will take a good deal more water.

458. That is the Indian scale? In some cases, but it varies in all countries.

459. *Mr. Donkin.*] You have not actually distributed any water through the summer months from the Wimmera? No, there is none to distribute.

Fixed weirs with movable crest.

460. *President.*] Which do you consider most applicable, movable or fixed weirs? Fixed up to a certain height, with a movable crest.

461. *Mr. Gipps.*] That is where there is a declivity? It is to make room for the flood-water. In most cases we have had to deal with flood-water of such large volume that we could not take the weir to the top of the bank unless it was made movable.

462. In all weirs you think a portion of them should be movable? Yes, in rivers subject to floods we make them movable, although it may make the expense much more.

463. *President.*] In reference to the weirs, would the fixed part cause the river to silt up? I think so, in some cases just immediately above it. Mr. G. Gordon, C.E.
464. But will the silting cause any great trouble or damage? I do not apprehend any trouble from it. 7 Aug., 1884.
465. How many separate schemes have you similar to those on which you have given information this afternoon? There are six in progress: the Goulburn scheme, the Gunbower or Murray scheme, the Loddon scheme, the Avoca scheme, the Wimmera scheme, and the Broken River scheme. There are more Trusts than those, but these are the only schemes which deal with the rivers.
466. *Mr. Murray.*] Are those on the south side of the range? No, on the northern.
467. *President.*] If you apply your scheme to the Murray you would have to put a movable by-pass to leave the river navigable? If a weir were placed in the Murray you must, in order to make the river navigable, have an opening in the weir down to the level of the bottom of the locks at the end of it.

FRIDAY, 8 *AUGUST*, 1884.

Present:—

Mr. BARTON, M.P.,	Mr. LYNE, M.P.,
Mr. DONKIN, J.P.,	Mr. MURRAY, M.P.,
Mr. FRANKLIN, C.E.,	Mr. M'MORDIE, C.E.,
Mr. GIPPS, C.E.,	Mr. TOWNSEND.

W. J. LYNE, Esq., M.P., in the Chair.

Mr. George Gordon, C.E., further examined:—

468. *President.*] You produce a report of the various schemes on which you have been engaged in Victoria? These are the reports of the Victorian Water Conservation Board. There are two reports subsequent to these, but they are on irrigation. Mr. G. Gordon, C.E. 8 Aug., 1884.
469. Which is it that you say deals with irrigation? The Gunbower scheme; but it does not profess to irrigate by gravitation; but as a large quantity of water is brought into the natural channels, people pump it up for themselves. Gunbower scheme.
470. Have you the scheme here? Yes. There is a natural outflow of the Murray River at a point 16 miles below Echuca; that outflow forms into a creek which runs nearly parallel with the Murray 4 to 6 miles back from that river. Outflow of the Murray.
471. And flows a distance of 45 miles? Yes. There are two other outflows from the Murray which join that creek, one called Deep Creek 10 miles below.
472. Where is the other one? At Bagot's Creek, which is well defined, except at the head, and the Trust have opened up the heads of both creeks to let in early flood-waters.
473. How are the heads protected? At present only one is protected, but all are to be protected with sluices. At present this is hardly necessary, but it is intended to clear the channel at Gunbower Creek and then put a sluice at the head. Protection of heads.
474. Will these sluices be carried to the bed of the creek, or is it only intended to meet cases of inundation? They will shut off the full depth of the creek. It is purely to save expense in waste weirs at the dams. There are here some old station dams and others, and if they have the water well under control at the head, waste weirs will be a matter of more easy construction, otherwise they would be rather troublesome. Sluices.
475. Where the water is controlled by sluices, is there any visible diminution of water below—when heads are formed, is there a diminution of natural water in the original river-bed, so as to give rise to complaint? It was complained of at first in the case of Glenorchy River, but under a misapprehension; they did not understand what amount of the water was to be taken away. We insist on the sill of the sluices in most cases not being lower than the sill of the weir, so that only a certain proportion of the water may go down the channel.
476. Is the water that goes in these ordinarily dry channels simply the flood-water? Yes.
477. And the cuttings are deepened? That at the head of Gunbower is not yet deepened to the full extent intended. Deepening of cuttings.
478. About what season of the year does most water come into that creek? Generally it begins to flow in June and July, and lasts till November of the same year. Season of greatest water supply.
479. That is during the spring? During the full supply of the Murray.
480. Are there many weirs constructed along that channel? At present only one, and these are only earthen dams, and some of them are to be converted into weirs. They are old dams; there is one new one near Gunbower station. Number of weirs.
481. Has the water been diverted from that channel anywhere along its course? There is a natural outflow from the Gunbower channel at Gunbower into the Kow Swamp; that flows out again by the Box Creek, which runs nearly parallel to the Gunbower Creek. Outflow from the Gunbower channel.
482. Does the water come along that channel at the same rate as the water along the Gunbower Creek? It takes a little longer when the water is from the river. The swamp has also a supply from the Pickaninny Creek. Supply from Pickaninny Creek.
483. Where does that come from? From the neighbourhood of Sandhurst.
484. That is part of the Gunbower scheme? The Gunbower scheme includes the Kow Swamp, but not the Pickaninny Creek.
485. Where is the water taken out of the Kow Swamp? Down Box Creek, which joins the Pyramid Creek. That is also a local drainage, and they flow into the Loddon near Kerang. Outlet of Kow Swamp.
486. Do they flow by a natural channel? Yes; it is very ill defined in some places. In some places there are water-holes, in others dams cross it.
487. The connections are made always by cuttings between the waterholes? They have not done it yet: there is a sufficient flow to give all the water they need down the Box Creek for domestic use and stock watering. Connection between water-holes.
488. How much further? It flows to the Loddon below Kerang. After Pyramid and Box Creeks join they flow into the Loddon at that place.

489.

Mr. G. Gordon, C.E. 8 Aug., 1884.

489. Are these head waters to this scheme? No, except for the lower part of the scheme. Here the Loddon water is included after the creeks join, and the waters are taken off and fill a chain of lakes known as Lake Charm, the Middle Lake, Reedy Lake, and Kangaroo Lake, &c.

Area of lakes.

490. Have you any idea of the aggregate area of these lakes? No; they are shown on the map with distinct boundaries, but they are merely a collection of swamps; though Lake Charm is a well-defined deep lake.

Extent of irrigation.

491. To what extent has irrigation been carried on, if it all? It has been carried on by private individuals from these creeks by pumping. I have a table of irrigation results for last year.

Irrigation results.

492. All in connection with this scheme? No; irrigation all over the Colony; it was got up by the Government Statist. The scheme I have been referring to is named the Swan Hill scheme.

Particulars about Swan Hill scheme.

493. Will you give the particulars connected with it? The table shows that the number of acres irrigated is 5,580; the total number of farms, 1,241; the total number of farms on which irrigation was practised, 88; the cultivation, 92,648 acres of not irrigated land, and 5,580 of irrigated. It gives the results, but they give an imperfect idea of the effects of irrigation, being only the results of one year. There is an average giving the produce on land irrigated and that on land not irrigated; but that applies to all the Shires. (*Appendix D 7.*) It was not a favourable year to show the advantage of irrigation, because it was a particularly good year for rain. The wheat not irrigated was 13·11 bushels to the acre, irrigated 16·31; oats not irrigated 24·44, irrigated 33·30; barley not irrigated 14·70, irrigated 31·35; potatoes not irrigated 2·87 tons, irrigated 5·80 tons; beet, mangold-wurzel, &c., not irrigated, 17·32 tons, irrigated 19·29 tons; hay not irrigated 1·13, irrigated 1·67 tons; chicory irrigated 5·59 tons, not irrigated 8 tons; hops not irrigated 8·78 cwt., irrigated 10·49 cwt.; tobacco not irrigated 3·14 cwt., irrigated 4 cwt.

Water raised by centrifugal pumps.

494. How is the water raised for irrigating by this scheme? Generally by centrifugal pumps.

495. Not by gravitation? There is no irrigation by gravitation in the Gunbower scheme.

Fall.

496. What is the fall between the two points, the head works and where the water joins the Murray again? Where it goes into the lake, which is really the end of it, there is a fall of 67 feet.

497. That is about 40 miles? About 45 or 48 miles.

498. The average being about 1 ft. 4 in. per mile? About that.

Area supplied.

499. What extent of country is supplied by that water? 578½ square miles.

Cost.

500. Do you know the cost? Up to the present it has been £39,000; but that includes the supply of two towns, Swan Hill and Kerang.

501. Will you roughly average the cost per acre? It is about 2s. Each person who wishes to irrigate takes the water out of the creek in front of his land.

Irrigation by pumping.

502. How is the 5,580 acres irrigated? That is done by pumping.

503. *Mr. Donkin.*] Have they been charged anything? Not yet. No rate has been struck, the works being incomplete. The Swan Hill Trust and the Trust of Gunbower cannot levy a rate for irrigation, but they can sell water.

Measurement of water.

504. *Mr. Gipps.*] Is there any measurement per acre of the water drained off for irrigation? No.

Rate.

505. *Mr. Franklin.*] Has it been suggested that in levying a rate the measurement should be for irrigated land per acre? No power has been given to sell water for any purpose by measure.

506. *Mr. Donkin.*] Would there, by this scheme, be a sufficient supply for a number of farms which went in for irrigation? It could be made sufficient, as it all depends on the creeks flowing from the Murray.

Size of cuttings.

507. *President.*] About what size are the cuttings? Only about 8 or 10 feet bottom at the heads.

Constitution of Trust.

508. How is the Trust constituted with regard to the Wimmera Trust—is it similarly constituted? The Wimmera Trust comprises three Shires; this Trust is comprised in one Shire.

509. I mean the constitution of the Trust and its power? The power is the same, but the constitution slightly different, because there is only one Shire in the Swan Hill Trust.

Flow of water in the creeks.

510. *Mr. Franklin.*] If the water running into these creeks flows down the natural channel when there are freshets, does any portion of the water recede again as the freshets discontinue? No.

511. It does not run in at the heads? No, it cannot return to the river—so long as the river is above the level outlet the water flows down the creek.

Beds of the creeks.

512. In that case the beds of the creek are rather higher at the inlet than the bed of the river? Yes, much higher.

Supply of creeks.

513. *Mr. Barton.*] These creeks are only supplied during floods? During floods only.

514. *President.*] I should think the supply would be about September, when the snow water is coming down? September I think is the month when the water is the highest. I made an average of the various heights, and I think August and September are nearly equal.

Irrigation by gravitation.

515. *Mr. M'Mordie.*] With a fall of 67 feet, or 1 foot 4 inches per mile, would it not be possible to irrigate by gravitation? It would in some places.

516. Then what are the difficulties of a gravitation scheme being carried out? The principal difficulty would be the want of co-operation among the farmers themselves, the difficulty of obtaining land for the channels, and the cost of the main channels.

Difficulties from persons living lower down the diversion point.

517. *President.*] Has there been any difficulty among the persons living lower down on the ground that the water has been diverted or stopped? Not in this Trust, as regards the works constructed by the Trust. Threats have been made of cutting some of the old dams.

Flood outlets.

518. *Mr. Gipps.*] You say that the mouths of these creeks are higher than the beds of the river? Yes.

519. And when the floods recede the water does not run into the creeks? No.

520. Is there no declivity? From the river?

521. No; the declivity is along the bed of the creek *from* the river towards the bed of the creek? These are outlet creeks from the river.

522. Not natural watercourses or tributaries? No, all flood outlets.

Initiation of Gunbower scheme by Shire Council.

523. *Mr. Donkin.*] Was the work in the Gunbower scheme initiated by the Shire Council or by the Government? It was at the instance of the Shire Council, who made application to be formed into a Trust to carry out the scheme which Mr. Black and I proposed; but now, I may say that a large number of the people would like to see an irrigation scheme substituted.

524. I understand that the Gunbower and these other creeks are ana-branches? Yes.

Water gauges.

525. Have you a gauge at these creeks or at the Murray River to ascertain the body of water passing down? No, we have not gauged the creeks. There is a river gauge at the Echuca, another at Swan Hill, and one at Koondrook, near Kerang. I had the Murray gauged at Koondrook during the driest summer they had had for a great many years.

526.

526. In opening up these different channels is there any tendency to silt? No; there must, however, be a slight silting somewhere, because the water flowing from the Murray is tolerably muddy, and lower down the creeks it is clearer.

527. I understand that there is a chain of ponds? These creeks with the water-holes remain the same.

Silt.

528. Do these large water-holes silt up? In some districts where mining is carried on in the upper part of the creeks, the water-holes have filled up.

Estimate of irrigation with Gunbower scheme.

529. Could you give me a rough estimate of the probable cost, if a system of irrigation were carried out, in connection with the Gunbower scheme? No; I have not yet made a proper estimate; I have it in hand. I made a rough estimate, which will be found among the papers coming to hand. (*Appendix D 8.*)

530. *Mr. Townsend.*] You spoke just now of the inhabitants being in favour of substituting a scheme of irrigation: where would you expect to get the water from? From the Murray and Loddon.

Irrigation by gravitation from the Murray and Loddon.

531. By pumping or by gravitation? By gravitation; but I think they would also have to pump, because the water does not come down early enough. They want the water in May for irrigation, and the Loddon is a very uncertain river, but it could command also the upper part, if the volume was sufficient. The Loddon is diverted at Bridgewater, and it might give a certain amount of supply to the whole of this scheme.

Discharge of Murray at Echuca.

532. *President.*] Do the observations made at Echuca enable us to know the annual discharge in proportion to the rainfall? No, not yet. There will be data for that by-and-bye; but the discharge has not yet been measured at the different stations on the river; when that is done we can get at a correct average of the quantity discharged. The only measurement we made on the Murray is as to the minimum discharge at Koondrook in the summer of 1881–82, which was dry: it amounted to 50,000 cubic feet per minute.

Discharge at Koondrook.

533. What rainfall would that represent over the river? I cannot say. It might not have rained for two or three months before that.

Dams carried away by floods.

534. How are the earth dams affected by sudden floods? They are frequently carried away. The old squatters' dams were all liable to be carried away occasionally. That was only because they were not provided with proper by-washes.

535. Are they provided with waste weirs? No. Those taken over by the Trust are, however, so provided, or will be.

536. In consequence of not being properly supplied with them the dams were carried away? Yes, or the river cut a channel round them.

537. Is the timber dam quite successful? Yes.

Inundation.

538. Are the creeks that have been mentioned in this scheme capable of carrying the fullest quantity of water in times of flood without inundation? No; in very heavy floods a great part of the country is under water.

539. Would more extensive head works impound a much larger volume of water? No.

Water lost through heavy floods.

540. Then the water that inundates a large part of the country in heavy floods is lost? Yes, it flows off again into the Murray. A good deal of water could be stored in the Kow Swamp.

Storing tanks.

541. Is it contemplated to make storing tanks? Yes, for stock purposes only. But it is intended also to retain some water in the Kow Swamp.

Plough furrows to fill tanks along old creeks.

542. In this and the other schemes you refer to, is it usual for the farmers resident in the neighbourhood to have the water in any way running to their tanks and dams that are off the water channels? Yes; a plough furrow is made to fill their tanks along the old creeks, and a good number of tanks are excavated in the beds of the creeks. They disappear in the flood season, being covered by the flood.

Farmer Garden.

543. There is some farmer living in this neighbourhood who has been carrying on irrigation to a large extent—do you know his name? Yes, his name is Garden; he writes to the *Australasian* occasionally about it. I think his farm is described in a series of papers called "Irrigation Experiments" in that paper.

544. *Mr. Townsend.*] Is it done by pumping or by gravitation? By pumping. He lifts the water 5 or 6 feet from one of the dams on these creeks.

Expense of preparing land for irrigation.

545. *President.*] Have you any idea of the expense of preparing the land in those cases where irrigation is carried on? Very little is done in this country, which is naturally extremely flat; the only expense is in making an embanked channel to the farm, and pumping into that. I do not know what the expense would be. They do not like to tell what it is; and when they do tell it the information is vague, as they may employ their own men and carts, &c.

Loddon scheme.

546. Is there any other water scheme in the plan before us? Yes, two others—the Loddon scheme, which is being carried out, and this Campaspe scheme, which is not being carried out.

547. At what point do you take water from the Loddon? At Bridgewater, by means of a concrete weir.

548. And open cutting? Yes, on the east side of the river for about 3 miles.

549. What size? I think it is nearly a 6-feet bottom.

Water let into Bullock Creek.

550. At what distance is that water cut off? We pass the water into the Bullock Creek, a natural water-course which flows to the Box Creek, a distance of about 50 miles. There is nothing done at this part of the Loddon scheme except the head sluice at Bridgewater and the cuttings which are in progress. There is another weir in course of construction at Kinypaniel.

Timber weir.

551. What description of weir? Timber.

Kinypaniel weir.

552. How far is that down the Loddon? About 28 miles. The Kinypaniel weir is intended to throw the water into the Kinypaniel Creek, which is an outlet in flood-time; it is to fill Lake Boort and other lakes. It is about 12 miles down.

553. Is there any place where the water is taken out? It is proposed to take it out about 4 miles higher up, on the east side of the Loddon.

Works in Kinypaniel Creek.

554. What works are there in the Kinypaniel Creek? None except the head sluice.

555. And the cuttings? There is a slight cutting at the head sluice, perhaps three-quarters of a mile, made by the squatters long ago, and enlarged by the Shire Council. The outlet in the eastern side is not begun yet. There is a natural outlet called the Serpentine Creek, flowing parallel with the Loddon, and the mouth of that has been deepened for a distance of 2 miles. There are the remains of a weir at Serpentine Creek which was washed away. Instead of making a new weir they deepened the cutting.

556. That creek is midway between the Kinypaniel weir and the Bridgewater weir? Yes.

Discharge of water from Loddon into Gunbower.

557. The water taken on the eastern side of the Loddon discharges into the Gunbower scheme? Yes, and eventually into Lake Charm.

558. Are there many works on these various channels? These are natural creeks on which there are old station dams repaired and furnished with weirs, and many tanks are excavated here and there.

559.

Mr. G. Gordon, C.E. 8 Aug., 1884.

559. What area of country is supplied by that scheme? 1,273 square miles.

560. At what cost? Up to the present the cost has been £37,000.

561. The cost then is about seven-eighths of a shilling per acre? Yes.

Area supplied. Cost.

562. In the three schemes referred to, the cost I find is only the actual expense up to the present time? That is all.

563. In each case a larger sum of money will have to be expended? Yes. In most cases they desire to spend more; in some cases the loans were not sufficient for the works; in other cases they wish to extend the works.

Conditions for filling private tanks.

564. *Mr. Franklin.*] Under what conditions are the channels made in these distributaries to fill private tanks? I do not think the Trust have made any regulations—in fact I believe that they are only now beginning to frame regulations.

565. There would be a system of gauging established to regulate the supply? I do not think they would sell the water by measure for stock watering; the people would be rated for the purpose of paying the interest on the loan. Then if they wished to sell an additional quantity of water, they would I suppose measure it in the tank.

Rate.

566. *President.*] Has any rate been made or levied in connection with this scheme? No; it is proposed.

567. *Mr. Townsend.*] Have you come to any conclusion as to the cost per mile or per acre for working of this scheme? No, but they will be small in proportion to the first outlay.

Distribution of water.

568. *Mr. Donkin.*] How is the water distributed in the 5,500 acres—is it by small drains or otherwise to the farms? They just open the bank and let it run out.

569. *President.*] With a spade? Yes.

570. *Mr. Donkin.*] There is no system of ploughed drains? No. I think some of them have taken that course, but all are working in their own way at present.

The Campaspe scheme.

571. *President.*] Referring to map No. 2, you have three schemes there indicated (*Appendix D 9*)? Yes. The Campaspe scheme is not being carried out.

572. Is it likely to be carried out shortly? I think not, from the fact of the people wishing to go into an irrigation scheme in the lower part of the district, the water to be got by pumping from the Murray. The Campaspe is too irregular a river to be depended on for irrigation.

573. It is proposed to take the water from the Campaspe River? Yes. It was proposed to carry a channel from above a weir on the river to the Pickaninny Creek.

574. It is abandoned in consequence of the opposition of the people below? Yes. They will not join in it because they want an irrigation scheme to include the north part from the Murray by pumping.

Pumping scheme.

575. That scheme is similar to the Gunbower scheme? It would be entirely a pumping scheme. There is no natural outlet from the Murray, and the water would have to be lifted 27 feet or more. Then the water would have to be carried in a canal running due west to the Pickaninny Creek.

576. That is not being carried out? An application has been made for a Trust to be formed, but there is some difficulty in reference to the money. The Government do not lend money for irrigation schemes.

Raising of money.

577. Then how is the money obtained for the Gunbower scheme? That is not an irrigation scheme, although it has been used for irrigation by people at their own cost.

The Echuca West Riding irrigation scheme.

578. That is called the Echuca West Riding irrigation scheme? Yes. It is a very favourable country for irrigation.

579. It is purely an irrigation scheme? Purely.

580. And the Government have not provided any means for that purpose? No.

581. I presume that they are not likely to do so? No, they say not.

Irrigation from wells.

582. *Mr. Franklin.*] Are there any special improvements for irrigation from wells in this area? I do not think there are any in this Trust. In the St. Arnaud Shire and the Lowan Shire Trusts they sank a good many, but not for irrigation.

583. At what depth do they find the water? From 130 to 200 feet.

Appliances for storing the water.

584. Have they any special appliances for storing the water? They use horse-whims, which pump it into tanks, from which it is delivered into carts. Some use windmills, and add a small excavated tank to take the surface water.

Brackish water.

585. *President.*] Is the water pumped for these wells good for irrigation purposes? They only pump from them for stock purposes; the water is slightly brackish.

586. Would it be destructive to vegetation? I do not think it would. Some wells are more brackish than others. Having to lift to that height I do not think that they could irrigate at a profit, nor would the well yield a sufficiently large flow of water.

Permanency of supply from wells.

587. *Mr. Franklin.*] Is there a large and permanent supply of water from those wells over that area? I have heard of only one well that has not turned out a success. It is said that they have been equal to present requirements.

Underground supply.

588. Does it appear to be a good underground supply? No, not in the Lowan Shire. The underground supply is uncertain. They get water in some parts of a district, and in a similar district they get none, or very little; they have got to the bed-rock without striking water at a depth of 450 feet. That was the case at Jaen.

Quality of water.

589. *Mr. Townsend.*] Do you see any marked difference in the quality of the water at different places? I do not think there is much difference. In some places they can get only brackish water; but the nearer the surface the better it is.

Lower Avoca scheme.

590. *President.*] What plans of other schemes have you here? There is the Lower Avoca scheme. (*Appendix D 10.*)

591. Where is the water taken from by this scheme? The principal object of the Trust is to store water in the river Avoca, which has been known to be three years without water in it. They have constructed a small weir at the town of Charlton.

592. What sort? A timber weir. They have constructed three more at intervals of about 8 miles down the river from Charlton. The Charlton weir is a very small one, only sufficient to hold up the water to pump from, and they supplied the town by pumping. Now they are going to bring in a supply from about two miles off by gravitation. Then where the Mosquito Creek leaves the Avoca they have regulated the flow a little, but there is no weir there. Lower down there is to be a weir, perhaps near the Mosquito Creek, to regulate the outlet and supply the Lalbat Creek, and the Back Creek, which is a very small

creek

creek at present, flowing parallel to the Avoca at a distance of 3 to 6 miles. Lalbat Creek leaves the Avoca and flows into Lake Lalbat. Three more weirs are proposed higher up above Charlton, but the present loan is exhausted, and it depends on the Trust getting a new loan whether they will carry this out or not. The other works of this Trust are chiefly surface tanks. Mr. G. Gordon, C.E. 8 Aug., 1884.

593. *Mr. Barton.*] Filled from the creek? No; by surface drainage. There are tanks all along the Lalbat, and no doubt there are some which are filled by it.

Rainfall.

594. *Mr. Townsend.*] Have you any record of the rainfall there? Not at the source.

595. Or about the locality at which the tanks will be made? It is about 16 inches I should think.

596. *Mr. Gipps.*] What was the object of the three weirs? To keep the water in the river. This country is absolutely dry in the summer, the little creeks only run in a heavy rain, and when the river comes down rapidly it falls in a couple of days.

597. Then they will make off-takes? No, that would require deep cuttings. They propose to make one off-take 4 miles above Charlton, to go to the east, and I doubt whether it will be a success. The ground does not hold well.

Source of the Avoca.

598. *Mr. Barton.*] Where does the Avoca take its rise? In the Pyrences, a part of the Dividing Range. It rises in a place called the Amphitheatre.

Area of its basin.

599. Have you any knowledge of the area of country it drains? It drains a comparatively small area. There is only an intermittent supply.

600. *Mr. Gipps.*] Would the natural features offer any advantage for conservation? No; there is a gap where a dam could be made, but there is no supply to fill it.

601. What are the objects of the whole scheme then? Simply to conserve water in the river and make tanks in favourable places.

Porous bed of river.

602. *Mr. Barton.*] Not for irrigation purposes? No, there is not sufficient water. The bed of the river is very porous. I think the water for some years will go away; but these weirs hold up the flood-water and encourage a deposit of silt, so that the gravel will be choked in the course of time.

Area supplied.

603. What area will this supply? It is difficult to estimate, because the tanks are dotted about irregularly. It will supply a length of 60 miles, by 6 miles in width, and other detached portions. They speak of diverting water at Koonoon to fill Watson's Lakes, but it would be very expensive, and is not likely to be carried out.

Cost.

604. What is the cost of this scheme as far as it has gone? £19,000. I can hardly estimate the cost per acre of supply, because it is difficult to say what you consider a supply.

Law regulations.

605. *Mr. Gipps.*] What is the regulation under which water is allowed to be taken from the tanks? They have no regulation.

606. Can any one take it off as they like? No; there will be a law question about that. They were to have had the control of the creeks, but that they cannot get, as it passes private land. But they will make regulations as to the drawing off of water; indeed most of the tanks will be made by the Trust themselves.

607. This is being carried out by a Trust then? Yes.

Raising of money for the scheme.

608. *Mr. Barton.*] Who found the £19,000 for this scheme? The Government gave the Trust a loan of £15,800 and a grant of £3,600. The grant was distributed among the Trusts in operation.

609. Is it not supplemented by the holders of land? They are supposed to pay a rate to meet the interest on the loan, and partly to go to a sinking fund.

610. *Mr. Donkin.*] Any Shire can make application to the Government for a loan to carry out a water scheme? If the scheme is approved and the applicants show that the parties can pay the interest on the money at a moderate rate.

Water Conservation Acts of 1881 and 1883.

611. As to Water Conservation Acts of 1881 and 1883, have they worked well? Not quite satisfactorily, yet I think the dissatisfaction is chiefly as to the working.

Rights to the banks of the creeks.

612. *Mr. Gipps.*] Do the owners of land on the banks of these creeks have any right to the banks of the creeks, or have the Government reserved the right? In some cases there has been a reserve along the banks of running rivers; but in old times the land was sold, and with it there was a right as far as the middle of the stream.

613. Then the Trust has purchased the land? Or got permission to use it where they constructed works—a perpetual easement from the landlord without purchase.

Rights to the bed of the stream.

614. Would that give a right to the bed of the stream? Yes, if they desired to construct works in the bed. It would depend on what they take it for.

615. *Mr. Donkin.*] I suppose most of the occupiers and owners fall in with the proposals? They are willing enough to do so, but are anxious to get compensation. Some of the works are delayed owing to exorbitant prices being asked.

Power of the Trust to appropriate.

616. *Mr. Gipps.*] How do they deal with the water then? In one case the works were stopped until satisfactory arrangements were made. The Trusts have power to take land, or the Board of Works can, the value being fixed by arbitration if the parties cannot agree. That part of the statute was incorporated in these Water Conservation Acts.

617. *Mr. Donkin.*] So far, the working appears to be that those people in the Trust area take as much water as they like without paying for it? They have not been asked to pay anything for it by the Trust; but the Government have reminded the Trust that the repayments should begin, but the Commissioners say that the work not being finished a rate cannot be levied.

Repayment of loans.

618. *Mr. Barton.*] Do you find these Trusts constituted as they are have worked well? Some of them work well, some not well; I think it depends to a great extent on the *personnel* of the Trusts.

Working of the Trusts.

619. *Mr. Donkin.*] Do you know what is the rainfall at the Amphitheatre at the head of the Avoca? No; I do not think there is a gauge at the Amphitheatre itself, but I am not sure.

Rainfall.

620. *Mr. Townsend.*] Is not that place near St. Arnaud's? Not far away.

621. *Mr. Donkin.*] Have the Government taken steps to obtain more definite information as to the rainfall? The Government have done a little, but the Astronomer gets returns from many private individuals. The Government have given permission for a systematic gauging of all the principal rivers being made.

Gauging of rivers.

622. But nothing has been done with regard to the rainfall except getting reports from private persons? Gauges are kept by many Government officers in addition to the private gauge.

Floods of the Avoca.

623. Speaking from your experience, do you think there is sufficient rainfall at the head of the Avoca to supply these channels for irrigation purposes? No, the floods last only a few days.

624. Not i fthe water were conserved or dammed at the heads? No. The water does not come down for several

Mr. G. Gordon, C.E. 8 Aug., 1884.

several years. There is no good supply for a large reservoir; but a moderate one may be made a short way below the Amphitheatre. There is little catchment. The Avoca River ends in Lake Bael Bael, and has been traced 6 miles further north.

Mallee country. 625. Do you know whether in the mallee country irrigation or clearing has been tried? They have tried clearing. It is intersected by many sand ridges, and it does not hold any water; no creeks run in the mallee or out of it.

Cost per acre. 626. What is about the cost per acre of this scheme? About 1s. 8d.; but there are other districts supplied with tanks dotted here and there which this Trust has the management of.

627. But taking the whole area in this county? I have taken 60 miles by 6 as area of country benefited by the works on the river. The chief works are for storing water in the bed of the river; the others are tanks and dams.

628. Are there many wells? Not many sunk by the Trust.

629. To what depth do they generally go? I do not think this Trust had sunk any. They have spent some money in boring.

Gravelly bed of Avoca. 630. You say that the bed of the Avoca is rather gravelly, but that there is a hope that it will be silted up so as to bind the gravel? Yes.

Soakage. 631. Do you think that much of the water escapes by soakage? Yes, because in a big flood the river up above Charlton is a very formidable-looking stream, but down towards the north end it is insignificant.

632. I suppose no survey has been made by boring to trace any underground current? The Railway Department made borings to find a place for a bridge and found gravel to a considerable depth, but I am not aware of any survey having been made to trace the drift or the underground soakage.

633. *President.*] Is there very much silt? Not much—I should like to see more.

Nature of silt 634. Of what nature is the silt? Clayey.

The Goulburn scheme. 635. There is another scheme? Yes, the Goulburn scheme, which is one of the most important. (*Appendix D 11.*)

636. Where is the water taken from? It was originally proposed to take water from the Goulburn, about 8 miles above Murchison, from above a weir, and to carry the channel in a westerly and northerly direction to the Campaspe.

637. Is that being carried out? Only part of it; the weir was found to be so difficult in construction and so expensive that they intend in the meantime to take water a few miles lower down by pumping it from the river.

Height of weir. 638. What was the intended height of the weir? About 40 feet.

639. Of concrete? No, timber. There would need to be concrete walls and puddle to cut off the drift underground, but the main structure would be of timber.

Channel from Waranga basin to Wanalta Creek. 640. Is the channel completed? It is in course of construction from Waranga basin to Wanalta Creek. It is continued thence to Cornella Creek and Lake Cooper, and is complete to that point. It is also very nearly completed, as a drainage line runs from the Waranga and Cornella Creeks, northwards, to the parish of Koyuga. The reason for taking up this point was, that there is a considerable natural drainage into that locality, and the water could be conserved and taken down the natural drainage channel pending the construction of the weir, which would occupy about four years. Tanks have been dug along the course of the channel. The intention, of course, is as shown to distribute the water all over the district. There has been a delay in carrying out the scheme, because when the application was sent in to carry out the Goulburn scheme of the Water Conservancy Board they wished to make the channels large enough to carry water for irrigation, and as the Government were not lending money for irrigation they were requested to reduce the channels. But at last they obtained permission to carry out their plan, if they could do it with the amount of loan applied for. Then they found a difficulty about the weir. I resolved on a temporary measure, with a pumping establishment at Murchison, to pump a supply for domestic and stock purposes, and also for a small amount of irrigation.

Natural drainage.

Channels for water for irrigation.

Pumping establishment at Murchison.

641. Are they doing that now? They are just beginning; the other work has been going on for more than a year.

Dimensions of canal. 642. What is the length of this canal? About 70 miles.

643. And what size? 4 feet 6 bottom width; slopes, 1 to 1.

644. *Mr. Townsend.*] Is that the outcome of what is known as Dodd's scheme? No.

Branches. 645. *President.*] Are not branches taken from the channel? It is proposed to take channels down the higher portion of the country, but it is not surveyed yet.

Area supplied. 646. What area of country is it proposed to supply with water? 800 square miles.

Cost. 647. What is the estimated cost? £143,000. There is no application for an additional loan for this.

648. What is that per acre? 5s. 7d.

Character of Waranga basin. 649. What is this Waranga basin? It is a natural depression, with a good deal of water, though it is not very deep. It is shallower towards the north end than in the middle. It is a natural hollow, and it is proposed, instead of carrying a channel round the contour, to flume it across, and perhaps to conserve the water for irrigation. That is fully described in the two reports on irrigation.

650. What kind of country is that? Agricultural.

651. Is it level? Very level. There are two lines of drainage which unite towards the north-west. There is a sort of ridge parallel to the Goulburn and Murray Rivers, where the channels are to be carried, and a drainage to the north-west.

Depth of the channel. 652. *Mr. Donkin.*] What is the depth of the channel? 3 feet. It is a very small channel, but it is more than sufficient to give a supply for domestic purposes, but not to give enough for irrigation, except to a very limited extent.

Incline. 653. *Mr. Gipps.*] What is the fall? In one place 9 inches, but generally about 1 foot per mile.

654. *Mr. Donkin.*] What would be the head of water if the weir was completed—with so slight a fall would not the evaporation be very great? The weir would give no more fall.

Movable weir. 655. *President.*] Do you think that a movable weir would be more suitable than a stationary weir? It is proposed to make the upper part, to the extent of 10 feet, movable.

656. I mean with regard to the foundation? It would be very difficult to do that, the banks being very steep mud banks.

Volume of water in the Goulburn. 657. There is a large volume of water coming down the Goulburn? Yes. The difficulties would be great, because you have to raise the water 40 feet.

658.

Mr. G. Gordon, C.E.
8 Aug., 1884.

658. You do not think that a movable weir would be suitable? No, except the top part of it.
659. *Mr. Donkin.*] I think you said it was 80 miles long? About 70.
660. Would the water reach here in summer-time? Yes. There is very little loss in the Coliban channel, which is of similar dimensions.
Loss of water in summer.
661. The evaporation would be very great in the summer months? The absolute quantity of evaporation would not be greater than if there were a more rapid current, but the percentage of loss would be greater.
Fall of river.
662. *Mr. Gipps.*] What is the fall of the river at this place? One foot per mile. That is one reason why we could not go higher up. By going 10 miles higher up we could probably get a better foundation, but the expense would be enormous. The channel would have to be carried through difficult country the same distance.
Height of banks.
663. Would there be no means of diverting the water lower down? The banks gradually lower from 40 feet at Murchison. The banks at the Murray are fully 35 feet, and the ridge already mentioned parallel to the river would be an obstruction.
664. *President.*] How far is Murchison below Seymour? 30 miles by rail.
The Broken River scheme.
665. You have also the Broken River scheme? Yes; but it has been very much mutilated. (*Appendix D 12.*)
666. Where is that water taken from? The original scheme proposed to take the water from a point 6 miles below Benalla.
667. By means of a weir? A weir and cuttings.
Weir of stakes, sand, and fascines.
668. What kind of weir? It was intended to be a weir of stakes, sand, and fascines, and to be very broad.
669. Where is the water taken from now? From a weir at a place called Pine Lodge, about 20 miles lower down. This formed part of the original scheme. About 20 miles above Shepparton there is a cutting of about 2½ miles in length.
Clay-puddle wall.
670. What kind of weir is that? There is a clay-puddle wall across the middle, and a long slope down stream pitched with stone laid over bed of fascines.
Dimension of cuttings.
671. I think the water is taken by means of cuttings? Yes, 2½ miles in length, with 6 or 8 feet bottom width.
672. What are the side slopes? 1½ to 1 to 6 feet in height, and 1 to 1 above that.
673. What is the depth? The greatest depth is about 8 or 10 feet.
Khull's Range Creek.
674. How far do you take that down? There is an old natural watercourse below that, which needs clearing out. It joins another called the Khull's Range Creek; then it joins Broken Creek, which is in two branches, and flows into the Murray near Barmah. There are a great many dams on all the creeks, some of which need regulating, and some have been regulated by means of the addition of weirs and sluices.
Main channel.
675. Is the water taken off from that channel anywhere? No; there is only one main channel yet. They did intend to carry it off, but they have come to a stop, the Shire being separated into two; I think they are doing nothing except repairs to the weir at Pine Lodge, and constructing another at Barwo.
676. That scheme then is under two Shires? No; it was under only one, the Shepparton Shire—which is now divided into two, Shepparton and Shepparton South—and no determination has been arrived at as to the Trust. I have found that a channel taken from the Murray at Koonoomoo could be brought to irrigate a large tract of country; but that is not contemplated yet, and there is no proposal to do it. I was asked to find out whether it was practicable or not.
Distance from Pine Lodge to Barmah.
677. What length is it between Pine Lodge and Barmah? About 55 miles.
678. What is the approximate area of country it supplies? It can hardly be said as yet to supply beyond the parish of Mundoona; but when the creek is improved it will supply an area of 300 square miles.
Area supplied.
679. What area of country will that comprise? 300 square miles.
Cost.
680. Have you any idea of the cost? I do not know what they have spent, but a good deal more will be required. I think they have expended about £20,000.
681. What do you estimate it will cost to carry it to Barmah? About £30,000, probably, to complete that part of the scheme.
682. That would be about 3s. 0½d. per acre? Yes; that is taking it 6 miles across; but it was intended to supply the whole country that could be commanded.
683. That is not carried out? There was a talk about the union of the west half of the Yarrawonga Shire with the Shepparton Trust.
Irrigation of country above Benalla.
684. *Mr. Townsend.*] Have you examined the country above Benalla? This part may be irrigated by diverting the Devil's River, which is a wide, clear stream, into the Broken River.
685. You would bring it across by Mansfield? Yes. We are going to make a rough estimate of it. It would irrigate a large extent of country.
Summer supply of Broken River
686. *Mr. Gipps.*] What is the mean summer supply of the Broken River? It stops generally in summer.
687. How would you supply the canals? There are tanks to fill, and dams at intervals along the creeks, generally with a tank in the bed of the creek above them.
688. Would they throw back much water? Yes; there is one which would throw the water back 4 miles into a 6 feet depth.
689. The 6 feet would be only at the sill of the weir? Yes.
690. It would get shallower? But the channel could be cleared out.
691. Would not the tanks silt up? There is not much silt in these rivers.
Velocity of rivers.
692. *President.*] The rivers are not rapid there? No, they are sluggish.
Water storage in Victoria.
693. Then in Victoria you have no extensive scheme of water storage, only to distribute? It is mainly distribution, and storage in small tanks.
694. You have no extensive scheme to impound and conserve the water for distribution in the summer? No; it was not intended by these schemes, which were for domestic and stock supply, and if practicable, for irrigation.
Supply from Broken River.
Devil's River.
695. Is it practicable in this scheme? The Broken River in this scheme would not give a sufficient supply. The Devil's River might be brought into this river. The Broken River stops in the summer, but the Devil's River might be brought into it. It is a permanent river just like a good trout stream, with shingle in the bed.
696. *Mr. Donkin.*] Are the dams constructed by the Trust? Some were constructed by the Government, some by the Trust, and some are by private persons.
Overshot dams.
697. Are they overshot? Those made by the Government and the Trust are overshot.

Mr. G. Gordon, C.E.
8 Aug., 1884.

698. You have no plans? I have no plans of the weirs, except of the one at Dooen. All the weirs have given a little trouble as yet. I will let you have some sketches of those which have been successful. (*Appendix D 13.*) The Avoca River was the worst for trouble in construction. We have had considerable trouble with most of them, especially with that one on Wimmera at Glenorchy.

Plans of weirs.

Internal Trusts.

699. *President.*] Is there any other scheme? No, I think this is the last. There are internal Trust schemes for preserving water locally, but those I have mentioned are all the schemes proposed to be taken up by the Board.

700. How are these internal Trusts formed? By borrowing money and getting powers like those of the other Trusts.

701. How are the internal Trusts constituted—are they included in any way in the other Trusts? Take for example the Lowan Trust: a part of the Shire is made into a Trust District; they borrow a certain sum of money, and with it construct tanks and dig wells; then it is proposed to rate the people separately from the Shire rate.

702. But they have nothing to do with the schemes you have mentioned? Not with the rivers.

703. Nor with the water? In one case St. Arnaud's Trust joins the Avoca Trust, and they propose to make one or two weirs on the Avoca, but their principal works are tanks.

704. Are the members nominated or elected? When two or three Shires join, the members are elected from the Shire Councils of each Shire included, but one member is nominated by the Government. Mr. Black and I recommended that the Government nominee should be an officer of some standing in the Service, similar to that of a Police Magistrate; but they did not care about that, and nominated any one who was available in the district, and he has no important status. We thought he ought to be the Chairman, so as to keep the operations of the Trust within the Acts.

705. Do I understand that these are local Trusts having the management of the water supply inside the larger Trusts? No, not inside the larger Trusts; they are separate areas, and they have power to rate in their respective areas.

706. Suppose we have a large scheme such as you have described, and rate for the general distribution of water according to that scheme, could a small Trust have a distinct area in the centre of that scheme? No, it must be outside.

707. The internal Trusts have no effect whatever inside the other schemes? No, they are only internal as being confined to one Shire.

708. It is a distinct kind of class of Trusts from the larger ones? It has exactly the same power, but a slightly different constitution. For instance, the Lowan Shire is a pretty large Trust; they cannot divert water from the river. The St. Arnaud Shire Trust is comprised in the Shire and adjoins the Avoca, and they intend to make some works on that river, but the principal works are away from the river. These are both internal Trusts. Then, on the other hand, the Loddon Trust comprises parts of three Shires, and these Shires send two members each to the Commission.

709. These deal with underground water supply, and not a diversion of water from rivers? They can do both; they make surface tanks and so on.

Control over Trusts.

710. *Mr. Gipps.*] To what control are the Trusts subjected? The general designs and plans have to be approved by the Government.

711. Therefore no Trust could take advantage of its position in a higher part of the river? The Government look after that. It was part of our work to arrange the schemes so that by making a notch in the weir level with the sill of the outlet there might be a rough automatic distribution of the water.

Union of several Trusts.

712. *Mr. Townsend.*] Do you think it possible, in the initiation of a large national scheme for water supply and irrigation, to have smaller schemes interfering with it? If the larger scheme were promoted by anybody, it would be by the inhabitants of the districts where these Trusts are situated, and they would probably be absorbed in it. The Act provides for the union of several Trusts.

713. Suppose a number of these Trusts had established reservoirs at the head of a river where the main storage would have to be made, would they not have to be bought out? Yes. If an irrigation system is formed within one of these Trust areas, the Governor in Council is to decide which works of the original Trust they shall take over.

Examination of Darling River.

714. *President.*] In reference to the Darling River, you took a survey? I made an examination, but made no survey. I was furnished with the longitudinal section and plan, and made an examination from Wilcannia downwards to Wentworth, but I did not follow the whole course of the river below Menindie, but examined it here and there.

Locking of the Darling for navigation.

715. For what purpose was the examination made? For the purpose of a Navigation Company, with a view to locking the river Darling so as to provide for navigation up to Wilcannia. (*Appendix D 14.*)

716. In that examination did you come to the conclusion that it would be possible so to lock the Darling River that the water could be distributed over the plains? I did not give any special attention to that subject at the time. My only consideration was as to the navigation, but from what I saw of the country I think the water could be sent back in large quantities. The weirs used in the navigation could be raised to the level of the outlets, but it would be at a great expense. (*Appendix D 15.*)

717. Is the country similar to that about Gunbower? It is not like the Gunbower scheme; it is more like the country on the Goulburn or Murray Rivers. The Gunbower scheme is intersected by different creeks.

718. Are there many ana-branches of the Darling? There is a good number, but I do not know the number.

Supply from the Darling.

719. Is it your opinion that a scheme similar to those carried on on the Murray and Loddon from the waters of these rivers could be carried out from the Darling? Yes, but I think it would be more expensive, on account of the weirs requiring to be higher.

720. Did you notice whether the banks of the river were higher near the river than further up on the plains? I did not notice it, but I am pretty sure they must be, as it is the case in all rivers having periodical floods. When the river overflows the heavier particles are deposited first, so that the thicker deposit is near the banks.

Fall of the Darling.

721. What is the fall of the Darling? 3 inches in the mile.

Velocity.

722. Almost nothing? It is enough to give a good current when the river is in flood, but there are times when it would not be above half a mile an hour.

Longitudinal section of the Darling.

723. You produce a longitudinal section of the Darling River? Yes. (*Appendix D 16.*) The black line is the

the longitudinal section of the bed of the river. The blue or dotted line indicates the flood-levels as observed at different places and noted in the survey, but they evidently refer to different floods or different stages of a flood. Mr. G. Gordon, C.E. 8 Aug., 1884.

724. What length is this section? 368 miles.

725. How do you account for the indentations in the bottom? I do not know how the deep holes originated. The Murray is full of these deep holes, some of them 20 or 30 feet deep. Where there is a straight line, it indicates that there is very little variation in the bottom. Indentations in the river-bed.

726. What is the nature of the bottom? Sometimes sand and sometimes a kind of limestone—not rock, but a concretional sort of limestone or hard gravel. There is also a hard clayey substance in some places, and rock occurs in others; for instance, at Wilcannia and about 20 miles lower down. At another place lower down there is a bed rock which would be a good place for a weir if it were otherwise suitable. Nature of bottom.

727. Was the Darling very high when you went down? No; I went down in September, 1882, low-water, in a boat drawing 2 or 2½ feet of water, and the river was nowhere dry, although the boat was aground a great part of the time. Height of the river.

728. Would the weirs be very expensive which would have to be put across the river to divert any portion of the water? They would, to make them high enough to divert the water, and if the river were to be made navigable, it would increase the expense of the locking also. Cost of weirs across the Darling.

729. In constructing the weirs, what class would you construct as most serviceable? Where there was a good bed I would have a fixed weir half way across, a movable weir for the rest of the distance, with a lock built in concrete or stone at the bank of the river. System of weirs.

730. Would the same weir do for diverting the water? It would be cheaper for that purpose to have a timber weir, as we have in Victoria, but where the bottom is hard I would have a concrete weir for navigation.

731. Then you know nothing further of the Darling than you have stated? That is all I know.

732. You know nothing of the wells in that country? No.

733. You never travelled out from the river? No.

734. Do you know anything of the wells in the north-east part of Victoria? Only in a general way. I know one case where they went 460 feet deep and came on a bed of rock without water. That was in the parish of Laen. They met with very wet sand and pipeclay, and what water there was was in the sand, it was very salt, but they had no flow of water. (*Appendix D 17.*) Wells in the north-east of Victoria.

735. Do you know of any place where they had a flow of water where they came upon what was apparently old river-beds? They came upon water bearing drifts in many cases. There was one in which there was a distinct current in the bottom of the well, where it sank into drift, and it was sufficient to carry the bucket across the well, as I was informed. I did not see it. Water-bearing drifts.

736. What depth was that? Not very deep. I have no information on that point at present.

737. *Mr. Barton.*] Can you give us any idea of the average width of the Darling? It is from 180 to about 200 feet at low-water level; that is the bottom width, and the slopes are from 1½ to 1 to 3 to 1. Average width of the Darling.

738. What would be the height of the banks on an average? About 30 feet. Height of banks.

739. Then is it your opinion, considering the friable nature of the soil, that it is possible to dam that river sufficiently to irrigate the surrounding country at a cost likely to make it a commercial success? I do not think it would pay to irrigate from that river, the supply being so uncertain, but it may do very well to supply the back country for stock watering. Possibility of damming the Darling for irrigation purposes.

740. Not for irrigating? No. The diagrams of Mr. Russell show that the river flows only two months in some years. The quantity brought down in these two months is so small that it would require a very great expenditure to store and distribute it. The Darling is quite different from the Murray and Murrumbidgee which are extremely regular.

741. You do not know anything about the river above Wilcannia? No, I have not been higher up.

742. *Mr. Donkin.*] If the river were locked at Wilcannia for navigation, to what height do you think it would bring the permanent water? I think to a height of 6 feet above summer level. Probable effects at Wilcannia by locking the river.

743. Do you not think a greater depth could be obtained? It would be much more expensive.

744. But it would give a greater supply for the back country? What was taken would have to be in flood-time. It would increase the cost of navigation if locks were made high enough to throw the water into the back country, or it could be done by one of the movable timber weirs without a lock.

745. Do you think it possible to lock the Darling permanently to a height of above 6 feet, so that a larger body of water would be available to distribute over the back country by means of off-takes or channels? I think it would be more advisable to keep the navigation locks at the 6-feet level and put in special weirs to divert the water into the back country. There would have to be a great many locks for navigation where there would be no chance of sending the water into the back country, and it would be a useless expenditure to make them all of that height. It is quite possible that it might be cheaper to put in some places higher locks for diverting the water, keeping to the 6-feet height for navigation.

746. Would a weir of wooden construction stand? Yes I am sure it would. Wooden weir.

747. *President.*] If a navigation scheme for the Darling were agreed to, would it be possible to combine with it the distribution of water? Yes, keeping them to a certain extent distinct. I think there would have to be special works for navigation and special works for irrigation. Navigation with irrigation scheme combined.

748. Would the weirs serve both purposes? In some cases they might possibly be made to do so.

749. So that you would have to use extra weirs? Yes. The extra expense would be in the locks, and that could be got rid of partly, in some cases, by cuttings through the narrow necks that separate two points.

750. *Mr. Donkin.*] In any case there would be a very great waste of flood-water? Yes, I do not think there would be space with lakes to impound it, but the effect of locking the Darling would be to impound a considerable quantity of water. Waste of flood-water.

751. *Mr. Murray.*] Did you find the banks of the Darling much higher than the back country? I have not travelled across or taken levels.

752. Would it be possible by cutting a canal through the bank to divert the water into the ana-branches? No, the ana-branches seem to have their beds half-way up the bank, and I should think they rise several feet after that. They are flood outlets. Ana-branches.

753. *Mr. Townsend.*] Do you think there would be any great expense in securing the wings of the weirs against the action of floods? I think not, if you selected a good site. Securing the wings of the weirs.

Mr. G. Gordon, C.E. 8 Aug., 1884.

754. Did you examine the rocky part of the channel below Wilcannia? Yes.

755. What rock is it? I could not make out what it was—it was very hard.

Navigation: probable passenger traffic and freight.

756. *Mr. Gipps.*] Suppose the Darling could be made navigable, what would be the value of the passenger traffic and freight, and what percentage would they return on cost of works? I think I made out that the return would be about 10 per cent., but I have not my report by me to refer to. It was my opinion that it would not pay an outside Company to take it up at present, but would pay the people who were proprietors of land and otherwise interested in that part of the country.

Returns from navigation and irrigation.

757. As a general question, considering the annual charge upon the outlay, do you think it would be better applied to navigation than to irrigation? I am not prepared to say. I don't think it would be wise to spend large amounts in making provision for irrigation.

758. Suppose that in the upper part of the river sufficient water were preserved for a regular supply? I do not think it would be remunerative. The cheapest storage we could make is that at Warang; but that required a very expensive channel from the river to fill it, because it is not on the river.

759. *Mr. Donkin.*] What price was the cheapest? £17 5s. 11d. per million cubic feet.

Quantity of water for each lock.

760. *Mr. Gipps.*] What quantity of water do you consider it necessary to provide for each lock? I am not certain. I do not like to answer such questions from memory. Generally the locks are 6 feet lift, some 8, some 5½; they differ in lift.

761. You did not calculate the exact quantity of water for each lock? Yes; I took an average, but I do not come prepared with it.

762. It would be a considerable quantity? Yes.

763. The higher the weirs the less would be the quantity of water required to lock? Yes, because there would be fewer locks. On the other hand, the displacement of the vessel in the smaller lock would have a greater ratio to the contents of the lock.

Hydraulic power.

764. Have you applied power to any of these Victorian schemes? At Malmesbury there has been put up a turbine, and the person who put it up was allowed to work it as long as there was surplus water.

765. *Mr. Barton.*] For what purpose did he use the turbine? For sawing bluestone.

766. *Mr. Gipps.*] What horse power did he use? I do not know; it was about 3 feet culvert for the water and about 10 feet fall.

Position of locks.

767. *Mr. Donkin.*] On account of the Darling being a very tortuous river, would that be a disadvantage? You would have to choose a place for the locks, so as to enable a vessel to have a free course in and out.

768. From Wentworth to Wilcannia would the tortuosity give about double its length in a straight line? About two and a half times, speaking from memory.

769. *Mr. Gipps.*] In the treatment of the Darling, which do you think it would be most beneficial to provide for navigation or irrigation? For navigation, I think. You would never get thorough irrigation there; I do not think there is water enough in most years.

770. The lowest average I think is 170 cubic feet per second according to present records? You cannot take the average to be of any use.

Waranga basin.

771. *Mr. Donkin.*] What depth is the Waranga basin? About 6 or 8 feet. But that is not one of the ordinary marshes that occur in the Colonies; it is a very singular depression, more like Lake Charm.

Lakes.

772. Most of the inland lakes in New South Wales are simply swamps? I believe so. Those in Victoria are generally below the level, and could not be used for storage reservoirs.

773. *Mr. Townsend.*] In the case of two neighbouring lakes, is not Lake Camperdown considerably above the other? The lakes are at Basin Banks, near Camperdown. I think the difference of level is about 100 feet.

774. And one is salt and the other fresh? Yes; one salt and the other brackish, and there is fresh water between them.

Purpose of locking the Darling.

775. You say you do not think it would be a commercial success to lock the Darling for irrigation, but you think it would be for the distribution of water? I think so.

776. Do you think the bank would hold there for weirs? There are plenty of good places more favourable than those found on the Avoca.

Depth required for navigation.

777. *Mr. Gipps.*] What depth of water would be required to keep up navigation throughout the year? A minimum of 6 feet at the upper end of the pond. It would be just 6 feet on the lower sill. It would be level to the next lock, and there may be places between them 30 feet deep.

Distance between locks.

778. *Mr. Donkin.*] What number of miles apart would the locks be? They would average 25 miles apart.

779. In your visit to the Darling did you go simply to the river and back again? I went from Hay to Wilcannia, and came down the river to Wentworth.

Watercourses between Hay and Wilcannia.

780. From Hay to Wilcannia you crossed no watercourses whatever? Yes, I think we crossed some watercourse.

Catchment area.

781. Did you notice any catchment area from Hay to the Darling? No, I did not. There is no catchment there.

782. In your opinion the Darling is not fed by the rainfall on the surrounding country? No, I believe it is not.

783. Could the water from the Darling be diverted so as to supply the stock of the country to the south-east of Wilcannia? I think probably it could.

Increase of value of land through irrigation.

784. *Mr. Gipps.*] To what extent does irrigation in Victoria increase the value of the land? There has not been sufficient time to ascertain what increase of value it confers, but land would very soon be raised to three times its previous value.

785. You were connected with the Madras water-works? Yes; the undertaking of the Company with which I was connected was transferred to the Government.

786. *Mr. M'Mordie.*] It was one of the most successful schemes in India financially? No, the Godavery is the most successful one, and the Cavery is a good one.

Diversion of water from Toongabuddra.

787. What works were carried on by the Company with which you were connected? The diversion of the water from the Toongabuddra down the valley of the Kondana to the Penwar.

788. How was the water elevated from the river—by a weir? By a weir, including a small island in the river; the weir was a mile long. Then there was a channel or cutting for 3 miles, 250 feet wide, and about 8 feet deep. Then it came out on the slope, and was carried along that for 60 or 70 miles, giving off irrigation-channels as it went on.

Mr. G. Gordon, C.E. 8 Aug., 1884.

789. Was it not found practicable there to build masonry dams on sandy beds? It is quite common. On the Penwar we built a dam on a sandy bed on brick wells of about 6 or 8 feet depth, but the weir on the Toongabeddra was built on the rock.

Cost.

790. Do you remember the cost of the irrigation works per acre of the land irrigated? No, I cannot. The land included in the scheme was, I think, 400,000 acres, and the cost was £1,000,000. It was purchased by the Government about two years ago.

791. At that cost it was expected that the financial results would be satisfactory and pay for the outlay? Yes, they would have been.

Tank irrigation at Madras.

792. About the tank irrigation at Madras, can you give us any information? The irrigation below most of the tanks is limited in extent, considering the quantity of land taken up by the tank itself. There is sometimes a less area cultivated than that of the tank itself.

Cost of labour in India and in Victoria.

793. *Mr. Murray.*] It would be difficult to compare our system with the Indian system, on account of the greater cost of labour in this country? Yes. I have taken out the cost of one of the latest Indian schemes and reduced it to the Victorian cost.

794. The cost of dams I suppose is about four times as much in Victoria as in India? About five to one. In India the excavation of earthworks is 2d. a yard or less.

795. The irrigation is applied mostly to rice-growing? Yes, and sorghum and other crops in some districts.

796. *Mr. Townsend.*] Is there a large amount of wheat grown? Not in Madras, but in other parts there is.

797. *Mr. M'Mordie.*] There are some large tanks in Madras that irrigate large areas as compared with their own area? Some of the higher tanks do, but the larger number are small shallow tanks, on the east coast especially, and also in Mysore. Every drop of water falling on the east coast is stopped and utilized for irrigation. They would sacrifice one-half the land to irrigate the other half.

Country near Wilcannia.

798. *Mr. Donkin.*] In your journey from Victoria to Wilcannia were you impressed with the richness of the land on this side as compared with that in Victoria? No; Wilcannia is a barren-looking place; there is a good deal of sand there.

799. The Colony of Victoria as a whole is better fitted for agriculture, the land is richer—at least there is more of it fitted for cultivation, the rainfall greater, and I should like to know whether in your opinion you think irrigation will be a financial success? I think so; I think it can be carried out at £5 or £6 an acre for the original cost of the works, and it will pay at that.

800. *Mr. Barton.*] That is, 5s. or 6s. per acre per annum? A few extra bushels per acre per annum would pay that.

Advisableness of irrigating country of the Darling.

801. *Mr. Donkin.*] Do you think it would pay to irrigate the country on the banks of the Darling if it could be irrigated at an expense of £5 or £6 per acre? I think it would if done in small patches near stations to feed stock, if it could be done at that price; but to irrigate pasture requires much more water, and would cost more than I have stated.

802. Did you remark the Lachlan River at Booligal? No, we reached there at night. It is not very deep there.

803. You did not go above Wilcannia, and do not know the river system at the heads of the Darling? No, I never saw the country.

Catchment area of the Darling. Evaporation.

804. There is a very large catchment area, but the country is level, and a large quantity of the water never reaches the Darling? So I believe; that is the case with many rivers in Victoria. The water after heavy rains is left in shallow pools and sinks into the ground a few inches only in some places, and is evaporated.

Both means of water conservation.

805. *Mr. Gipps.*] What course would you suggest to the Commission in order to arrive at the best means of conserving water, or developing a plan for that purpose, from the heads of the different rivers? I think I should have the river systems examined, not surveyed, to ascertain the probable feasibility of diverting water into storage tanks for whatever purpose it was intended to use it. Some flying surveys could be made to see how far the diverted water could be carried, taking each river system separately. That is the way we did it in Victoria, and it answered very well, although I do not say that it would do equally well here. I think a good deal of water could be intercepted to carry to the westward.

806. *Mr. Donkin.*] The whole country is nearly level, with a fall of scarcely a foot to the mile, and there would be a difficulty in carrying out any plan by gravitation? You can do a great deal with 1 foot in a mile. Our rivers at the mouth generally have only about 3 inches. If you get depth you can get a good current at 6 inches in the mile.

Size of tanks in Victoria.

807. What is the size of the tanks used in Victoria for conserving and confining water? The largest, the Yan Yean, covers about 1,300 acres, and that at Malmesbury is of about the same extent but deeper. (*Appendix D 18.*)

Quantity of water per acre and per annum for irrigation.

808. It is something like that scheme for storage that you recommend for adoption here? Storage for irrigation must be on a large scale, but at the same cost as these works it would hardly pay. Taking different kinds of irrigation, it takes about 75,000 cubic feet of water to the acre per annum, or at the average cost about £20 per acre, according to the cost of the Victorian storages.

809. That is allowing for loss by evaporation? And the difference in the kinds of crops.

Traces of old river beds.

810. You had no survey in Victoria to trace out any of the old river beds underground? No; borings for water were made by the Mines Department, but I do not know anything about the results, and I do not think they are yet published.

811. *Mr. Murray.*] I suppose there are a number of local Boards in each system in Victoria? Sometimes a Shire has a Trust to itself, sometimes two or three Shires have one Trust, each sending one or more representatives to the Trust Board, and one member is appointed by the Government to the Board.

Size of shires in Victoria.

812. What is a convenient size for a Shire? There are all sizes in Victoria. Swan Hill is the largest in that part of Victoria.

Irrigation of country from Tocumwah to the Wakool River.

813. If a water scheme can be so well supplied there, could it not be better applied to the Edwards River and the country round Deniliquin? That district is in New South Wales. From near Tocumwah to the Wakool River a large extent of country could be irrigated by gravitation, and the water could be taken off the Murray at a trifling cost. The Murray rises there about 13 or 14 feet, as against 35 feet at Echuca, and I think the valley of the Edwards, and the Wakool, admirably suited to an irrigation scheme.

814. *Mr. Donkin.*] You have heard of the Yanko cutting? No.

Quantity of rainfall flowing off the surface.

815. *President.*] Has anything been done in Victoria to find out in hilly country the permeability of the rock? I gauged it at Sandhurst, and the quantity of water flowing off the surface was one-sixth of the rainfall which fell on it. That was on rocky ground on the gold-field.

816.

Mr. G. Gordon, C.E. 8 Aug., 1884.

816. Would the rest get away through the strata, or be absorbed principally by evaporation? It must get away; it flows quickly off the ground. It does not lie about in pools there, so that very little was lost by evaporation, it was mostly absorbed.

Soakage. Water losing itself through the bed of the rivers. Avoca.

817. You never applied any test to the rivers to find out whether the water gets away in the beds? We know without making special observations that this is the case with the Avoca. The comparative smallness of the river lower down makes it apparent. It cannot get away except through the bottom, which is quite loose.

818. *Mr. Townsend.*] Has any attempt been made to determine the age of the gravel in the Avoca—the series of drifts to which it belongs? I do not know.

THURSDAY 14 *AUGUST*, 1884.

Present:—

MR. BARTON, M.P.,	MR. MURRAY, M.P.,
MR. FRANKLIN, C.E.,	MR. M'MORDIE, C.E.,
MR. GIPPS, C.E.,	MR. TOWNSEND.

F. A. FRANKLIN, ESQ., C.E., IN THE CHAIR.

Henry Chamberlaine Russell, B.A., called in and further examined:—

H.C. Russell, B.A. 14 Aug., 1884.

819. *Chairman.*] There were some matters I believe, Mr. Russell, in reference to which the Commissioners wished to re-examine you? Something was said with reference to my further examination upon the subject of wells.

Wells.

820. Can you give us any further information in reference to that subject? I have obtained some information, and I have endeavoured to arrange it in a form convenient for reference by the Commission. I am afraid, however, that what I have been able to do is not sufficiently complete and systematic to serve the purpose of the Commission. The plan I have adopted has been to mark on the map which I produce (*Appendix D 1*) the position of the wells as to which I have information, together with the depth at which water was obtained. In cases where only salt water has been obtained I have written "Salt" against the number of the well on the map. The Commission will observe that nearly all the wells are clustered about

Well on the Wee Wattah Station.

the north-west portion of the Colony. The well marked No. 1 is on the Wee Wattah Station belonging to Messrs. Officer & Co. It is about 18 miles north of the Darling, and 80 miles from Wilcannia. Good water was found at a depth of 142 feet. The temperature of the water was 82°, and the supply was at the rate of 50 gallons per minute until the bore choked with sand.

821. *Mr. Gipps.*] Through what strata did the bore pass? I have been able to obtain that detail only in a very few cases. Five bores were put down in the Wee Wattah Station in the vicinity of an old mud-spring; water was obtained at depths varying from 134 to 142 feet, but all the bores were finally choked up by drift. The well marked No. 3 is on the *Gualla Station, about 60 miles from Wilcannia. I do not know the exact locality. Water was obtained by an artesian bore.

822. *Mr. Murray.*] Is the well near Cobar? I do not know. The well was reported by Mr. Gilliat.

Well near mud-spring.

823. *Chairman.*] What is the well which is marked No. 4 on the map? That is a well sunk on the Wee Wattah run, near a mud-spring. No. 5 is at a place called Mullyer, 14 miles north-east of Wee Wattah, and 24 miles back from the Darling. Four bores were put down close to an old spring. In one bore water was obtained at a depth of 49 feet. The supply was at the rate of 12 gallons per minute, and the temperature was 63°.

824. *Mr. Townsend.*] Have you any information as to what height the water rose? In some cases. For

Inexhaustible supply at Gnalta. Medlow well.

instance, on the Gnalta run water was found at a depth of 272 feet, and it rose to within 100 feet of the surface. The supply of water appears to be inexhaustible. At Medlow well—a native well,—near Farina, South Australia, water was found at a depth of 12 feet; at 17 feet there was a sand-drift. The supply was equal to 36 gallons per hour. At Goonery Station water was found at a depth of 122 feet, and the supply

Well at Goonery Station.

was at the rate of 1,000 gallons per hour. Near Goonery, about 51 miles west of Bourke, abundant water was found at 61 feet; it rose to within 21 feet of the surface. At 69 feet another supply was found; that rose to within 3 feet of the surface. At that point a great quantity of sand came up with the water.

Fossil bones.

At 34 feet in this well large quantities of fossil bones were found, and some very large teeth, &c., belonging to some extinct animal. There is on the same station another well giving a supply equal to 65 gallons per hour, water having been obtained at 76 feet. On the well being sunk 6 feet more through some granite

Water at Bingera. Water at Tolarno.

boulders the supply was increased to 1,000 gallons per hour. Water has been found at Bingera at a depth of 75 feet, and the water rose 6 feet in an hour and a half. At Tolarno, which is south of Wilcannia on the Darling, salt water is generally found at a depth of about 93 feet. On one occasion they had to sink to 135 feet before the water was found. The bore went through a sanddrift which was perfectly dry, the sand being as fine as flour. They got nothing but salt water. I have heard that a well has been sunk since, in which fresh water has been obtained, but by going through the salt; I have not particulars of it. Then

Dunlop Station.

on Dunlop Station a strong supply of fresh water, rising to within 90 feet of the surface, was obtained at a depth of 488 feet. That well is marked No. 13 on the map. I have also to report on a well at

Well at Mount Browne.

Mount Browne. That well is also marked on the map. All that I can ascertain about it is that it supplies sufficient water to keep an engine going night and day, and to water some 18,000 sheep. The supply of water is apparently inexhaustible. There is another well on Dunlop Station yielding an abundance

Rise of water on Dunlop Station.

of water at a depth of 573 feet. The water rose to within about 15 feet of the surface. The shaft for a depth of 300 feet is 6 feet × 3 feet, and it is then continued by a water auger. At 240 feet petrified wood, water-worn pebbles, dead fish, and marine shells were found. At 300 feet a tree 18 inches in diameter was

Fossils.

found; at 443 feet another tree was found; and at 500 feet, fossils. At 550 feet there were 5 feet of sand-

Sandstone rock.

stone rock. When the water was struck the auger dropped 2 inches into fine sand-drift. This well is 20 miles west of Mount Wilson, and is 80 miles west of Bourke. 825.

---

*NOTE (*on revision*):—The name of this Station, Gualla, though copied from a newspaper report is, I have little doubt, wrongly written, and should be Gnalta, in which case it would be the same as No. 27. No. 3 may be made from the following well record found since I gave my evidence:—"No. 3. Mr. Gaden had a well sunk on the Marra Creek, 15 miles back from the Darling, and at 100 feet got an abundant supply of water that seemed good enough for sheep, but when young sheep were sent to it most of them died in a few days, and the rest had to be removed."

H.C. Russell, B.A.

14 Aug., 1884.

825. *Mr. Townsend.*] What would be the height above the sea-level about there—from 350 to 370 feet I suppose? Yes.

Height above sea level.

826. *Mr. Murray.*] What borer was used? A tiffin borer, I believe. At Girilambone an abundant supply of fresh water was found at a depth of 155 feet. It rose 22 feet 6 inches in the bore. That well is marked No. 16 on the map. The well marked No. 17 is 11 miles from Forbes. An abundant supply of fresh water was found there at a depth of 136 feet. It is about 7 miles from the edge of the river, on the border of a large plain, and white sand rushed up with the water. There was a rise of 76 feet of water in a few minutes. Salt water was found at a depth of 100 feet, and fresh water 36 feet deeper. I have information of another well on St. Ann's, at Cooper's Creek, where water was found at a depth of 60 feet. In the case of another well in the same locality water was found at a depth of 90 feet. These wells are 320 miles north of Wilcannia. On the Urisino block water was found at 430 feet; it rose to within 100 feet of the surface. A whim was kept going for twenty-four hours, but made no effect whatever in the height of the water. Before reaching the water a limestone rock with fossils was met with. I do not know what the fossils were. The well is 150 miles north of Wilcannia. In Victoria, on the Avon Plains, water was found at a depth of 28 feet, giving a supply of 200 gallons per hour. I have particulars of another important well outside of the Colony—at Tarkanina, which is 60 miles north of Farina, in South Australia. Water was found at a depth of 1,220 feet—that is, 1,100 feet below the sea-level. It is good, and it rose 20 feet above the surface. Salt water was found at 800 feet.

Well supply at Girilambone.

Well on St. Ann's.

Water in Avon Plains (Victoria).

Well at Tarkanina (S. Aust.)

827. *Mr. Gipps.*] Were you able to obtain the strata? No, I have been unable to do so. I am aware that it is very important for your purpose that that information should be obtained, but in many of these cases it is quite impossible to ascertain it.

828. Do you know whether the supply of water in all of these wells has been permanent? I have not that information. I have some information with reference to the wells on the Kallora Run, of which Mr. Brown is the manager. The owners of the station, I think, are Messrs. Officer & Co. One or two wells have been sunk, and water has been obtained. I have had some correspondence with Mr. Brown upon the subject, and he has now and again mentioned these wells to me. I believe, however, that the Commission could obtain from him a more connected account than I can give. I would also suggest to the Commission that Mr. Gilliat, Inspector of Tanks, may be able to give them some important information with reference to wells. The well marked on the map No. 23 is at Walgett. Salt water is found at a depth of about 100 feet; it is only 50 yards from the river. A great number of wells have been put down in that part of the country, that is about 4 or 5 miles distant, with similar results—salt water has been invariably found. I think that more recently, however, fresh water has been obtained in the district. There is a sort of fine drift sand, something like that at Wilcannia.

Permanency of supply.

Well at Walgett.

Fine drift sand.

829. *Chairman.*] Have you the depth in all those cases in which salt water was obtained? In many of them—not in all.

Salt water.

830. I ask because in many cases salt water has been found in the Riverina plains; it has been shut out, and fresh water has been found underneath it? That is the case in the deep wells of which I have given you particulars. In South Australia they have found salt water at a depth of 800 feet; it was shut out, and they afterwards found a good supply of fresh water.

Salt water at a depth of 800 feet.

831. *Mr. Townsend.*] What we want to know is the elevation of the land above the sea-level? The only clue to that in the far west is the level of the river. The railway levels have run out to a certain point, but it was from the river level that I obtained the height at Bourke. I do not know that there is anything west of Bourke from which you can obtain the height of the land. In Gippsland in Victoria a well was sunk 62 feet, and the water rose within 10 feet of the surface.

Elevation of land above sea-level.

Well in Gippsland.

832. *Mr. Townsend.*] That is at Sale, is it not? That is one of the wells at Sale. In the case of the second well there the water was found at 231 feet. It is an overflowing artesian well, bringing up dead leaves, decayed wood, nodules of iron, &c. I think I mentioned it when I was last giving evidence before the Commission. The well marked 26 is at Zaen. Several heavy streams of water were cut, the bore going down 400 feet. A tree and some plum-stones were found at a depth of 250 feet from the surface. A drift was found 150 feet deeper, or 400 feet from the surface. That well is in the Wimmera district, between Wentworth and the sea.

Well in Wimmera district.

833. *Chairman.*] You have no information as to how the supply of water from the well has been kept up? I believe it still supplies the town with the demand made upon it. I do not know what the demand is. The well marked No. 27 is at Gnalta. The water was found at a depth of 127 feet, and it rose 50 feet in the well.

834. *Mr. Barton.*] Is the well at Girilambone a Government well? Yes, the water was found there in April, 1883. The man in charge of the auger said he would not go an inch deeper until he received orders from the Government. I have a memorandum of five wells sunk near Girilambone. They all found salt water, and when they got a stream of fresh water at Girilambone they stopped. This is why the man to whom I have referred said he would stop when he reached fresh water. At Parkes there is a well, at which water was found from 40 to 50 feet from the surface. The supply is described to me as a perfect sea of fresh water. In the same neighbourhood a well has been sunk with similar results. The well to which I refer is 10 miles south of the river. At Ardennes in the Wilcannia district, water has been found at 300 feet from the surface. It is of first-class quality. At Gilgoin, 16 miles from the Darling, water was found in a bog 28 feet from the surface. It was clear and on a sandy bottom. It rose to the surface, and was piped to troughs. The bog is called Cuddy's Spring. Two whole skeletons of large animals were cut and fossil teeth were dug up when the well was being sunk. At Collana, 450 miles from Adelaide, a splendid artesian well has been struck on Mr. Dutton's run, in a south-easterly direction from Lake Eyre. This was in July, 1879. At the Depôt Glen the well marked 32 on the map will be found. Water was discovered at 55 feet from the surface, and rose 6 feet in the shaft, and required horse power to keep it down, to enable the men to go on working. This is in the Albert district. On the Boorara or Boora run water was found at 40 feet in fine sand. It brought up with it many fine pieces of charcoal. The well marked No. 34 is a little north of Walgett. Fresh water was found in fine sand, at a depth of 80 feet. In this part of the country it seems uncertain how far they sink for fresh water when you have found salt. There is a valuable well in South Australia, St. Stephenson, 274 miles north of Adelaide. Water was found at a depth of 205 feet. The supply is decribed to me as a fine spring of fresh water. The Commission will notice a well at Brindingabba. It is near Hungerford, at the Paroo, 121 miles from Bourke, and 3 miles south of the Queensland border. Here two wells were sunk

H. C. Russell, B.A. 14 Aug., 1884.

sunk close to a dam between two hills. In the first no water was found, although it was sunk 130 feet; in the second water was found at 125 feet; the supply is very abundant, and rises to within 43 feet of the surface. When sinking this well, shells and lignite were found at 120 feet from the surface. I think the Commission will find great difficulty in obtaining the information they require with reference to some of these wells—people will not give it to you. A friend of mine at Hay endeavoured to obtain some detailed information for me, but as soon as it became known that it would be published, the persons to whom he applied refused to give it to him—they did not wish the information published.

835. *Mr. Murray.*] I suppose they are afraid of free selectors? I suppose so. It seems to me that the information I am able to give the Commission is very imperfect. Of course you want the sea-levels. You can get these from the Macquarie to the Bogan and Bourke from the railway levels.

Source of water in different wells.

836. *Mr. Townsend.*] Can you give us any information as to whether the water struck to the east of the Barrier Range is the same as that struck to the westward? No. As a rule there is no careful test of the water which is found. I have not heard of any analysis being made in South Australia, and it would be impossible to tell whether the water was the same.

837. But if you have a series of wells coming from and going to the Barrier Range, would not the depth of the water be a guide to you? In looking at the subject myself I have been very much fogged. You find in one place an abundant supply of water at a depth of 100 or 200 feet, and within a few miles you get a supply at a depth of 400 feet. That is evidently a different supply. The impression left on my mind from what I know of the subject is that a great many of the wells have been found in old river-beds. On the Goonery run, for instance, a moderate supply of water was obtained at a depth of 76 feet. The bore was taken through granite boulders 6 feet deeper, which certainly do not grow there, and a supply at a rate of 1,000 gallons an hour was obtained. A few miles from this, in another well, a tree was found at 300 feet from the surface, and an abundance of water at 443 feet. For a long time past I have felt that what was required was a map showing where the wells are, and the depth at which the water was obtained. I have thought on the subject for some time, but I have found that I could not get the information necessary to enable me to carry out my plan. The well marked No. 38 is at Winchelsea, in Victoria. Water was found at a depth of 488 feet; it is an artesian well, and the supply is equivalent to 300 to 400 gallons per hour. Well No. 39 is in the mallee scrub in South Australia. It goes to a depth of 112 feet. The Mulga gives a supply of 2,000 gallons per hour, and it is obtained below loose drift. This well is on country adjoining Cuthawarro Station, about 31° 55′ latitude, and 141° 50′ east longitude; at first it gave only 800 gallons per hour, but after two attempts the well was sunk below the loose drift, and the supply rose at once to 2,000 gallons per hour. Well No. 42 is near Bourke. Water was struck at 192 feet from the surface. You will see near that another well in which water was found at 61 feet. It is splendid fresh water, and it rose 40 feet in the bore-hole. I have not entered well No. 44 on the map. It does not bear very much on the question, except for the fact that Mr. Hall had a well upon the mountain, and one at Darrbrook, in which the water rose and fell simultaneously. I wrote for particulars, but did not get them. I now come to the wells to which I have referred as having been sunk by the contractors for the Nyngan and Bourke railway line. In one case, a bore was put down 76 feet, and salt water was obtained. They sunk to 121 feet, but no more water was found. The bore passed through quartz ore and hard clay. In the case of another bore sunk by the contractor, water was found at 76 feet, but it was also salt. The bore was continued to 250 feet, but no more water was found. In this case the bore passed through clay and sand. On the same railway line, a well was sunk 115 feet to salt water. The well was continued to 135 feet, but no more water was found. In another case on this line, a bore was sunk 70 feet, when salt water was found; at 142 feet, more salt water was found. The water rose 50 feet, when the work was abandoned. Water from the well is now being condensed. Another well was sunk to 150 feet, and no water of any kind was obtained. At a place called Snowtown, in South Australia, water was found at 166 feet. It rushed up 16 feet above the surface, bringing at first about a ton of sand. It yielded 200 gallons per hour of good water. At Cobar water was found at 627 feet, giving a supply of about 300 gallons a day. The well marked No. 52 is at Greenhills, on the Barcoo. Water is found in abundance in this locality, in wells about 90 feet deep, and the water is described to me as being as soft as rain-water. Not far from this point, on Darr River Downs, water is found at 80 feet. Mr. Marr, in a well at Narramine on the Macquarie, found petrified myall at a depth of 180 feet. Well No. 54 is on the Nondaro run; good water was found at a depth of 140 feet. The well is about half-way between Poolamba and Wonaminta. A number of wells have been sunk on Liverpool Plains; they average from 40 to 70 feet in depth, and water has been found in an old river drift. I have had special information with reference to the Wandoola, Liverpool Plains, well; that is the second well. Water was found in it at a depth of 159 feet. The first 100 feet of sinking was through red soil containing layers of gravel with fossil bones and teeth. Another well was sunk 60 feet deep on the same run; it has continued to overflow for the last fourteen or fifteen years. I do not know whether I mentioned, in connection with the wells at Dunlop's station, in which the water rose to within 10 feet of the surface, that at a depth of 300 feet a tree was found 18 inches in diameter, being in a horizontal position, with the branches to the west and the roots to the east. The tree was petrified, but it appeared to be like the trees which are now growing on the surface. 143 feet lower, another tree was found. Near Silverton water has been found at 240 feet from the surface. The water rose 72 feet in the well. I feel that the information which I have been able to obtain with reference to these wells is exceedingly imperfect. I have not the means to make a statement as comprehensive as I should like to make it. I have no information as to Riverina, but I know that water has been found there in many wells.

Number of Government wells.

838. *Chairman.*] How many of the wells you have named would be Government wells? Only about half a dozen of them. There is a well-sinker in the Riverina district who can give you some general information with reference to water found in that locality.

Difficulty in obtaining information.

839. *Mr. Murray.*] Do you not think that the altered condition of the land law will induce lessees to give more detailed information than they now appear willing to give with reference to the supply of water on their runs? I dare say that in many cases they would be induced to do so, but once a prejudice has been established it is hard to overcome it. Mr. Abbott collected a great deal of information with reference to the Liverpool Plains district, at my request, but he informed me that he had the greatest difficulty in obtaining what he wanted. In many cases particulars of wells were refused when he asked for them, and he was obliged to obtain it by riding about the district and making his own observations. There are one or two matters which have come to my knowledge since I was last examined, and which I

should

H. C. Russell, B.A.

14 Aug., 1884.

should like to mention to the Board. Mr. W. E. Abbott informs me that in September, 1880, he visited Dubbo, and the river was running 15 feet deep, and at a rate by careful estimation of from 4 to 5 miles per hour. The flood gradually fell, and at the end of three weeks he saw it again still running 4 feet deep and at the rate of 3 to 4 miles per hour. This water never reached the Darling, in fact scarcely reached the marshes or about 250 miles; yet if we take the least estimated velocity, 3 miles per hour, the water travelled past Dubbo 72 miles per day, or 1,440 miles in the twenty days. That is about enough to reach Wilcannia, and it only travelled 250 miles, or the distance it should have passed over in three and a half days. The average depth was 9 feet 6 inches passing Dubbo, and six times as much passed Dubbo as was found in the river lower down, so that in fact nearly all the water soaked away into the gravel beds in the Macquarie River. At the end of June, 1884, for three weeks the water ran past Dubbo with an average depth of 2 feet 6 inches, and a velocity of about 2 miles per hour. This water took three weeks to reach Gin Gin, 40 miles from Dubbo in a direct line. At 2 miles per hour it would go in a day 48 miles, and in three weeks or twenty-one days, 1,008 miles. This quantity of water therefore passed Dubbo. Now, even if the river course measures 96 miles from Dubbo to Gin Gin the water should have reached there in two days, but it took twenty-one days, so that ten times as much water passed Dubbo as reached Gin Gin. This gives some idea of the enormous quantity of water which gets away through the gravel beds in the river. I mentioned to the Commission before that, although the river was apparently dry at many places near Dubbo in March of this year, there was a current in the river-bed passing through the gravel. The deposit of gravel in the river now is enormous. 40 feet from the surface it extends all over the flats, and contains water. At the bridge trees were found in the old bed 85 feet below the present river-bed. These and other facts show that the deposit has been in progress for countless ages. There seems to me to be conclusive evidence that the water gets away in the Macquarie and other rivers by means of these old drifts, which act as drains to carry away the water, and so effectively that in a recent fresh lasting three weeks, five-sixths of the water ran underground at once. A gentleman who has resided at Dubbo for many years tells me it is a well-known fact that the river being low it required a very heavy rainfall before the water would run down the river.

Flood of Macquarie observed by Mr. W. E. Abbott in 1880.

Observations in 1884.

Depth of gravel in Macquarie river-bed.

840. *Chairman.*] Do you think it would be possible from local inquiries to discover the point at which this soakage commences? I doubt it. It would appear that the gravel extends right under the rivers, and in some cases under the flat lands, as in the flats about Dubbo and other places. The bed of the Castlereagh is at present about half filled up with river drift. There is a place parallel to it which I have already mentioned; it is called the "Monkey," and it is evidently an old bed of the river filled up with drift, and water can always be found in it at a comparatively shallow depth.

Extent of the gravel deposit.

841. *Mr. Murray.*] Are there any stations there for the observation of the river? There are none higher up than the point of navigation.

842. *Chairman.*] In India, where the rivers are wide and shallow, and where they are filled to an enormous depth with sand—the Ganges and the Jumna for instance—they succeed in diverting the water in enormous volumes to a safe holding-place behind the weir: we thought that if we could obtain the requisite information with reference to the Darling country, it would be well to intercept the water at certain points and divert it into the river again at a point where we know the bed to be solid? It would, I think, be requisite to make surveys and to have borings made to get that information.

843. *Mr. Gipps.*] Most of the rivers have rocky bars running across them? That is so in the case of the Darling.

Rocky bars in Darling and tributaries.

844. And almost all its tributaries? Yes; I know there are such rocky bars in the rivers. I was about to say that on the Coomoo Station, somewhere about the head of the Peel River, a great many little creeks run out of the hills and disappear into the ground as soon as they reach flat land. The same thing takes place in many parts of that country. I referred before to a communication which I received on this subject. I now produce it for the information of the Commission. (*Appendix E 2.*) It will be observed that the writer refers to the number of cases in which the same state of things may be found.

Creeks at the head of Peel River.

845. *Chairman.*] Has it been an established rule to register these flood-marks? I do not know whether it has; I think not. There was nothing of the sort at Dubbo when I made inquiries in March this year, but I have since learned that Mr. Samuels has made some records on the trees.

846. How many established registers have we in the Colony for the observation of the height of the floods, or ordinary river-levels? There are four on the Murray and three on the Murrumbidgee, and five on the Darling from Wentworth to Bourke.

River gauges in the Colony.

847. Do you not think it would be a great advantage to have established at all towns on the rivers these places for observation? They would give a very valuable record. I tis difficult to say, however, where it would be best to endeavour to obtain the information, unless you had surveys, or found some one who knew the localities.

848. From what Department do you obtain the most reliable information on this point? I think all the gauges have been established by Mr. Moriarty. I sent to Bourke the other day to ascertain whether there were any river records of past years, and the reply I received was that there were no records prior to 1879; that is when I began to publish them. The records had been purely official, and the people in the locality had no opportunity of keeping them. I do not think there is a continuous record of any rivers prior to 1879, except the records which I have already handed to the Commission. Records, however, have been kept at Moama and at Ki.

849. Have you any simple system of gauge which could be established generally? In most places the gauge is put upon the bridge in some fixed position, with the feet and inches marked on it.

850. Have you no self-registering gauges? I have for the tides, but as regards the rivers there is a difficulty, because a river may at any time rise 30 or 40 feet. The Hawkesbury rose 50 feet in one night, without a drop of rain falling in the district. This was the first flood they had.

Self-registering gauges.

851. *Mr. Murray.*] Would it not be a good plan to appoint district or staff surveyors—where there are such officers—to keep these records, and where these officers are not to be found, the police? Yes, it would be better to have some one who is accustomed to make records. The police, like telegraph operators, are movable. You may train a man to do the work, and immediately he becomes efficient he is sent somewhere else.

Appointment of person to keep records.

852. *Chairman.*] Would not the work come more properly within the province of the Clerk of Petty Sessions? Yes, I should think so—they could keep the record very well. My own impression is that it would be well to establish at selected places on the principal branches of the Darling—say the Bogan, Macquarie, Namoi, Barwon, and other rivers—gauges, from a careful observation of which you might be able to form some idea as to where the water goes.

853.

H. C. Russell, B.A. 14 Aug., 1884.

853. It might perhaps be well to request the Department of Roads to fix gauges on all the bridges, to find the nearest resident and ask him whether he would keep the record? Mr. Bennett offered to have a record kept in that way along the coast rivers, but it has not been done. It would involve the putting up of gauges at all the places, and that means the expenditure of a considerable sum of money.

854. My idea is that if we obtain your advice on the subject, we might make a recommendation for these gauges to be established wherever there were important watercourses spanned by Government bridges? I think it would be an excellent idea. It is quite necessary, in fact, to have this information, to complete the study of water supply.

855. Would not that information be valuable to you? Yes, very valuable.

856. In making the requisition for such gauges, it might be well to request that the information should be sent directly to you? I do not know what the views of the Commission may be, but I suppose that it will not sit for ever, and it is desirable that this information should be furnished regularly henceforward, and if it were sent to the Observatory it could include it in the rain record every year.

Daily records of height and velocity of rivers

857. Is there any other information which would be of value to you in connection with such an establishment? I presume that the record would be a daily record, showing the time at which the water rose and fell, and the velocity of the current; if so, that would be sufficient.

858. Is there an existing arrangement whereby the Telegraph Department convey the information to you? Yes, it is sent without charge.

859. Of course it would make no difference if the quantity of information sent was slightly increased? I do not think so. Every morning the operators send down messages to ascertain whether the lines are in working order, and it is just as well that they should send this information as any other ordinary messages.

860. We have prepared a list of questions which we intend to send out to surveyors, landholders, and others. The questions will be accompanied by a circular and a skeleton map. One of the questions which we propose to ask is: "Would the impounding of flood-waters in the rivers and creeks in your district, by means of dams, and limited to the natural holding capacity of such watercourses, be prejudicial or beneficial to the interest of the general public?" There are many places in which water is so impounded at the present time.

Impounding of flood-waters in rivers and creeks

861. But in those cases it is on the holding of one person? As far as I could hear it is a common practice in many parts of rivers, especially upon the Darling. There are many cases on the lower parts of the Darling where water is conserved in that way. On one run there, there was a dry swamp which no doubt had been originally connected with the Darling. Some years ago a canal was made and it filled this swamp. It was flooded in 1870, 1875, and 1879. There has not been any water let into it since the rise of the river in 1879, but there is nevertheless water in the swamp. There are several of such instances upon the Darling River. There is an enormous natural reservoir close to Menindie, and I think you might add to your list a question to the people in that neighbourhood as to what has actually been done in this way.

Canal to fill swamp.

Natural reservoir near Menindie.

862. In the case of the canal which you have specially mentioned, I suppose the water would be drained off only at a time of inundation? Only at the time of a flood.

863. Is the fall sufficient to prevent the water from running back into the river? Every provision is made for that. The proprietors of the Tolarno Station, who made the canal, sent me down a statement of the general facts with regard to it. I would suggest that one of these circulars should be sent to the telegraph master at Menindie. I know he takes a great interest in this matter, and I think he will be able to furnish to the Commissioner some valuable information.

864. Can you suggest any other particular in reference to which it would be desirable to obtain information, or any other means by which we could obtain it? If you carry out the river records at points higher up than those which I can reach it would complete the work, so far as that particular is concerned. The number of rain records is increasing every day. I constantly receive offers from different persons to make observations, and fresh records are being sent to me. I do not think anything need be done to increase the completeness of the records in that way—they are becoming more complete every day; but it is desirable that some proper record of the rivers should be kept. I am quite sure the Commission will see from what I have said that the river records which I can obtain are quite insufficient for their purpose. As far as I can gather, you would not find one place in twenty where an exact record has been kept by private observers. The only cases which I know of are those of the record kept by Mr. Tebbutt, at Windsor, and by Mr. Gell on the Murray.

Increase of number of rain records.

Mr. Tebbutt and Mr. Gell's records.

865. *Mr. Gipps.*] Do you think that Mr. Gell's record is reliable—it appears to me to contain some remarkable inconsistencies? As far as the velocities are concerned, you must remember that the same amount of water does not always mean the same velocity. I do not know upon what Mr. Gell's calculations are founded.

Prevalent winds west of the main mountain range.

866. *Chairman.*] Have you any records of the prevalent winds in spring, summer, autumn, and winter, in the country west of the main mountain range, as to the quarter they blew from, their force or pressure at different heights above the surface of the ground, and their average pressure per diem? I have no particulars concerning the heights above the ground. We have records of the wind from many places west of the main range, but they are not taken from self-recording registers.

867. *Mr. Gipps.*] You have no self-recording stations? None but Sydney.

Value of wind records.

868. Do you not think that these observations are of great importance? I do not think the wind record would be of much value; as a rule you get very little wind in the interior.

869. I should have thought they would have been valuable in connection with the wind-power; take the town of Stockton, in California, for instance—almost all the water consumed by that town is obtained by means of windmills? That is the case almost everywhere upon the Sacramento Flat, but that is close by the sea, and therefore a windy place.

870. *Chairman.*] Does the direction of the wind seem to influence the humidity of the air? Yes; west of the range rainfall comes generally with a westerly and north-westerly wind.

Winds preceding droughts.

871. What winds usually precede droughts? I do not think I could answer that question.

872. Do the winds which precede them blow continuously from any one quarter? No. As I have said, there is so little wind in the interior that you can hardly determine a general direction. The winds are very variable. In the west, when wind descends, it is dry; when it rises, on its way back to the sea, it is moist. If a wind rises over the main range, it brings rain. That same wind may have been driven inland by easterly gales. It is dry to the west of the range, but when the wind returns it rises and rain is deposited.

873.

873. To what depth of water and soil do solar rays take effect? Earth temperatures are recorded in Sydney at various depths, down to 19 feet 6 inches; I have no record below that. The highest temperature recorded at 19 feet is 65·8°, and the lowest is 59·70°. At 2 feet 6 inches the range varies from 64° to 52°, or about 12 degrees. H. C. Russell, B.A. 14 Aug., 1884.

874. *Mr. Gipps.*] Is that in soil or water? In soil. Effect of solar rays on soil and water.

875. Your observations have no reference to water? No.

876. Then it would be actual temperature? Yes; the thermometer is buried, and the observation is taken from that.

877. You have no observations with reference to water? No. I have the temperature of the water in Sydney Harbour, 3 feet from the surface, but that is affected by the tidal water.

878. You do not know to what depth the atmospheric temperature affects the water? I have no record of it.

879. Do you consider that the prevalence of a particular wind, or the frequency of rain in any locality, is influenced by the proportion of humidity in the air? I think it is the other way—humidity is influenced by the wind. Influence of wind on humidity of air.

880. What is the daily range of humidity in the eastern, centre or hilly, and western districts? I could not answer from memory. It is impossible to ascertain the range of humidity unless you have self-recording instruments. Range of humidity.

881. Would it not be possible to obtain them? The expense would be considerable. We have them in Sydney.

882. *Chairman.*] I suppose the chief difficulty as regards their employment in the interior would consist in getting people to take the observations? Yes; the chief difficulty lies in the neglect of observers to keep the thermometer wet.

883. Could you tell us how many degrees the dew-point generally is above or below the temperature of the atmosphere in the districts I have already named? The dew-point is seldom or never published by any Observatory. The reading of the wet and dry bulbs from which the dew-point is calculated are published, but we give the relative humidity in preference to the dew-point. Dew-point.

884. *Mr. Gipps.*] Do you not consider it reliable? Humidity is considered of more use. The dew-point is troublesome to calculate, and it is of little use, and from published observations the dew-point can always be obtained if wanted.

885. *Chairman.*] What is the mean force or pressure of vapour in the atmosphere? It could be arrived at from the published records. Pressure of vapour in the atmosphere.

886. Do you consider that in the summer months, namely, in November, December, January, and February, the humidity of the air in the western district reaches saturation point? It seldom or never reaches saturation point in the western district; it does not often do so in Sydney. Saturation point of humidity of the air.

887. What is the percentage of vapour in the air at such high heats in proportion to what it might hold? In extreme cases we have a humidity as low as 30 per cent., that is to say, there is only 30 per cent. of that which might actually exist. That is an excessive dryness, and it is seldom exceeded. It is only found about once in a year. Percentage of vapour in the air.

888. Do you think that such low humidity is prejudicial to vegetation? Of course a humidity which I have named exists only in a severe hot wind. Vegetation is then affected as if there had been a frost; all the young leaves are cut off—the evaporation goes on so fast that it kills them. Evaporation.

889. What is the lowest pressure of vapour recorded in the dry districts? I cannot answer that from memory. I have published the results of many experiments on evaporation, in the paper which I have not yet given to the Commission. It contains some observations made by me, and detailed in a report given to the Meteorological Conference which met in Melbourne in 1881 (*Appendix* E 3). If the Commission desire it, I can send copies.

890. *Mr. Murray.*] Mr. Czarlinski described an instrument used for testing evaporation—it was a glass tube, with discs of blotting-paper? I do not see how you can get by that means at the evaporation which takes place from the soil or from water. Nature does not hang up a piece of wet material to dry. I should not think that test of any use in measuring evaporation. Any such contrivance measures evaporation under conditions unlike those which exist in nature, and is therefore of no use for practical purposes. Evaporomètre.

891. I believe Mr. Czarlinski's contention is that the water is absorbed under the same conditions as those which exist on the earth's surface? I do not agree with him. What we want to know is the amount of evaporation from water and soil, and I think we must measure its amount from *water* and *soil* if we would have a correct result. Evaporation from water and soil.

892. Do you think that if the humidity of the air could be preserved, even though the rainfall should be small, such a condition would encourage vegetable growth? Plants seem to grow better in air which is moist. There is no doubt that if you could keep it at anything like saturation point the plants would absorb a certain moisture. Effects of humidity of air on vegetable growth.

893. Would the cultivation of forests over large areas have any influence in obviating the dryness of the air and in inducing humidity? I do not think so. My own conviction is that it certainly would not. The humidity would be greater in the forest, but only at the expense of the soil. Experiments made in forests show conclusively that they are equivalent to a drying machine, as far as the rainfall is concerned. Influence of forests.

894. *Mr. Gipps.*] But they keep a certain amount of humidity in the air? Yes, as I said just now, at the expense of the soil, for they pump it up by their roots, and the wind carries it away.

895. Have you made experiments with the potometer for testing the humidity given out by different plants and trees? Careful observations have been made as to the effects of forests in Europe. A moderate-sized chestnut-tree, for instance, has been taken as an example. The exact amount of water evaporated has been discovered, and it has been found that such a tree can get rid of about 16 gallons of water a day. In America it has been shown that forests have no effect at all upon the rainfall; that the plains in the neighbourhood of forests have as much rainfall as the forests themselves. The same thing is common all over this Colony; there is no more rain in the forest land than in the plains, if both are flat. Potometer.

896. Do you not consider that water would be more valuable if given out in this way and distributed through the air, than if it were allowed to sink into the ground and disappear into an under-ground basin, from which we could not obtain it? I think not. If you have trees in such abundance as to serve such a purpose, you could have no use for the land at all except the growth of timber.

H. C. Russell, B.A.

14 Aug., 1884.

897. But you are preserving the vegetation? You are preserving only trees. If you had that number of trees, you would certainly do away with the possibility of growing grass.

Records of temperature, evaporation, and wet and dry bulbs.

898. *Chairman.*] Have you any table showing the relative value of temperature—dew-point, rainfall, and evaporation? I have records of temperature, evaporation, and wet and dry bulbs; but, as I explained just now, I publish the humidity—not the dew-point.

Forests do not affect the rainfall.

899. *Mr. Gipps.*] Are we to understand that the more you denude the country of forests the larger the supply of water will be? I do not think you will get a larger rainfall; in fact I do not think it would make any difference. All the evidence I have seen goes to show that the cutting down of forests does not affect the rainfall. A great mistake was made by Humboldt years ago when he said, on very incomplete data, that the cutting down of forests had an effect upon the rainfall. He went into a place in South America; like many new districts in this country the forests were cut down and the timber was burnt; in a short time a lake near the place dried up, the town was left without any water and had to be deserted, and the timber, which was of a semi-tropical character, grew up again, and the water returned to the lake. Upon these imperfect data Humboldt said that the cutting down of the trees sent away the water. During the same years, however, Lake George, in this Colony, dried up and filled again. Not a single tree in this vicinity had been cut down, unless they had been cut down by the blacks. This shows conclusively, I think, that the reason of the drying up of lakes was a decrease in the rainfall affecting the whole world. Such changes are continually going on, and are shown by any general records. I have disclosed much the same thing in a rainfall map for 1882, showing that a variation in the rainfall of England and of this Colony was going on simultaneously. This must be due to some cause outside of the earth; it cannot be due to anything in the earth itself; it must be due to something affecting the amount of heat received by the atmosphere. No satisfactory evidence has been brought forward that the cutting down of trees produces a loss of rain. I know that such statements are made, and confidently made, with a large semblance of authority, and I know that in making the statements which I am now making I am saying that which is in opposition to the opinions of a great many scientific men; but on the other hand, it has been shown by Mr. Symonds and others that there is no indication of rain decreasing in Europe, in spite of the enormous destruction of forests during the 200 years over which the rain observations have extended, and the same has been proved of America by Professor Marsh and others. My own opinion is based on a careful study of the subject, and a comparison of all the facts which have come in my way. In our own country, for instance, a considerable amount of forest devastation has been going on for the last twenty years—I believe an unequalled amount of forest devastation; and during that time we have had a gradually increasing rainfall. It is true that the last year or two have been comparatively dry, but that is the result of some cause external to the earth, as is proved by the dry weather in the northern hemisphere, and has not been in any way due to the cutting down of trees, which has been continued in precisely the same way during the past two or three as in previous years.

900. *Mr. Gipps.*] Those who have travelled much cannot have helped noticing the difference in the rainfall in heavily and lightly timbered country? Yes, I know that is a common impression; but it is, I think, more than probable that it puts cause for effect, *i.e.*, that the rain causes the forest—not the forest the rain.

THURSDAY, 21 *AUGUST*, 1884.

Present:—

Mr. BARTON, M.P.,	Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E.,	Mr. M'MORDIE, B.E, C.E.,
Mr. GIPPS, C.E.,	Mr. TOWNSEND.

W. J. LYNE, Esq., M.P., President, in the Chair.

Charles Smith Wilkinson, Esq., F.G.S., F.L.S., called in and examined:—

C. S. Wilkinson, Esq., F.G.S., F.L.S.

21 Aug., 1884.

901. *President.*] Your name is Charles Smith Wilkinson, and you are the Government Geologist? I am an officer of the Department of Mines, and my official title is Geological Surveyor in Charge.

902. For what length of time have you held that position? About ten years.

903. I presume that you have travelled nearly all over the Colony? Over the greater portion of it.

904. And you have had opportunities of inspecting the different geological formations? Yes.

905. Have you travelled much over the northern portions of the Colony? Yes, to within 20 miles of the Queensland border.

906. Have you been on the northern rivers at all? I have been at the heads of the M'Intyre, the Severn, and the Mole Rivers. I have examined the country in the district of Inverell.

Nature of formation in district of Inverell.

907. What is the nature of the formation there? Chiefly granite and older primary rocks.

908. You would call that impermeable country? Yes.

909. Have you been lower down the M'Intyre than that? Not below Inverell in that district.

910. Taking the country as a whole, are there any permeable strata through which the rainfall would get away? Certainly not, except through irregular local escapes, through quartz-reefs and irregular fissures which occur here and there, but not through the regular strata.

Mining shafts.

911. Have you any sections of wells in that part of the country? No; but I have particulars respecting mining shafts sunk in the district.

Mining shafts at Emmaville.

912. Can you give us any information respecting those? Yes, I have some information respecting those sunk on the deep leads at Emmaville.

Depth.

913. What is about the depth of those shafts? If I remember rightly, about 200 feet. Nearly all the shafts were dry until that level was reached—I forget the exact depth—and then a great abundance of water was met with, necessitating the use of pumping machinery.

914. What was the nature of the strata passed through? Clays and basalt.

915. Then the inference would be that when the shafts reached that particular level they reached country which was impermeable below? Yes.

Water supply.

916. Have you any similar information respecting gold or other mines in any other part of the Colony? No, I have no information regarding underground water-supply from mines, excepting those in the Guigong Forest Reefs and Lachlan Gold-fields.

C. S. Wilkinson, Esq., F.G.S., F.L.S. 21 Aug., 1884.

917. You mentioned Emmaville? Yes; the shafts to which I refer have been sunk near there.
918. Do you know anything about any shafts sunk elsewhere in that part of the country? Yes, in the Cope's Creek district, to the south, there are deep leads similar to those, and continuing to Inverell.
919. Is the country of a similar nature? Yes.
920. Did they find there that when they reached the depth you have stated water came in in abundance? Yes; and I may mention that these deep leads are old river channels which have been filled up by sand, clays, and basalt, and therefore they carry the underground drainage of the country. Old river channels.
921. Have you ascertained whether they continue any distance? They must continue right to the plains.
922. I suppose that the water which accumulates and goes down the old river-beds does not appear again on the surface? No.
923. Do all those channels drain in the direction of the plains? Yes, that is, westerly. Direction of drainage.
924. Are these river-beds met with in any other part of the north of New South Wales? I have seen evidence of them all along the flanks of the Dividing Range. Old river-beds along flanks of Dividing Range.
925. South of the point you have described? Yes.
926. Can you mention any particular localities? Yes, in the Armidale district; in fact at irregular intervals all along the Dividing Range you find great tracts of basalt. The lava has flowed down and filled up some of the old valleys and now forms the plains, so that we cannot indicate exactly under the plains where the leads occur. All that we know is that the old drainage system, which was uniform throughout the Colony prior to the basaltic outbursts, has been covered up by lava in places. Old drainage prior to basaltic outbursts.
927. Then you would expect to find water lower down, underneath the lava? Yes. Water under lava.
928. Going south from Inverell to the mines near Orange and Lucknow, do you find the same thing there? Precisely the same physical features.
929. I suppose the water there would be trending down towards the Macquarie and the Bogan? Yes, it flows westerly, but the lava at Lucknow flows in a south-westerly direction, while the drainage of the country flows to the north-west. The lava flowed into the old valley and formed a new watershed which diverted the rainfall, but the general trend is westerly. New watershed.
930. Have you any idea how far west the lava flows? In that district it does not extend beyond about 25 miles from Orange. Extent of lava.
931. Does it continue about the same parallel north? No, the volcanic outbursts occur at irregular intervals all along the Dividing Range.
932. What I want to ascertain is the mean distance that the lava has extended westerly from the Dividing Range—to what degree do you consider it extends? A line drawn from Albury to where the 149th meridian crosses the Macintyre River is approximately the western limit of the basaltic outbursts. Western limit of basaltic outbursts.
933. From the top of the Dividing Range approximately to that line, where would you expect to find the water; the rainfall gets away on the surface, and I suppose the water will be found underneath the basalt? Yes.
934. What is the nature of the country beyond the limit of the basalt? The surface is generally covered by sandy loam and clay deposits forming the plains. Soil of the plains.
935. When the water gets to that point will it be found underneath the clay? Yes.
936. The clay takes the place of the basalt? The clay overlaps the basalt in places. Since the lava outbursts the rainfall has swept a lot of *débris* from the Dividing Range, and this *débris* has partly covered the basalt. Clay and basalt.
937. Do you know of any instance where the water appears further out in the plains in the shape of springs? There are numerous springs throughout the whole of the western country, but they are mostly due to local causes.
938. You do not consider that the water comes from the Ranges? Not in all instances.
939. Have you known any instance where these old river-beds have been traced further into the plains than the edge of the basalt? Fresh water has been got in many wells, but I am not aware of any system of underground channels having been discovered under the large plains. Old river-beds in the plains.
940. Do you know of any instance where the old river-beds have been struck in the western country? No. If you will allow me, I will refer to a report which I drew up for the information of the gentlemen who were appointed a Commission to inquire into the working of the Land Laws. My report is—"On the prospect of obtaining fresh water below the surface in the districts beyond the rivers Lachlan and Darling and beyond the river Darling." Since I wrote that report I have travelled over country which up to that time I had not examined—the vast plains to the west, extending to the Barrier Ranges. I should like to hand in this report, because there is nothing in it which I desire to alter materially. It expresses my views on the subject clearly. I have only to make a few additions to it. There are five formations in which water may be found (*Appendix* F 1):—1st. In the recent alluvium chiefly along the main rivers and creeks. 2nd. In the older alluvial deposits which form the east plains of the low-lying portions of the Darling and Lachlan Districts. In these, however, salt water is of frequent occurrence. Area, 118,000 square miles. 3rd. In the miocene marine beds. I am not aware if any wells have yet been sunk in these beds, but from their lithological character I believe that they will yield abundance of fresh water. Area, 22,000 square miles, underlies No. 2. 4th. In the cretaceous formation. This is a most important source of supply, and one which will probably yield artesian water. Area, about 32,000 square miles. 5th. In the palæozoic rocks, but the occurrence of a large supply of water of good quality in these is exceptional. Area, about 22,000 square miles. Since I wrote that report I have ascertained that water has been struck in two or three wells in the cretaceous formation, thus proving my remarks to be correct. Report to Land Laws' Commission. Water-bearing formations.
941. At what depth? From 80 to 427 feet.
942. Where do you suppose the water came from—is it surface water? Not local surface water. I may explain to the Board that a feature of the geological formation of New South Wales which is not generally known is that at present there is a main dividing range running parallel with the coast. In the early times, before the present epoch, there was also a dividing range running off at right angles from the existing coast range, and extending from about the middle of New South Wales, say in the Bathurst district, in a north-westerly direction, right through Western Australia. This range consists of primary rocks. Source of the subterranean water. Old dividing range.
943. *Mr. Gipps.*] Can it be traced now? The rocks may be traced near the surface, but owing to the enormous denudation that they have since undergone, the country has been levelled down in places, and covered by pleistocene deposits. At that time when the range existed all the land coloured light blue

C. S. Wilkinson, Esq. F.G.S., F.L.S.

21 Aug., 1884.

on the map which I produce, situated in the north-western portion of our Colony, and extending right away to the Gulf of Carpentaria, and probably to Port Darwin, was under the ocean. There the cretaceous beds were deposited, and this range formed the southern margin of this cretaceous ocean. In all such deposits where there are such huge basins as that to which I am referring, the strata always incline up to the margin of the shore line; therefore by sinking in any part of this deposit we are sure to get water which will rise to the level from which it soaks in around the edge of this old shore line; because the first beds deposited in this ocean in places near its shore were of rough stones and gravel washed from the hills, the lighter material being swept further away, and when it settled it formed clay and mudstones. By compression these mud-stones and clays have formed the impermeable beds through which we would have to sink before striking the lower gravel beds. Wherever this country is lower than the old shore line, the water when once struck in the gravel beds will rise to the level from which it comes around the flanks of the range.

Cretaceous ocean.

Rise of water.

944. *President.*] So that if the water comes from the range which is partly covered, it will not rise to the surface of the land further on? Yes, it will; because the clay beds which dam the water back run right against the beds deposited at a higher level. For example, at Dunlop's Station a well was sunk 670 feet before water was struck, and then it rose to within 10 feet of the surface. That is a higher level than the gap or channel of the Darling River. The clay beds which were pierced in this well ran against the flank of the range at a lower level than the present Darling Gap, which is quite a recent feature.

Darling Gap.

945. *Mr. Gipps.*] What is the depth of the Darling Gap? It is not known. I think it is very shallow, because the gap exists between formations which are only about 5 miles apart, and you see rocks cropping up on the surface about there. Therefore, I think that the Darling Valley would be very shallow.

946. *President.*] What is the difference between the height of the surface of the Barrier Range and the north of the Darling? I am not aware—I forget what the exact height of Wilcannia is above the sea-level.

Wilcannia, on south side of old range.

947. *Mr. Barton.*] Is Wilcannia on the line of the old range to which you refer? It is on the south side of it. Some of the country is 1,000 feet above the sea-level. There have been local upheavals to cause this.

Mount Murchison.

948. *Mr. Gipps.*] I suppose that remark would apply to Mount Murchison? Mount Murchison is a denuded portion of the old range.

Extent of old range.

949. *President.*] Have you any idea how far south it extended beyond the Queensland border into South Australia? The maps show that the range runs round into South Australia to the Flinders Range, forming the southern margin of the cretaceous area. I have travelled across the country to Adelaide, and have seen the primary rocks cropping out at the surface for nearly the whole distance.

Water from bores in South Australia.

950. *Mr. Gipps.*] Then the adjacent country must be almost like an inland sea? Yes. In South Australia a bore was put down 1,220 feet, and when water was struck it rose 20 feet above the surface.

951. *President.*] That is in the basin I suppose? Yes. A short distance to the west another bore was put down 330 feet, and the water rose 40 feet above the surface. That was at Hergott Springs. In this case the bore was 8 inches diameter, made by a diamond drill.

952. *Mr. Townsend.*] Did it choke much with sand? No, there was no trouble with sand.

Its source.

953. *President.*] Do you think the water comes from different strata in the two cases? I think not, because the western bore is not far from the watershed, that is from the range. The 1,200 feet bore was almost in the centre of the basin. The reason of the water being struck at a shallower depth in the other bore was because it was so near the edge of the basin.

954. Your theory is that the water that is struck in these two bores came from the range to the basin? Yes.

955. It is not water that comes from Queensland or from the heads of our rivers? Not exactly; it is water that has soaked into the formation around the flanks of the old range.

956. Have they tested the depth of that water in North-west Queensland? Not that I am aware of—I am not aware of any water having been struck there.

Flinders Range.

957. In speaking of the Flinders range, to which range do you refer? I mean the range to the north-west of Adelaide. Since I have been over the country I have been able to add to the cretaceous area the portion coloured light blue on the map. I desire to submit this map (*Appendix F* 2) because it shows the extent of the cretaceous area, in any portion of which artesian water is likely to be found.

Bar across the Darling.

958. *Mr. Townsend.*] Have you ever examined the rock in the bar across the Darling just below the township of Wilcannia? Yes, I have seen it.

959. Is that part of the old range? Yes, I think it is.

Barrier Range.

960. Do you consider the Barrier Range a continuation of that range? Yes.

Water south of it.

961. *President.*] You do not think there is any artesian water south-west underneath the Barrier Range? No, not under the Barrier Range; but south of the range you may get water by boring (say) about 400 to 1,000 feet. I think if bores were put down to that depth the water would rise to the surface or very close to it. The formation is quite different from that north of the range.

Formation south of Barrier Range.

962. What is the formation south of the Barrier Range? The surface of the plains is loam, sand, and clays, but south of this again on the line which I have drawn on the map, and to which I have referred in my report, there is another marine formation, in any portion of which I feel quite sure that fresh water can be obtained.

Miocene formation.

963. Does that water come from the Barrier Range? Yes; I think this miocene formation collects the underground drainage of the range. It is quite possible that this formation extends south to the coast of Victoria and South Australia, where the rocks form the cliff. We cannot tell how far it does really extend to the south, but I have no doubt that the underground water escapes into the ocean. That is proved by the underground channels which exist in the Mount Gambier district, where the water at some places is said to run at the rate of 4 or 5 miles per hour. This being limestone formation it is easily dissolved by the underground currents, and thus channels have been formed. There are no open channels in the great cretaceous area which I have described—there is merely soakage of water from the gravel-beds.

Underground channels in Mount Gambier district.

964. Do you say there are no old channels? There are no defined channels or caves, but there are layers of gravel in some places 10 feet in thickness, and extending probably 50 or more miles across.

Surface of the cretaceous beds.

965. Is the surface of the cretaceous beds in the northern basin impermeable? The surface of the cretaceous strata is impermeable, as a rule.

966. If the surface is impermeable, how do you account for the rain-water disappearing? The surface of the

C. S. Wilkinson, Esq., F.G.S., F.L.S.
21 Aug., 1884.

the range being impermeable, the water runs into creeks and gullies, and from these soaks into the gravel-beds which extend under the plains; therefore much of the water passes into the underlying cretaceous beds.

967. Then you say there are places where the surface water soaks down and gets underneath the impermeable strata? Yes, near the base of the hills or ranges.

968. And that we may expect to find artesian water all over that basin? Yes. Artesian water south of old range.

969. Does the same thing take place south of the range? Yes. I may explain that the layers in this formation are horizontal, and that where limestone occurs, it being easily dissolved, open channels may be formed.

970. Do you think that the water in the south-western basin comes from the western range in Queensland? I think that it comes from the range which runs into South Australia. Its source.

971. How far does the old range extend west—does it go as far as Western Australia? I am not aware, but I know that it extends to the north-west beyond Adelaide.

972. *Mr. Barton*.] Is it not a continuation of the Gawler Range? Yes. Gawler Range.

973. *President*.] Can you name any particular points where it exists in New South Wales or in South Australia? I have traced it from Wilcannia right across to Adelaide.

974. At what point does it cross our border? It intersects the boundary line where the 32nd parallel of south latitude crosses the border, and it goes across north of Wilcannia, making a curve to that point; thence it goes to Cobar, and from Cobar to Parkes, and from Parkes to Orange. Direction of old range.

975. From Cobar, I suppose, it forms the watershed between the Bogan and the Lachlan? Yes. Watershed.

976. *Mr. Townsend*.] I suppose you have seen the lakes at Mount Gambier? No, but I have read reports respecting them.

977. *President*.] I suppose you have inspected the Fish River Caves? Yes. Fish River Caves.

978. There is a stream of water there which has never been traced to its source? It is simply a local stream; it is only an underground stream for about a quarter of a mile. At the entrance there is a limestone rock, about 20 chains wide, running north and south, and the water goes through this and comes out again immediately below the caves, where it is an open creek.

979. *Mr. Townsend*.] The limestone is blue, hard limestone—not the ordinary limestone? Yes.

980. It is quite different from the limestone at Mount Gambier? Yes.

981. *President*.] Have levels been taken, and has it been proved beyond doubt that the water which comes out into an open channel at the Fish River Caves does not come from a submarine channel? I do not think that levels have been taken, but it must be obvious to any one who examines the locality that what I have stated is correct. Source of the water.

982. Is the water in the open channel continually running? Yes, but it varies according to the rainfall and the quantity of water running into the creeks above.

983. *Mr. Townsend*.] Have you noticed a similar thing in Cave Creek, near Orange? No, but there is a similar thing on the Bellabula River. Cave Creek, Bellabula River.

984. *President*.] You said it was well known that the water flowing from the Barrier Range southwards went underground to the ocean? Yes. Underground course of water from Barrier Range.

985. Do you know of any place where it has been traced to the ocean? I do not know of any particular outlet to the ocean, but there are underground rivers near Mount Gambier flowing in the direction of the ocean, which is not far distant.

986. Do you know whether it has ever been discovered that water in the ocean, for a short distance from land, has been fresh, or partially fresh, after heavy rains on land? No.

987. Do you think that the water which is contained in the extinct volcanoes, or lakes as they are called, at Mount Gambier, comes from the range to the north, to which you have referred? I gather from the Geological Surveyor's report of the district, which report was recently made, that the water stands at the same level in the lakes as it does in the strata, through which there is a current southwards. Water in the extinct volcanoes at Mount Gambier.

988. Does the water in the lakes rise and fall as the current in the underground river increases or diminishes? I cannot say. I do not think that there can be much rise or fall. These channels drain such an immense area of country that I think the level of the water would be almost permanent—it could not be affected by local rainfall. Rise and fall of water.

989. We have it in evidence that the water in the lakes does rise and fall at certain periods? The question is dealt with in a report prepared by the Geological Surveyor of South Australia, of which perhaps it would be well for you to get a copy. A great deal of information is to be obtained from the report of the Chief Officer of the Water Conservation Department in South Australia—that is, respecting deep wells and bores. Report of Geological Surveyor of South Australia.

990. Can you give us any approximate idea as to what portions of the Colony may be considered permeable and what are impermeable? Generally speaking, all the primary rocks are impermeable. Of course there are exceptions where there are quartz reefs and fissures. I have referred to that subject in my report. Permeability of rocks.

991. Would it be possible, from the information which you have collected, to mark on a skeleton map the position of the different kinds of rocks? They are shown in the geological map which I have produced. The areas marked in dark colours represent impermeable rocks, and those in lighter colours permeable rocks. I believe that on nearly the whole of the area marked in green and blue there are abundant supplies of water underground. Geological map.

992. Is the surface to the south of the range to which you have referred impermeable? No; it is all loamy sandy country, forming the plains, into which water soaks freely. Sandy country.

993. Is the country between the Murray and the Murrumbidgee permeable? Yes; all the Riverina country is. Permeability of Riverina.

994. Have you any particulars respecting wells sunk in that country? I have heard of a great many wells having been sunk and of water being found, approximately, at the same level. Wells in Riverina.

995. Do you know that in that country after the clay beds have been pierced the water rises nearly to the surface? I have heard of that, but I have no information as to the exact height to which water has risen. Rise of the water and formation of the country.

996. The stratum which keeps the water down is impermeable? Yes. There are local clay beds. These plains have been formed by floods, which have washed down *débris* from the Dividing Range. In places where the current has been very strong sand and gravel have been deposited, and where the water was comparatively still mud has been deposited, which in course of time has become impermeable clay.

997. Will that apply to all the country between Wilcannia and the Murrumbidgee? Yes; the same general features will be found to exist right across that country. 998.

C. S. Wilkinson, Esq., F.G.S., F.L.S. 21 Aug., 1884.

998. This local formation has been caused by floods washing clay and *débris* from higher land? Yes. It is quite a different deposit from that in the north-western part of the Colony, which is all marine. The fact of its being a fresh-water formation in the country to which you refer is the reason why salt water is generally found in it, because the rain-water washing the dirt from the ranges caused it to be deposited quickly, and in course of time, owing to the moisture contained in it, the minerals decomposed, and made the fresh water salt. Sulphate of alumina, lime and magnesia, &c., have been formed, and thus salts have been chemically formed in these beds. In the marine formations the soluble parts of the minerals have been washed out by the long-continued action of the sea-water, therefore it is that you nearly always get fresh water in these beds. Wherever there is an underground current and the water finds an outlet through the underground beds there you will get fresh water; whereas, a hundred yards away where the water is stationary you will get salt water.

Fresh water in underground currents.

999. *Mr. Townsend.*] Have you ever examined the Coonapara Range? I have not.

Coonapara and Western Range.

1000. *President.*] Mr. Townsend says that in the locality to which he refers the beds in places are very permeable; the creeks come down "bankers" for a certain distance and then lose themselves entirely: can you inform us of any other places where that occurs? I have noticed it in many instances; it occurs all around the flanks of the Western Range—it is one of the common features in that part of the country.

Willandra Creek

1001. It occurs in the Maroo and Willandra Creeks? I believe that it does. With the permission of the Board I should like to read the report to which I have previously referred. I shall make some interpolations as I proceed.

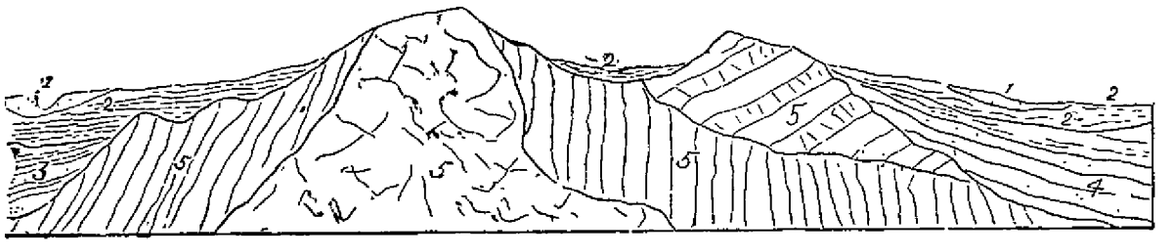
Report.

Report on the prospects of obtaining fresh water below the surface, in the districts between the rivers Lachlan and Darling, and beyond the river Darling.

In accordance with your request, I now report on the prospects of obtaining fresh water below the surface in the districts between the rivers Lachlan and Darling and beyond the Darling.

There are five geological formations which may be regarded as sources of underground water supply; 1. Recent: 2. Pleistocene and Pliocene; 3. Miocene; 4. Cretaceous; 5. Palæozoic formations.

The following sketch section will serve to show the relative position of these formations—



No. 1.—The recent deposits form the sandy and gravelly beds of watercourses, the alluvial flats bordering them, and the muddy accumulations in progress in swampy hollows. Good water is generally found in them at various depths, rarely over 40 feet, especially in the alluvial flats near the larger rivers and creeks, but seldom near the heads of the creeks. Therefore, in the latter localities, where water is most required owing to the rapid disappearance of surface water, they are of but little importance as sources of supply.

No. 2 are older alluvial deposits, of much greater thickness, being sometimes 300 feet thick, and more widely spread than those just mentioned. They compose those clayey and loamy plains which, commencing in the larger valleys, gradually spread out and form extensive areas of level country, such as we see throughout a very large portion of the districts under consideration. When we consider that these deposits, which consist of the disintegrated rock material swept down by floods from the higher lands, have filled up valleys and hollows in the old land surface, we can readily conceive that they absorb an enormous amount of the rainfall which becomes stored in the sand and gravels lying in the old hollows. As the existing surface features show little or no indications of the buried hollows, it is sometimes only by repeated boring or sinking that the water-bearing drifts may be discovered. The rain-water soaking into these deposits is, at uncertain depths, arrested by beds or layers of impervious clay. Where the water passes freely over these to lower levels it is generally of fresh or drinkable quality; but where it does not circulate freely but is retained for a long time in saucer-like depressions formed by the clay-beds, it dissolves much of the mineral matter of the strata and thus becomes brackish. In some respects, therefore, these underground stores of water resemble many surface lakes—the water in those having no outlet being often salt, while in those which have an outflow it is fresh. As these retaining clay beds do not usually extend far in any direction, it often happens that fresh water may be found in one well only a short distance from another yielding highly saline water; and after passing through a salt-water bed the next water struck may be fresh. These varying conditions are but what we might expect in strata which have been deposited in such an irregular manner. The practical results then of our observations are, that water is likely to be found in these deposits at different depths to 300 feet, that if salt water be struck it may be only patchy or local, and that fresh water may occur near or below the salt; and further, that the water being fresh is evidence of its having free circulation, and thus is capable of being traced for considerable distances.

No. 3. *Miocene.*—This formation is only seen in the banks of the Lower Darling; but there is little doubt that it extends under the No. 2 deposits, which form the level country south of a line drawn from Booligal on the Lachlan to Menindie on the Darling, thence west to the South Australian Border. One or two bores in this district would prove the existence or otherwise of this marine formation; and where it occurs I believe that abundance of fresh water will be found in it.* The probable depth of sinking will be from 200 to 500 feet, and though the water may rise to a higher level than when first struck, it is only when the water-bearing strata are covered by impermeable beds that it is likely to rise to the surface; and as the overlying deposits of No. 2 are generally of a porous character, the occurrence of artesian water in the miocene beds will be exceptional.

No. 4. *Cretaceous.*—If a line be drawn from 31½ south latitude on the western boundary of the Colony, thence north-east 140 miles, and thence south-east to the Darling River, thence following up the Darling until it crosses the Queensland Border, thence along that Border back to the north-west corner, it will approximately include the area occupied by this formation. In nearly the whole of this large extent of naturally dry country it is probable that a permanent supply of good water will be obtained by bores or wells sunk to various depths within 700 feet from the surface, and that the water may be expected in many instances to rise to the surface. The numerous "mud springs" occurring in this area may be regarded as natural artesian wells, the water being forced up through fissures in the cretaceous strata, and thus affording evidence of the great store of underground water which may readily be made available by tube bores of large diameter. At Wee Watta, on the Kallara Run, Mr. David Brown bored with a 4-inch tube into some mud springs, and at a depth of 144 feet obtained water, which flowed from the tube at a height of 26 feet above the surface, at the rate of 60,000 gallons per diem; but this quantity gradually diminished, owing to the tubes becoming filled with sand. The same gentleman was also successful in obtaining artesian water at the Mullyeo mud springs. On the Dunlop Run Mr. James Wilson struck a good supply of water in the cretaceous beds in the Mount Wilson well, at a depth of 488 feet, which rose to within 90 feet from the

* Water has recently been obtained at a depth of 160 feet, on Mr. F. L. Parker's Buckalow Station, about 30 miles north of the Darling and close to the South Australian Border. The supply is abundant and apparently permanent.

Since this note was made by Mr. Morris, I have been informed that water has been struck at Ita in the same district at 240 feet, and at Wonga at 270 feet.

the surface. In the No. 2 Kapiti well, 20 miles west from the Mount Wilson well, a splendid supply of water was met with at a depth of 572 feet, the water rising to within 10 feet from the surface. In another well at View Point Mr. Wilson obtained good water at 536 feet deep; this rose to within 40 feet from the surface. In sinking these wells salt water was passed through in the pleistocene deposits, which are here about 100 feet thick, overlying the cretaceous formation. C. S. Wilkinson, Esq., F.G.S., F.L.S.

The other day I ascertained that not far north of Wilcannia, where the cretaceous beds come in, several wells were sunk to between 245 and 301 feet, and after the cretaceous beds were struck the water rose to within 65 feet of the surface. As this is so near to the margin of the southern bed I am sure that if bores were continued to a greater depth the water would rise to the surface. This formation is of great importance, for by putting down bores to a sufficient depth I believe that enough water would be obtained to supply the whole of that country. In one Government bore, 50 miles west of Bourke, good water rises at the rate of 600 gallons per hour from a depth of 201 feet, and flows from a pipe 21 feet above the surface of the ground. In another Government bore, 6 miles further west, from a depth of 427 feet, water flows at the rate of 180 gallons per hour at 3 feet 3 inches above surface; bore still sinking. 21 Aug., 1884. Rise of water in wells in cretaceous beds.

The importance of the information afforded by these discoveries and by the wells of the Mount Poole district cannot be over-estimated; for, taken in connection with the geological evidence, it assures us of the almost certainty of obtaining an abundant water supply from the cretaceous formation, which here occupies an area of about 40,000 square miles, though covered in places by alluvial deposits.

No. 5. *Palæozoic Formations.*—These include the Silurian, Devonian, and carboniferous sedimentary formations, consisting of slates, limestone, sandstone, and conglomerates, together with granitic and trappean rocks. These rocks appear at the surface and form the hilly country between the Upper Bogan River and the Lachlan, and with the exception of several irregular intervals of low-lying country, extend in a direction west-north-west right across the centre of the Colony, embracing an area of about 22,000 square miles. As a rule these formations are of an impermeable character, and constitute the bed rocks upon which the cretaceous and newer sedimentary formations have been deposited; therefore, in sinking through the latter, when the former have been reached, it is almost useless going deeper with the hope of finding a good supply of water. There are however exceptions; for sometimes the older rocks are intersected by quartz and other veins and joint-fissures, which, acting as drainage channels, afford a supply of water, generally of brackish quality but suitable for stock; nevertheless the chances of meeting with such water-bearing fissures in sinking or boring is very uncertain.

The areas where these old formations come to the surface must therefore depend for supply upon the rainfall conserved in tanks and dams; and fortunately the hilly or undulating features which are generally characteristic of such formations present most suitable sites for reservoirs and form good collecting grounds. Such country then is not without its advantages for obtaining a storage supply of water; and though dependent upon the intermittent rainfall, yet, from Mr. Russell's valuable maps, it would appear that this is sufficient to supply properly constructed reservoirs capable of holding out through ordinary seasons of drought.

In the Silverton district, which suffered so much during the recent drought, all the small tanks failed; but tanks 80 yards square by 25 feet deep held out all through the drought, although the average rainfall is only about 9·4 inches. At Silverton, just before I arrived there in June, the town was partly flooded, although only about half an inch of rain fell. The water which ran down the gullies covered the flats 1 foot deep. In the creeks I saw flood-marks from 1 to 12 feet above the sandy beds. These facts show that although the rainfall may be small, yet where the primary rocks exist there is every facility for storing water; all that is wanted is the formation of suitable tanks. Tanks in Silverton district. Flood at Silverton.

From the foregoing observations it will be seen that there are five principal formations in which fresh water may be obtained:—

1st—In the recent alluvium, chiefly along the main rivers and creeks.

2nd—In the older alluvial deposits which form the vast plains of the low-lying portions of the Darling and Lachlan Districts. In these, however, salt water is of frequent occurrence. Area, 110,000 square miles.

3rd—In the miocene marine beds. I am not aware if any wells have yet been sunk in these beds; but from their lithological character I believe that they will yield abundance of fresh water. Area, 22,000 square miles; underlies No. 2.

4th—In the cretaceous formation. This is a most important source of supply, and one which will probably yield artesian water. Area, about 40,000 square miles.

5th.—In the palæozoic rocks, but the occurrence of a large supply of water of good quality in these is exceptional. Area, about 22,000 square miles.

The above-mentioned areas can of course be only approximately stated until the extent of each formation has been ascertained by survey.

I have not referred to the natural springs which occur in many localities; for though they have underground sources, they may be more properly included with ordinary surface supplies such as are found in rivers and creeks.

Some remarkable instances of springs and wells are given by Mr. T. K. Abbott, P.M., of Gunnedah, in a paper "*On Wells in Liverpool Plains,*" read before the Royal Society of New South Wales in 1880. This paper affords much valuable information regarding the existence of fresh water beneath the surface.

The area of the whole district under consideration, viz., that extending from the Lachlan River below Forbes to the northern and western boundaries of the Colony—comprises about 194,000 miles; and the number of sheep within it, according to the Report for 1881 by Mr. Bruce, Chief Inspector of Stock, is 16,428,000. Deducting from this 9,900,000 sheep as being depastured at the rate of one sheep to 3 acres on the country within 8 miles from the permanently watered rivers and creeks, there remain 6,528,000 sheep on the country not naturally watered, viz., 147,500 square miles, from which may be excluded 9,000 square miles for useless scrub lands.

Assuming, then, that this dry country has already been improved by means of tanks, dams, and wells to two-thirds of its pastoral capabilities between the Lachlan and Darling Rivers, and to about one-eighth on the north and west of the Darling, and allowing one sheep to 5 acres as its capability when permanently watered, it should carry 2,052,000 sheep in the former district and 5,830,000 in the latter, or together one-half the number of sheep more than it does at present.

Of the above-mentioned 138,500 square miles of unwatered country, 22,000 should be deducted for the area occupied by the palæozoic formations, which necessitates a superficial storage of water. We have thus 117,000 square miles which may be supplied from underground sources, and 44,000 square miles of this area lie to the north and west of the Darling, in more than half of which artesian water is likely to be obtained. As we have seen that the present pastoral capabilities of this dry country may be increased eight-fold when it has been sufficiently watered, an approximate estimate may be arrived at of the value of the land in this portion of the Colony.

The soil in many localities is suitable for agriculture, but on account of the aridity of the climate and the irregular periods when the rain falls, cereals cannot be produced with any certainty.

I would here point out that the palæozoic areas (No. 5) may be regarded as comprising mineral lands. Gold, as at Mount Brown; silver at the Barrier; copper at Cobar, Nymagee, and Mount Hope; coal near Dubbo; galena, &c., have been found thereon, and further discoveries will probably lead to the settlement of a considerable mining population.

The accompanying geological map shows the position of the formation referred to.

I have not considered it necessary for the purpose of this report to enter into further detail regarding each formation. Such information will be found in the report by Mr. H. Y. L. Brown, geological surveyor, on the Geology and Artesian Wells of the Albert Gold-field, Warrego, &c., published 4th November, 1881.

In the Annual Report of the Inspector of Stock, 1880, I reported conjointly with Messrs. Bruce and Gilliat upon the subject of water supply for the stock routes through the north-western portion of the Colony.

I append an important paper by Mr. H. C. Russell, B.A., Government Astronomer, on "*The River Darling—the water which should pass through it,*" read before the Royal Society in 1879; and from this paper some idea may be formed of the sources of the underground supply.

Mr.

C. S. Wilkinson, Esq., F.G.S., F.L.S.

21 Aug., 1884.

Mr. W. E. Abbott, of Wingen, gives much interesting information regarding the natural features and water resources of part of the Darling District, in a paper entitled "*Notes of a Journey on the Darling,*" read before the Royal Society of New South Wales in 1881.

Professor W. J. Stephens, M.A., has contributed to the Sydney University Review, July, 1882, an able article dealing in a general manner with the subject of Artesian prospects in New South Wales.

PUBLICATIONS REFERRED TO IN THE FOREGOING REPORT.

On Wells in Liverpool Plains.—By T. K. Abbott, P.M., Gunnedah. (Read before the Royal Society of New South Wales, 3 November, 1880.)

Report upon the Albert Gold-field, together with a description of the geological formation of the Paroo, Warrego, and Culgoa districts, north of the Darling River, especially with reference to the existence of artesian water (to which subject reference is made in the Reports of the Department of Mines for the year 1880).—By H. Y. L. Brown, Geological Surveyor. Printed, 4 November, 1881.

Albert Gold-field—Artesian Water.—By C. S. Wilkinson, Geological Surveyor in Charge. (Printed, 15 November, 1881.)

The River Darling—the water which should pass through it.—By H. C. Russell, B.A., F.R.A.S., Government Astronomer. (Read before the Astronomical Section, 1 August, 1879.)

SOME considerations respecting the rainfall upon the basin of the river Darling led me to make a few figures in order to test an opinion I had formed some time since, to the effect that but a small part of the rainfall, after making every allowance, passes down the river. I was not however prepared for the result which I obtained, and as it throws some light upon our river system, I thought it would be interesting to the members of Section A.

The basin of the Darling is considerably more than 200,000 square miles, but for my present purpose I have assumed that it is only 200,000 square miles. A great part of this consists of the western slopes of the Great Dividing Range, extending from Orange northwards into Queensland, and upon this part of it the rainfall in an average year ranges from 20 to 40 inches; in the more western districts drained by the Darling the average is from 10 to 20 inches. I have taken 16 inches as the average fall all over it, and this is beyond question under the true amount. Now, upon the best part of the drainage, *i.e.*, the western slopes, it may safely be assumed that ⅛ of the rainfall, averaging there about 30 inches, gets into the rivers; upon the flatter portions this proportion would be less, but in order to make allowance for this, and for the effects of evaporation and be quite within the quantity of water which must run off the land, I have assumed that only part of the rainfall reaches the river.

At Bourke the Darling is said to be 60 yards wide. I have assumed it to be 200 feet, and that instead of the contraction in its channel below the water surface, it has a rectangular section. Its velocity when in flood, 32 feet above summer level, has been carefully measured, and was only two-thirds of a mile per hour, though it has been said that in contracted parts of the river lower down it sometimes flows 1½ mile per hour. I believe the smaller measured velocity to be the more correct, but in order here again to make full allowance I have assumed the velocity to be 1 mile per hour. And I find that after making these allowances, in which you will observe that I have assumed the current to be more rapid and the river considerably more capacious than it really is, while at the same time I have taken the available rainfall at only 2 inches, I find that in order to carry off this small rainfall the river would have to be 100 feet deep; that is, that it would, in order to carry off the rainfall, have to flow as a solid stream of water 100 feet deep and 200 feet wide, at the rate of 1 mile per hour, without any cessation throughout the year. Now, we all know that the Darling not only does not flow in such volume even in the wettest season, but that in a year of average rainfall, such as I have assumed, it is not navigable for more than about six months, and even then does not carry one-third of the water shown above, and that in summer it is very low, and perhaps stops running. What then becomes of the rain-water? A large part of it must do, as it is known the waters of the Barcoo and other rivers do, viz., sink into the ground, to flow at some lower level.

These considerations point to an inexhaustible supply of water from wells, and we cannot be surprised that so many wells have been made and found to confirm the ideas here presented, and there can be no doubt that beneath the surface of our flat country there is an unlimited supply of good water.

It may be objected to the foregoing statement that one-half of the Darling watershed is so flat that very little if any water runs to the rivers, and therefore it is not fair to include it in the estimate. But even if this were true, and I do not think it can be proven, yet it must be admitted that it is over this flat country that so little rain falls; and if the drainage be confined, for the sake of argument, to the western slopes, where the land has a considerable fall, it will be necessary also to take the rainfall of this district, which is at least double of that assumed for the whole basin, and the area of these western slopes amounts to fully 100,000 square miles, so that the water estimated would come to the same. It should be remembered that the rainfall I have used is not that of what may be called a wet year, but simply an average year. What then must be the quantity of water in a wet season which finds its way underground to some outlet?

Notes of a Journey on the Darling.—By W. E. Abbott, of Wingen. (Read before the Royal Society of New South Wales, 1 June, 1881.)

Notes and Queries about Artesian Prospects in New South Wales.—By Professor W. J. Stephens, M.A. (Published in *The Sydney University Review*, No. 3, July, 1882.)

Effect of storage reservoirs on the underground currents.

1002. *Mr. Townsend.*] Suppose a large system of storage reservoirs were initiated along the older rocks on the surface, what do you consider would be the effect of that on the storage underneath in the cretaceous and other rocks? I do not think that it would affect it in the slightest degree.

1003. From what source do you suppose that the underground reservoirs draw their supply? From the same source, but the rainfall is much in excess of the quantity which you could possibly store by tanks or dams.

1004. Suppose it were possible to store all but that which would be evaporated, would the underground supply be affected? I do not think that it would affect it much, if at all. These beds are more or less horizontal right up through Queensland, so that if the source of supply of which you speak were stopped, an underground supply would still exist.

Local rainfall over impermeable beds.

1005. Do you think that the water which falls locally on these beds forms an artesian supply? No, because it cannot go through the impermeable beds. I think that the greater part of it is evaporated.

1006. Then it is only where there is an outcrop of permeable strata that the underground supply is supplemented in this way? Yes, from the ranges.

Soakage of the water of the Warrego, Culgoa, Paroo.

1007. *President.*] Have you any idea as to what becomes of the water in the Warrego, Culgoa, and Paroo Rivers? I think that it nearly all soaks into the newer formations which I have described as pleistocene and pliocene, which overlies the whole of the western area in great patches. In some places you will find clay-beds and sand-beds 300 feet deep. The water gets into these beds.

1008. It would be found in basins here and there? Yes.

1009. At a lesser depth than the water which would be found in the proper basin? Yes. If you will look at the map which I have produced, you will see what I may call islands of primary rocks on the surface in different places. All around these islands the water would soak through into the lower basins.

1010. That is, that where permeable and impermeable strata meet the water would get through? Yes.

Run of water at the head of the Darling.

1011. Have you any idea as to whether, at the head of the Darling River, the water gets into the lower or the upper basin? I think that the greater quantity of it runs down into the river-beds—in the basin proper—the cretaceous beds.

1012.

C. S. Wilkinson, Esq., F.G.S., F.L.S. 21 Aug., 1884.

1012. But when the water is concentrated and gets into the main stream at flood-time, do you think much of it finds its way into the lower bed? No; I think that it gets into that bed only where it meets with the permeable strata at the edge of the cretaceous area.

1013. How do you account for the disappearance of the water in the Macquarie reed-beds? No doubt the water soaks through these, but the fact that the water does not soak through in this way in the Darling is shown by the mud-springs. The pressure below is so great as to force the water up.

Indication of presence of water.

1014. Have you any information as to the kind of timber which is generally found where water exists at no great distance from the surface? In such localities different varieties of gum-trees are usually found.

Gum-trees on alluvial flats.

1015. That would be where small basins are formed? Yes, in the Barrier country, in the valleys among the primary rocks, wherever there is an alluvial flat containing soakage water you will find gum-trees. The existence of these trees is generally an indication that there is soakage water underneath the surface—it is only in such places that trees grow in that country.

Maps showing permeability of strata.

1016. I suppose it would be possible to have a map prepared, showing in different colours the permeable and impermeable strata, and indicating the places where the water would be likely to get under the impermeable strata? Yes; approximately only, because the whole of the country has not been surveyed. I can illustrate the main features of the permeable and impermeable formations.

1017. *Mr. Franklin.*] We should like to have the information to guide us in any local examinations we may make? Any plan which I could prepare might be misleading in that respect—excepting as a general guide; as there has been no survey and as no levels have been taken, the lines which I might draw might be several miles out.

Suitable land for storage reservoirs.

1018. Is there any large area on the upper part of the tributaries of the Darling where the land is impermeable, and where storage reservoirs could be constructed? Wherever the older formations crop out at the surface the water would not soak into the ground.

Interception of water, and its effects on floods.

1019. Do you think it possible to intercept so much of the water by reservoirs on the upper watershed as to prevent sudden floods on the plains in the north-west? I do not think it possible.

1020. Not by extensive works? No. At Inverell, for instance, I have seen floods coming down the Macintyre which no reservoir which you could construct would resist; I have seen water running down nearly half a mile wide and 30 feet deep.

Impossibility of retaining water by reservoirs to prevent floods.

1021. Would it not be possible to retain the whole of that water by making cuts from the river to the creeks, and erecting dams in these so as to keep the water back? Floods might be mitigated very much by diverting the water into other valleys and damming it up in them, but I do not think it would be practicable by a system of reservoirs to retain the whole of the water which would run down the rivers at flood-time—that is at anything like a reasonable cost; in fact I believe that a system of dams such as you speak of would do more harm than good, because they would have the effect of flooding the country above, as is the case at Wagga.

Natural basins for reservoirs.

1022. *President.*] Of course if a system of artificial dams were agreed upon, the basins above would have to be given up to them: in that case would it be possible to find natural basins where we could store a large quantity of flood-water? I do not think so; the slopes of the dividing range falling to the rivers are very steep, and there are no large basins in which you could store water.

1023. *Mr. Townsend.*] It is simply a matter of capacity? Yes; the floods which do damage, I suppose send down a hundred times as much water as it would be possible to conserve in any reservoirs which you could construct. It would only be in the case of small floods that you could conserve the water.

Impracticability of storing water at the heads of the Macintyre, Macquarie, and Gwydir.

1024. *Mr. Franklin.*] Past experience has proved that at a time of heavy rain sufficient water is brought down all the tributaries of the Darling to flood large areas of country at varying depths; this water disappears in the ground—very little passes into the main river past Bourke—and it seems to us that the proper way would be to conserve a large quantity of water in the upper watershed, by damming the natural valleys and thus preventing a sudden rush of water lower down? In the lower portions of the country you might store large quantities of water, but I do not see how it could be done on the highest slopes of the range—at any rate in such a way as to prevent floods. Take the Macintyre, the Macquarie, and the Gwydir Rivers; I know of no place on the upper watersheds of these rivers where you could make sufficient reservoirs to check the flood-waters.

1025. *President.*] Have you been on the Upper Murray? I have been in the Tumut and Adelong district, on the Upper Murrumbidgee.

Features of the Macintyre country.

1026. Is the country on the Macintyre where you have been similar to that? It is very similar on the higher portions; but in places there are table-lands, and water comes off these table-lands, but there are no depressions; they are nearly all deep valleys, across which a number of weirs or dams will have to be constructed to intercept the water. There is no place where you could divert water into a natural basin such as Lake George.

Nature of soil on the Lower Darling.

1027. Do you think that the soil on the lower part of the Darling is sufficiently impermeable to carry water in canals? For a year or so perhaps the water might percolate through, but after that the sides of the canal would become puddled; then the water would not soak away.

Formation of plains in India.

1028. *Mr. Franklin.*] Have you seen the plains in India? No, but from what I have heard, I believe they are formed in the same manner as our plains in the interior; that is by floods washing *débris* from the high-lands.

Sandy beds rendered impermeable through flow of water.

1029. In India they dam the rivers and divert the water into canals, which are found to be perfectly impermeable after the first season: do you think that that would be the case here? I have known races to be cut through sandy soil, and after the water has been flowing through it for a year they have become practically impermeable. In the Riverina country the water soaks away from some of the tanks and dams during the first season. The plan sometimes adopted there is, when the water gets away in the dams, to turn a flock of sheep into them, and thus to puddle them. I think that a scheme of canalization is perfectly practicable.

Plains near Booligal.

1030. You think, then, that by a system of dams and canals, we might convey large quantities of water over areas which are now waterless? Yes, I think there is every facility for that kind of work, such as on the plains near Booligal. The water may be diverted from the rivers into old channels without any heavy engineering work being necessary.

1031. It has been done at Oxley Station, below Booligal: do you know of any depression like that on the upper parts of the river? No.

Slope of rivers above Bourke.

1032. Have you any plans showing the slopes of the river-beds above Bourke? There are no such plans that I am aware of. I remember that, in one of Sir Thomas Mitchell's works, he makes special reference

C. S. Wilkinson, Esq., F.G.S., F.L.S. 21 Aug., 1884.

to the general fall of the rivers on the dividing ranges. I cannot remember exactly what he states, but if the information will be of any value to you I will try to get it. I am afraid that the book was destroyed in the Garden Palace fire.

1033. Is the line of permeable country close to the watershed? It exists all along the flanks of the ranges.

1034. Would it be possible to intercept the water in soakage by mechanical means? I do not think so, because the outline of the country presents numerous jutting points, and it would take hundreds of miles of check dams to intercept the water.

Height above sea-level of outcrop of porous soil.

1035. *Mr. Townsend.*] Can you say approximately at what height above the sea-level the outcrop of the porous soil occurs? I think it occurs at about 500 to 1,000 feet, but it is not regular.

1036. *President.*] Do you know of any place on the river Darling where the bed of the river is higher than the plain on either side close to or within a reasonable distance of the river? I do not think that any sections have been taken, but it is very usual for river-beds through deltas to be much higher than the adjacent plains.

1037. Have you been on the Yanko? Yes.

1038. Have you examined the cutting there? No, it was not made at the time I examined that country.

Diversion of water from rivers into creeks.

1039. Do you think there are many places in the country where water may be diverted in the same way as it has been there? In many places a good deal of water could be diverted and stored as it has been done on the Yanko.

Impermeable coating of silt over river-beds.

1040. *Mr. Townsend.*] Do you not think that the silting which forms the impermeable skin over the river-beds rather militates against the idea of water soaking through the river-beds on to the impermeable strata? The water may not soak through in the actual channel of the river; but, as you know, in some places there are tributaries at intervals of about 100 yards, and where these occur the deposits in the river-beds must naturally be cut through.

Alluvial deposits on the Darling.

1041. Not along the Lower Darling? Certainly not; but some of the alluvial deposits on the Darling are so very sandy that the water must soak through. Mr. Russell, I think, states in one of his papers that wells sunk in the vicinity of the Darling are known to rise and fall as the river rises and falls.

Depth of sand in the mallee country between Hay and Wilcannia.

1042. *President.*] Have you examined the mallee country? Yes.

1043. Have you ascertained to what depth the sand goes? No, but I do not think it is very deep. It is chiefly blown sand. Between Hay and Wilcannia there are a number of sandy ridges, running north, east, and west, for miles, which have been blown there by the winds.

1044. I suppose that nearly all this sand rests on impermeable soil? I think so.

Old Man Plain.

1045. *Mr. Townsend.*] Have you been on the Old Man Plain? Yes.

1046. The clay there is impermeable, is it not? You get clay there, and in places it is covered with sand. I think all that country may be considered impermeable.

Increase of fall.

1047. *Mr. Franklin.*] Experience in India shows that the fall of tortuous rivers may be increased from 1 foot in the mile to 1 foot 6 inches by making direct cuts from the river parallel with its course; it is found that by making these cuts they get drainage from the natural deposits, and thus are enabled to bring the river-bed above the ground surface—in this way they irrigate very large areas of the adjacent country; it is also found there that the adjacent land is well adapted for canals, as it becomes almost impermeable after one season—Do you think it possible to find the same condition of things here? Yes, all through the low-lying country, because it is in this country where the deposits are of an alluvial nature that the rivers are most tortuous.

Coast range rocks.

1048. *Mr. Gipps.*] What is the age of the rocks of the coast range? As stated in my report, they are chiefly Silurian, Devonian, carboniferous, permian, secondary, granite, and volcanic.

Devonian rocks.

1049. Are the Devonian rocks of any thickness? In one place they have been proved to be 10,000 feet thick.

1050. Do you think that they would be of any great thickness in the western country? Yes.

Their porosity.

1051. Are they porous? Not as a rule. They are formed of quartzose sandstones, which are almost impermeable. They are much more compact than the Sydney sandstone.

Cretaceous beds at the surface at Silverton.

1052. At what level would the cretaceous rocks lie on the Devonian rocks? I have not made any calculations, but the only place where the cretaceous beds come to the surface is near Silverton. I have taken barometer levels, but I have not yet worked them out. I do not think they can be much more than 600 feet above the sea-level.

1053. At what height above the sea-level do the cretaceous rocks exist? About 600 feet.

1054. What is the average height above the sea-level of the old river-beds at their summit outcrops? What do you mean by outcrops?

1055. Where the rocks have been cut through? They have not been cut through in many places, but the rocks of the upper parts of the rivers are not unlike those which exist at Kiandra, which crop out at the side of the range.

Old river-beds.

1056. *Mr. Barton.*] Are there any surface indications which would guide us in finding these old river-beds in the formation of which you speak? The outcrop of the older formation might give some indication as to where the old river-beds exist.

1057. Do you know that the opinion is general among miners that you will find the deepest channels in the alluvial directly under the highest ridges of the floating basalt? I have noticed that myself in one place, but there it is purely local. The idea has arisen in the minds of the miners from the fact that they have traced deep leads under hills; but the continuation of the leads passes right under the river-channels also. The existence of these hills is purely accidental. From some cause or other they have not been denuded as the adjacent formation has been.

Fossil leaves and bones in old river-beds.

1058. *President.*] Fossils are found in these old river-beds, are they not? Fossil leaves and bones, which were deposited in the old river-beds before the lava has flowed over them. Fossils have been discovered in the deep leads at Gulgong.

Subterranean river at Gulgong.

1059. *Mr. Gipps.*] There is a supposed subterranean river at Gulgong—have you seen it? No; I know that in the deep lead at Gulgong there is so much water that miners have not been able to keep it down. That lead has been traced 10 miles further on, where it comes out to the surface, so that I cannot think that there is a subterranean river.

1060. Do you know anything about the shaft sunk close to the limestone formation there, in which the water has never been kept down, thus indicating that there must be a permanent stream? I suppose you refer to what is known as No. 44 shaft. The water in that shaft is soakage from the deep lead.

1061. It does not come from the limestone formation? No.

THURSDAY.

THURSDAY, 28 *AUGUST*, 1884.

Present:—

MR. BARTON, M.P.,	MR. LYNE, M.P.,
MR. DONKIN, J.P.,	MR. MURRAY, M.P.,
MR. GIPPS, C.E.,	MR. M'MORDIE, B.E.,

MR. TOWNSEND.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. E. O. Moriarty called in and examined:—

Mr. E. O. Moriarty. 28 Aug., 1884.

1062. *President.*] Your name is—? Edward Orpen Moriarty.

1063. What is your official designation? Engineer-in-Chief for Harbours and Rivers.

1064. You have occupied that position for many years, have you not? Yes.

1065. You have had considerable experience in connection with the rivers throughout the whole Colony? Yes, I have.

Surveys of Murray, Murrumbidgee, and Darling.

1066. Have you had prepared in your Department many sections of the rivers? I have had surveys made of the Murray, Murrumbidgee, and Darling, for the greater part of their length.

1067. Have we those surveys? Yes, I think so. Several surveys were burned in the fire at the Garden Palace, but all that were in my office were, I think, sent to you.

1068. What distance up the Darling did you have the surveys made? I think they go as far as Menindie.

1069. You have none as far as Bourke? Not a continuous survey from the lower end.

Test borings.

1070. In your Department have you had occasion to have test borings of the river-beds made? No, there have been no borings; there was no occasion for them, so far as I was concerned.

Water-supply of towns.

1071. You have also had considerable experience in connection with the water-supply of towns? Yes.

1072. In any case have you supplied towns with water by storage and by gravitation? The Sydney water-supply will be both by storage and gravitation. The supply to most country towns will be by pumping, but also by storage. We shall have to store water to tide over the dry seasons in most places.

Storage of water.

1073. In any experience you have had, do you think it would be possible to store large quantities of water at the heads of rivers, by taking advantage of natural basins? I have not made any examination of the rivers with that view. There is no doubt it could be done, but it would be an enormous expense.

1074. Have you had any experience of the water system of India? No, I have never been in India.

Irrigation.

1075. No doubt you are aware that they have gone to great expense there in connection with schemes for storing and distributing water for purposes of irrigation? Yes, I have read accounts of it in various books.

Unsuitability of the Indian scheme to this country.

1076. Do you think it would be practicable to carry out some such scheme here in connection with our rivers? No, I do not think it would; our rivers are totally different from the Indian rivers. For instance, there is no similarity between the Murray or Murrumbidgee and the Kistna, Collaroon, Godavery, and Ganges. I am simply telling you what I have read; I do not profess to know anything more than you could acquire by studying the works on the subject for yourselves.

Our river systems different from those of India.

1077. In what way do you consider that our river systems are entirely different from those of India? Well, the size of our rivers is insignificant in comparison with the size of Indian rivers. The dams on some of the rivers in India are a mile in length, and the rivers have sandy beds, which are quite different from the beds of our rivers.

Irrigation of the back lands.

1078. And is that your only reason for thinking that we cannot adopt such a system here—namely, that our rivers are smaller and do not carry such a body of water? I do not think it would be possible to throw the rivers over the adjoining lands in the same way as is done in India. I think that it may be done to some extent where there are anabranches which could be kept charged with water in ordinary seasons by a system of damming in the river, but as for irrigating the back lands I do not think it would be possible—I mean not financially possible.

Watering of the back country.

1079. Not financially possible? No; in India they have a teeming population, and all that is required to galvanize them into life is to give them plenty of water for their crops, but here we have no population to speak of. I think, however, that for pastoral purposes the back country might be much more permanently watered than it is at present.

Locking of the rivers.

1080. Do you think that might be done by a system of locking the rivers? Yes, but it should be done in connection with the navigation—I think the two things should be taken together.

1081. Then it would have to be done by a system of locking as well as damming? Yes, you would require the locks to enable the steamers and other vessels to pass.

1082. Do you not think that by a system of locking such rivers as the Murrumbidgee at opportune places where there are anabranches, natural watercourses, a great deal of water could be distributed over dry country? I have just said so; I think that might be done.

1083. In such places as Yanko would you stop navigation, or would you have a lock there? I would have a lock at all the weirs so that barges might get through. I think it is well worth while to keep up the navigation of those rivers.

Survey of the Murray and the Murrumbidgee.

1084. Have you been at the head of the Murrumbidgee or the Murray? I have not been above Albury. I have had the Murray surveyed from Albury to the junction of the Darling, and the Murrumbidgee surveyed from Gundagai to the junction of the Murray.

Snags.

1085. Are not surveys going on now? No, the operations we are carrying on now are for the removal of snags from the river-beds, snags that have been the accumulations of ages in those rivers. The first step in the improvement of any river is to take out the dead timber that has accumulated there, and as soon as the channel is clear we can proceed to lock it and construct weirs at suitable places.

Sections. Large scale surveys.

1086. In making the surveys that you have spoken of, have you taken sections of the river-beds? Yes, both longitudinal and cross sections, and in the large scale surveys all the obstructions in the river are shown, such as gravel-beds, fords, shallows, and so on. I sent the plans to the Commission. I may mention that some time ago there was a Company formed for improving the navigation of the Darling, and we sent tracings of the whole of our surveys to them as far as we had them.

Mr. E. O. Moriarty. 28 Aug., 1884.

Information from water supplies for country towns.

1087. The whole of the information you could give us will be contained in those surveys? Yes.

1088. The water supply to country towns that you are carrying out would not I suppose assist us in any way in our inquiry, because the measurements would be simply local? Yes, most of the towns we are dealing with now—Bathurst, Goulburn, Wagga, and Albury—all have pumping schemes; the water is pumped from the river into reservoirs, and distributed from the reservoirs through the pipes.

1089. And the other works you have carried out have been principally on the coast? Yes, harbour works.

1090. *Mr. Donkin.*] Has any gravitation system been brought into operation here in connection with water supply except the Prospect scheme? No.

1091. I think you said the water supply in all the other places was provided by pumping? Yes.

Cost of water conservation by dams.

1092. You said you thought it would be very expensive to conserve water by means of large dams? Well, I have no surveys of the heads of our rivers, and it may be rash to express an opinion, but I believe the cost would be enormous.

Prospect dam.

1093. What is the cost of the Prospect dam? £400,000 or £500,000.

1094. And what is the capacity for storage? Ten thousand million gallons.

Places for dams at heads of rivers.

1095. I suppose any number of suitable places like Prospect could be found at the heads of rivers? I do not know about that, because Prospect is low down on the river. When you approach the heads of the rivers you meet with precipitous country, and it would require an enormous sum of money to construct dams there.

1096. That would not be the case at the head of the Darling, would it? No, the Darling of course rises in Queensland.

Storage of flood-waters.

1097. But it flows mostly through flat country? Away from the table-land it does; above that the country is precipitous. A somewhat similar plan was proposed to store the flood-waters in France, and it was found to be enormously costly. Besides that, there is a great deal of danger in constructing dams on the main watercourses themselves. In this country we are subject to such terrific floods that any dams which might be constructed would need to consist principally of solid masonry, in order to resist the flood-waters.

Watering of back country in India.

1098. I suppose that one reason why the system would be more expensive here than in India is that the price of labour is much higher here? Yes. As far as I am informed, the Indian dams are not constructed at the heads of rivers, but low down on the flat country, where the banks have a slight rise above the river-beds, and where the back country falls away from the banks of the river. The highest point is just immediately on the river-banks and the country falls away on each side, so that by backing the water at certain points and by the construction of canals you can water a large extent of country. I do not think that could be done on any of our rivers, because the banks are pretty high, and to construct dams that would raise the water to the level of the top of the bank would throw the whole of the flood-waters over the adjoining country. I do not think any dams in our rivers should be more than 5 or 6 feet high.

Impracticability of dams.

1099. Do you not think that, by a system of damming, the flood-waters might to a great extent be conserved? I do not think it is practicable at the present time; I do not think there is population or money enough for any useful scheme.

1100. Have you seen the Lachlan River? No.

Damming the Lachlan River.

1101. For over 100 miles the summer level is only something like 50 feet below the banks: do you think it would be possible to dam the river where the banks are 40 or 50 feet above the ordinary level—do you not think it would be possible to store water there? No doubt it would be possible, but I do not think it would be judicious.

Water-supply at Forbes.

1102. At Forbes, for instance, they have completed a scheme of water-supply at a cost of £7,000, but just when it was finished the river ceased to run, and they have had no water? Well, I think the proper course would be to have a succession of small dams on the river above the town.

Banks of the Lachlan.

1103. You have had no surveys made on the Lachlan? No, but I had a reconnaissance made of it some time ago. I should doubt, however, unless you are well assured of it, whether the banks can be so high as 50 feet.

1104. I am sure that at Forbes they are fully 50 feet, and also from Cowra to Hillston? Well, you would have to pump the water from the river over plains.

Levels and cross-sections of rivers.

1105. In making the surveys you spoke of on the Murray, Murrumbidgee, and Darling, I suppose that levels were taken, but were any cross-sections made? On the Murray they were made every mile, and on the large plans, as I have said, all the obstructions are shown.

Gauging the rivers.

1106. Have you had any system of gauging the rivers? Yes; I established a system some years ago. I had a form prepared, and sent it to various persons in the interior, with a request that they would supply the information. This was kept up for some years, but of late we have found we could not get any returns.

1107. Do you think it would be advisable to have such a system of gauges established? They are used in some places. On the river Murray, at Albury, for instance, and at Echuca and some other places, there is a record published of the height of the river every morning in the local paper. That is a very useful plan.

Gauges above Bourke.

1108. I think there are no stations on the Darling above Bourke? I sent some forms of returns to the various owners of stations, with a request that they should be filled up so as to record the height of the water on a gauge every Sunday. I selected Sunday as being an idle day, and I got a great deal of abuse for the suggestion.

Gauges on bridges.

1109. *Mr. Barton.*] I think we have heard that you had gauges fixed on the different bridges that cross the rivers? No; but flood-levels are marked on all our plans.

1110. Yes; but I mean gauges for showing the height of the river at different places? We had gauges fixed on different parts of the rivers, but they have fallen into disuse of late years—I could not get the people to give me a return.

Discharge of rivers.

1111. Have you taken any means to ascertain the quantity of water that flows down the rivers at different times? That could be ascertained from our plans. Of course the water flows in a constantly varying quantity—there is scarcely ever the same quantity for two consecutive months. It is very easy to compute the quantity of water in times of flood, from the levels on our plans.

1112. You have no knowledge yourself of the matter—your information is obtained from the officers of your Department? Which information?

1113. The information as to the quantity of water that flows down the rivers at times of flood or half-flood? That knowledge can be obtained by taking the levels between two known points; then, having the cross-sections of the river, you can compute the velocity and quantity of water at each. That can be done from the plans.

Mr. E. O. Moriarty. 28 Aug., 1884.

1114. I understood you to say that the cross-sections were lost? Some were lost, but I cannot tell what they were. Mr. Gipps tells me that you did not apply for the cross-sections, so they may be in my office now. From the cross-sections and from the flood-levels you can compute the quantity of water that passes down the river-bed. We have exact levels at certain stated points, and we know the exact fall of water between those points.

Water escaping underground.

1115. I understand that perfectly well, but there is a notion that a very great proportion of water escapes underground, and that, taking two given points—say so many miles apart—there would be less water flowing at one point than at the other: I wished to know whether you had any data showing anything of the sort? I do not think that can be the case. I think that nearly all the water not thrown over the banks of the river passes down through the channel. Of course there is a great deal of waste water. I remember on one occasion going up the Murray in time of flood. We stopped to take in wood, and I saw that the man who was supplying us with wood had his whole family camped in the dray on the river bank. The water was up about 4 feet, and the dray was just a few inches above the water. The flood extended for about 10 miles on each side of the river. Of course a great deal of water would be lost from the channel in such a case as that. I am told that the Darling on one occasion was nearly 60 miles wide between the flood-marks on each side of the river at its junction with the Murrumbidgee—in fact it was like an inland sea.

Waste of water.

Width of Darling flood.

Victorian system of Water Trusts.

1116. *Mr. Murray.*] I suppose you are acquainted with the Victorian system of Water Trusts or Shire Councils? I have a slight knowledge of them.

1117. Do you think it is possible for us to adopt that system here? I do not know. There would be some difficulty about it, because the persons who would be called upon to pay for the works would not be the only persons benefited. Suppose you adopt a Dutch system of water conservation; any works that might be undertaken would not only benefit a certain class of people, but would also in a very much larger degree benefit the Crown Lands in the neighbourhood. Therefore the Crown should pay a very large proportion of the cost of such works. The question is, whether we are in a sufficiently advanced state to justify the Government in handing over to Shire Councils the large sums of money that would be required to carry out any general system of irrigation. I think not; but I think it would be a very good thing if the Government were relieved of a great deal of the work now thrown upon them. I think, for instance, that the water supply to country towns ought to be carried out by the local Municipalities, and that the Government should be relieved from the duty of carrying them out.

1118. *President.*] That cannot very well be done until there is an extended system of local government? I suppose not, but I think it is high time something of the kind were done.

System of levying rates.

1119. *Mr. Murray.*] Is it not possible to adopt such a system as they have in Ireland, where they levy a rate in proportion to the extent to which the land is improved by draining or the conservation of water? That is all very well with regard to drainage, but I do not think you could conserve water to any extent here. In Ireland there are no works nor any local bodies entrusted with the duties of conserving water in the country districts. I think the population is too scant to warrant the undertaking of any large works for that purpose—the time has not arrived for it, in my opinion.

Water conserving scheme.

Velocity and discharge of rivers.

1120. You stated that we had in the plans before us sufficient data upon which to calculate the velocity of the rivers: is the velocity not affected very much by the quantity of water that passes down the river-bed, and by the tortuous or straight course of the rivers, as well as by the levels? If you want to calculate the discharge, you would of course select a suitable part of the river where the channel is tolerably uniform and straight, and then taking the differences of level at two points you can calculate the mean discharge at those points, and you know it must be pretty much the same both above and below unless there are some large tributaries flowing in between these places. An Adelaide gentleman who reported on the lower Murray adopted a very original method of calculating the difference of levels. He found that the water travelled at a certain velocity in one part, and he computed the difference of level from the velocity of the water, which was of course absurd, as although the velocity would vary with the state of the river in times of flood, and would therefore, if adopted as the basis of calculation, give different results, the actual difference of level must remain constant. But I have had all the rivers absolutely levelled. We levelled from Albury to the junction of the Darling on the Murray. We levelled across from Albury to Wagga by the road; we levelled from Wagga down to the junction of the Murrumbidgee, and we got the railway levels from Melbourne to Albury, and from Wagga to Albury to Sydney, and again we got the levels from Echuca to Melbourne, so that we had several checks.

Levels of Darling, Murray, and Murrumbidgee.

1121. Have we those sections? I do not know, but they could be supplied if you have not.

1122. But you do not think we are ripe for such a system as has been adopted in Victoria? Well, I do not know that it has been adopted in Victoria.

1123. Oh yes it has? Well, our Colony is so large and the population so scant, that I think it would be better to make a beginning with the towns by making them provide their own local water-works.

Effect of improvement of water supply.

1124. *Mr. M'Mordie.*] Do you not think that if something were done to improve the water supply in the back country an increase of population would likely follow? I do not know. A great deal would depend on the amount of money voted every year for immigration. I think the principal advantage of improving the water supply in the back country would be to the squatters and others who are using the land for pastoral purposes. They do not however want a great supply of water. I do not know whether that part of the country is fit for agriculture—I am inclined to think that it is not.

1125. *President.*] But if by a system of water conservation it could be shown that that part of the country is more fitted for agriculture than it is supposed to be now, it would increase the stream of population in that direction? Well, it might; and if you conserve the water at the heads of the rivers, you could easily understand how even a very large reservoir would make very little show on the rivers in times of drought. The project of constructing reservoirs would be such a gigantic one that I do not think we could undertake it in our present circumstances. Just consider the channel of the Murray from Albury down, and suppose that had to be filled in a dry season sufficiently high to throw the water over the back country—see what a large reservoir would be required.

Diversion of water from rivers.

1126. But I do not mean that the water should be sent down the channel of the river, but that it should be taken from the river by means of canals? Then you would have to go into an expensive system of canals. It may be that the channel of the river would be the best canal to use.

1127. It may be, but in some cases it would lie too low? Well, I think that works of that kind on any large scale would entail an enormous cost.

Mr. E. O. Moriarty. 28 Aug., 1884.

1128. *Mr. Townsend.*] Have you noticed any scouring away of the rivers? Of course there is a certain alteration going on in all the beds of the rivers. We often find trees falling down, but I do not think that is of much importance.

Erosion and alteration of the river beds.

1129. Have you noticed any distinct alteration of channel during excessive floods? No; occasionally, where there is a long promontory with a very narrow neck I have known the river to make its way through, but generally speaking the river keeps to its bank.

1130. I was referring more particularly to the Darling, and to the observations your officers have been making on that river? I have never been on the Darling, but I do not think the matter you speak of is of very serious importance.

Railway embankments.

1131. *Mr. Donkin.*] Could we not make use of the same plan which has been adopted in Queensland, to utilize railway embankments for the conservation of water? If I had anything to do with the railway I should not allow you to make a dam of an embankment. Suppose the embankment were to be washed away and the train wrecked. That is a very foolish thing to do, in my opinion. I do not think you would get Mr. Whitton to sanction the use of his railway embankments for dams.

Use of anabranches.

1132. I think you said that the only way in which you thought water could be conserved, or at least distributed, was by making use of the anabranches? I think the first thing that should be done is to utilize all the anabranches as distributing channels.

Yanko Creek.

1133. For instance, as Yanko Creek carries the water from the Murrumbidgee? Yes. There are several channels, some leading into lakes on the Darling; they might be extensively used I think, and the cost would not be very great, because there would be no difficulty in constructing weirs in the rivers with locks for the vessels to pass.

Cost of impounding of water.

1134. Do you think that on a large scale the impounding of the waters at the head of rivers would not be a financial success at the present time? I am certain it would not—the cost would be something enormous. See what we have to pay for a single dam for the Sydney water supply.

1135. Half a million, is it not? Yes, and it is a dam constructed in a safe position, where there is no danger of a flood hurting it; but if you construct a dam across a river, you would have an enormous body of water to deal with, and you would require solid masonry.

Cost of labour in India.

1136. Do you know the difference in cost between embankments and chanel cuttings with regard to India and this country? I think in India the cost is about 1½d. or 2d. a yard, whereas the canal cuttings for the Sydney water supply cost about 2s. 11d. or 3s. per yard, or about ten or twelve times as much as in India. I believe that in India the proportion of the population is about 600 to the square mile. Here we have about 0·6 square mile to the inhabitant, or something like that. I should like to mention one thing, namely, that I think we are going to work in the right way in what we are doing towards clearing the river-beds of the snags. Whatever is to be done in these rivers should not be attempted until the natural channel is clear, and you could not clear them if you raised the water against yourselves. That we are doing now and have been doing for many years. We find that on the Darling the cost of clearing is somewhere about £45 a mile, including the pulling up and burning of the snags. On the Murray and Murrumbidgee the cost varies from £45 to £60 per mile, according to the locality. In some places there was a network of timber when we commenced operations. This is the first work that must be undertaken in any attempt to improve our rivers.

Clearing of river-beds of the snags.

1137. *Mr. Murray.*] How many miles in the year can you clear? We do about 12 miles a month on the Darling, and on the Murrumbidgee which is very heavily timbered, we do about 5 miles a month.

1138. *Mr. Barton.*] And are you clearing the timber from the banks so that it will not fall into the river? No, only where the timber is likely to fall in immediately.

1139. *President.*] And the trees that you pull down, do you leave them on the bank? We stack them on the bank, and when they are dry we burn them. On two or three occasions the piles of timber have been swept back into the river by unexpected floods, but we find that it is no use trying to burn timber until it has had the December sun upon it.

The rivers as feeders to railways.

1140. That work has reference principally to the navigation of the river, but it would not apply so much to irrigation purposes? No, but I think the matter should be considered in regard to navigation as well as irrigation. I should not like to see the rivers blocked for the purposes of navigation, because they are certain to be good feeders to the railways.

1141. The snagging is principally to ensure future navigation of the rivers? Yes.

1142. *Mr. Donkin.*] How do you find out the position of the snags? We can see them.

Clearing of snags by steam winch.

1143. Do you take them all out from the river-beds? Yes; we have a steam winch in a barge, and we make the tackling fast to a standing tree and one end of the fall fast to the log in the river. Then we bring the other end of the fall to the steam winch on the barge, and pull the log on to the river bank, where it is left to dry, and is ultimately burned.

Effect of the clearing on navigation.

1144. Then, as a matter of fact, until the river was cleared to some extent navigation was almost impracticable in the Murrumbidgee and Murray? It was, except at a very high state of the river, but since we have been at work we find that vessels can go up the river with 3 or 4 feet less water in it than than they used to be able to do in times past. They can also travel at night, which they were unable to do before.

1145. *President.*] The Murray is snagged for nearly its whole length, is it not? I do not think it has been entirely done, but a very large portion of it has. We have ceased our operations on the Murray, and are confining our attention to the Murrumbidgee and the Darling.

1146. But the Murrumbidgee and the Darling have been roughly snagged before, have they not, because steamers have gone up them for a long time? Yes, but they used to go up when the river was in flood. The rivers have not been snagged throughout, but they have been greatly improved in most of the bad places.

Rock impediments in the Darling.

1147. *Mr. Barton.*] Are there any rock impediments in the way of navigation in the Darling that could be removed at no very considerable expense? There are some rocky bars which we purpose removing. We have had them surveyed, and all the details of the work ready to commence.

1148. *President.*] The surveys have been made by officers in your Department? Yes, they have been made under my Department.

THURSDAY,

THURSDAY, 4 SEPTEMBER, 1884.

Present.—

Mr. BARTON, M.P., | Mr. GIPPS, C.E.,
Mr. DONKIN, J.P., | Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E., | Mr. MURRAY, M.P.,
Mr. M'MORDIE, B.E.

W. J. LYNE, Esq., M.P., President, in the Chair.

Mr. Wm. Christopher Bennett called in and examined:—

1149. *President.*] You are Commissioner for Roads and a civil engineer? Yes.

1150. You have made the question of water supply in this Colony a study, have you not? I have given it a good deal of attention. The supply from rivers has hardly formed part of my duty, but the supply from tanks and wells has. Mr. W. C. Bennett. 4 Sept., 1884.

1151. But you have taken great interest in the question? Yes.

1152. Have you not written some papers or some reports in reference to water supply for certain parts of the country? No, I do not think I ever wrote anything more than ordinary minutes with reference to tanks and wells, but eighteen years ago I gave some evidence before the Deniliquin and Moama Railway Committee, which evidence is published in the Votes and Proceedings of Parliament. (*Appendix* G 1.)

1153. In your Department you have had a good deal to do with the construction of tanks, I think, have you not? Yes, I have.

1154. Have you had anything to do with the sinking of wells in any part of the country? Yes, and we have still, but not artesian wells.

1155. Wells for what purpose? Ordinary wells for water supply on stock routes.

1156. Have you had any experience outside the Colony on the water question? Yes, all my early days were spent in works connected with water, drainage of rivers, the improvement of navigation, and mill-power, in Ireland. I was brought up in the Department of Public Works, and was there seven years. Then I had some work to do in connection with the navigation of the Magdalena River in South America. I was sent there on the recommendation of Sir Harry Jones, who was Chairman of the Commission in Ireland. After that I was offered sole charge of the English portion of the international survey of the Darien ship canal. I went out there to take charge on the Pacific side, and completed the work entrusted to me.

1157. Have you studied the river systems of this Colony? Yes, I have given the subject a good deal of attention, but not officially.

1158. Which systems in particular? I cannot say that I have given attention to one more than another, but perhaps the one that I thought most suited for the purpose was the Murray.

1159. Have you ever been to the head of the Murray? No, not to the head of it; I have been up as far as Maracket.

1160. From Albury upwards do you consider it would be possible to conserve or divert any quantity of water? I think it would be possible to divert a considerable quantity of water above Maracket. Diversion of water from the Murray.

1161. In what direction? Well, the exact mode of doing it would of course be determined by the levels; it would have to be done by a canal.

1162. Would you put a dam or a weir across the river? Oh yes.

1163. And in which direction would you divert the water? If the fall would admit, I would take it from the summit of the Murray to near the Billabong, and water each side as far as the water allowed. Diversion to the Billabong by canal and tunnel.

1164. Conveying it, when you got it in that direction, by a canal? Yes; it is possible, in fact certain, that you would have to make a tunnel. It might be more expensive than it is worth, but I do not think so.

1165. Supposing a scheme of that kind to be carried out, what would be approximately the extent of country that would be benefited? That would altogether depend on the available water. If you had water enough, you could irrigate the whole country down to Deniliquin. Extent of benefited country.

1166. I do not refer so much to irrigation as to water supply? Well you could supply water to the whole country, as far as the levels are concerned.

1167. That would be between the Billabong and the Murray? Yes.

1168. As far as Deniliquin? Yes, or possibly further.

1169. Did you observe any places on the Upper Murray where large quantities of water could be stored without diverting it in the way you speak of? It would be wrong to say that I had observed such places, but I have no doubt they exist and could be found by examination. Places for storage of water on the Upper Murray.

1170. Have you been to the head of the Murrumbidgee at all? Yes, I have been close to the head of the Murrumbidgee at Cooma.

1171. Are the features of that river similar to those of the Murray? No; the course of the Murrumbidgee is very much more circuitous, and the country is rougher, but still the Murrumbidgee might also be worth examination—that is instrumental examination. Of course no man can speak with any degree of accuracy until the instruments have been over the country. Features of the Murrumbidgee.

1172. Do you know of any other point on the Murray lower down, nearer Albury, where you are of opinion that water might be diverted? Mr. Gordon was speaking to me of some places at Tuppall, and I have no doubt that what he said was right, but a difficulty that occurs to me in dealing with the lower part of the river is, that unless you have an expensive movable dam, either automatic or otherwise, an ordinary weir will induce floods, as well as cause great expense in securing the sides from scour. Difficulty of diverting water from the Murray near Albury.

1173. You say an ordinary weir will induce floods? Yes, by raising the level, if you have it high enough. I think it desirable, therefore, if possible, to take the water out of the river where you have rocky or hard foundations, as you have in the Upper Murray. At the same time I have no doubt that what Mr. Gordon says is the case,—a very inexpensive scheme could be devised at Tuppall. Effect of weirs on floods. Diversion at Tuppall.

1174. Have you had any experience, or are you fully acquainted with the system of irrigation in India? As far as any man can be acquainted with a thing without seeing it, I am; but I have never seen it.

1175. Do you think the system carried out there would be at all applicable here? It is rather expensive; you would have to begin tentatively here, and on a smaller scale.

1176.

Mr. W. C. Bennett. 4 Sept., 1884.

1176. Do you think any general system of irrigation could be carried out here in a practicable and payable manner? It must be slow and tentative. It would be wrong to go rashly at it, but ultimately I have no doubt it will be indispensable to the profitable occupation of the country.

Irrigation. Rainfall.

1177. Do you think the rainfall of the Colony is sufficient to irrigate to any large extent? Not to irrigate the whole country broadly, but parts.

1178. But to any appreciable extent? Yes, I do; and you could greatly increase the extent by means of reservoirs if you found it pay, as I have no doubt it would.

1179. Have you been inland on the Darling at all? No.

The Darling country.

1180. Do you know much of the Darling? I never saw the Darling, except at Wentworth, but I know tolerably well, as far as a man can without seeing for himself, what the country is like, from the reports of officers, and from having works done there.

Wells.

1181. In your Department, has the sinking of wells in the far western country come much under your notice? Yes, ordinary wells—not artesian wells.

1182. Wells for stock purposes on travelling stock routes? Yes

Underground supply.

1183. And what is your opinion in reference to the underground supply of water obtainable in that part of the country—do you think there is an inexhaustible supply? Oh no.

1184. In any wells that you have sunk, have you any idea of the quantity of water? Like any other well that you sink into a permeable stratum, the well forms a crater round it, and the base of that will be in proportion to the depth of the well and the quantity drawn away from it.

1185. And have any wells that have come within your knowledge been tested to their utmost? A great many of them; we frequently test them to exhaustion.

1186. And they produce a good supply of water? They produce enough for the purpose required, but not an inexhaustible supply by any means.

Water conservation and distribution by Government or local bodies.

1187. In carrying out a system of water conservation and distribution, do you consider that it should be done by the Government in the first instance, or by local bodies? That depends on who may have to pay for it. If you tax the local people, I think they ought to have some voice in the works.

1188. But do you consider that it is possible or practicable to carry out any system before the Colony has been divided under a system of local government? Well, the purposes are so very distinct that even in England they find it necessary to separate the dealing with rivers from the ordinary local government, and they generally now have a body to deal with each catchment, entirely irrespective of other local subdivisions.

Water Trusts.

1189. *Mr. Gipps.*] They call them Trusts, do they not? Yes, Water Trusts; and they have sole control over each catchment. It would be very awkward if one-half of the river were under the control of one person, and another part under the control of another person.

1190 *President.*] That would then be carrying out the scheme by local bodies? Yes, by extended local bodies.

1191. It would be by the general government, irrespective of local government? There would have to be a large amount of general government intervention in the first instance, at all events, I think.

The water supply question with regard to local government.

1192. Then are you of opinion that any general system or scheme for the Colony of New South Wales could be carried out before the Colony has been subdivided, as Victoria has been, into local Shires and Boroughs? I do not think there is any connection between the two things at all; I think the water supply is so important and so different that it must be disconnected from any merely local government. Whatever body is to deal with a river must have control over it from its source to the point at which your irrigation operations commence.

1193. That would be, I presume, for the purpose of dealing with the watershed right through, so that no other interest would come in? Yes; but you will find interests enough arising in any mode of dealing with the subject.

Resumption of land above the dams.

1194. In making weirs or dams across the heads of any rivers where a large quantity of water is thrown back, do you consider it would be wise to resume the land above that point where it would be liable to flood? I think that would be unnecessary. You could make the barrage so as to prevent floods.

1195. But if you are going to conserve any large quantity of water I mean? If you are going to make anything permanent, such as a reservoir, of course you must resume the land.

1196. The whole country that would be affected? No, only the portion submerged.

1197. *Mr. Donkin.*] Do you know the Billabong Creek, that is where the Yanko cutting is made? Yes, I do.

Diversion into the Billabong.

1198. Was it your suggestion that the weir should be made at Maracket, above Albury, on the Murray, to divert the water into the Billabong? No, to divert the water into the Billabong at Ten-mile Creek. I did not suggest any particular point—I suggested that the country should be examined in order to find the best point.

Position of the Billabong.

1199. The main Billabong is about midway between the Murray and the Murrumbidgee? Yes, nearly on the summit.

1200. But the Murrumbidgee is not sufficient to keep it in stream? The Murrumbidgee has access to it only at certain periods. The Billabong occupies with respect to these two rivers a similar position to that which the Ganges Canal occupies between the Ganges and the Jumna.

1201. Do you not think the water of the Murray could be diverted into the Billabong? I have said so.

Height of weirs.

1202. You were speaking of weirs across the river being automatic—what height would you advise? That would depend altogether on the circumstances of the case, the quantity of water you wanted to divert, the country it was to be distributed over, whether it would be worth while to make a large weir in order to save excavation, and fifty other considerations.

1203. Did you take into account at Cooma the quantity of snow-water passing down? I did not see any. At that time there was very little water in the Murrumbidgee.

Action of snow.

1204. The snow affects the discharge? Yes, and still more on the Murray. The snow acts as a reservoir.

1205. You said the tanks and wells were under your direction? Partially—I have not sole control.

Utility of tanks or wells.

1206. Which do you prefer as a means of providing water for stock, tanks or wells? The tank is best in some places, the well in others. I think that on the other side of the Darling wells are the best. It all depends on rainfall and whether there is water. At a depth of 150 feet you can get salt water almost anywhere, but that of course will not do for stock.

Success of irrigation.

1207. Do you think irrigation in New South Wales would ever be a financial success? Not *per se* at first,

Mr. W. C. Bennett. 4 Sept., 1884.

first, but it would be in this way: that it would enable the squatters or the occupants of the land, whether squatters or selectors, during periods of drought, to have lucerne paddocks to prevent their stock from starving. That is the first use I would look to. After that you would find the people gradually extending its use to the limit of the water, which is the only limit. I have no doubt they would ultimately find it to their advantage to put reservoirs at the heads of the rivers; and if you look at the evidence given before the Hunter River Flood Commission, of which I was a member, you will find that a great many of my questions had reference to the establishment of reservoirs at the head of the river, for the immediate receipt and gradual discharge of the water, thereby mitigating the floods. There was a large scheme proposed by Mr. Ellett for the Ohio, but I found just at that time that flood after flood came into the Hunter River, so that it was evident that the amount of reservoirage that was necessary to have any appreciable effect would be almost impossible to provide. The converse of that, however—the necessity for providing water by means of reservoirs in dry seasons—is altogether another question.

Hunter River Flood Commission.

1208. You think then that in any scheme for the conservation of water in this Colony each catchment area should be taken separately? Yes, that will be admitted by any one.

Conservations in each catchment area.

1209. What means do you adopt for sinking wells? The ordinary mining prospector's shaft. We had a boring apparatus many years ago, and sank wells to a depth of 200 feet, but we found that the ordinary prospecting shaft was the best. The transport of the boring apparatus and all water required our having a lot of men directly in our employment, and we found that the rough miner's shaft serves the purpose much better.

Apparatus for sinking wells.

1210. *Mr. Barton.*] Is that evidence you spoke of as taken by the Hunter River Commission available? Yes, you can get it from the Government Printer. It is only by carefully reading my questions that you will find the drift of them.

1211. *Mr. M'Mordie.*] What districts would you recommend for the preliminary survey in order to see what can be done in the way of water conservation? You might take the Murray, above Albury. I would level up the country, beginning where there was a reasonable fall, and trying for a narrow place in the range. The Murrumbidgee ought also to be examined, at a point perhaps a little above Queanbeyan, though I do not know the place sufficiently to localize it. It should, however, be at a height sufficient to enable you to convey water across to Cootamundra if it is possible; though I do not assert that it is possible. You might also examine the Macquarie, but the quantity of water in that river is so small as to be hardly worth the trouble. A subsidiary supply to the Murrumbidgee might be got from the Lachlan. The Peel and the M'Donald Rivers, perhaps also the Severn, and indeed the heads of all our rivers, might be examined.

Districts to be first surveyed.

1212. In sinking tanks for stock purposes, what slopes have you adopted for the excavation? 1½ to 1.

Slopes of tanks.

1213. Have such slopes been found too steep to stand, and unsuitable for the purpose? I have not heard any complaints where proper care has been taken. In some places where the water was let in or came in with a rush there has been some little damage, but that has been beyond our control.

1214. Would it on general grounds be objectionable to adopt flatter slopes, as 3 to 1 or 5 to 1? Yes, it would, because the evaporation is so great. Mr. Greig, of Fowler & Co., found great fault with our slopes, because they would not permit of his machinery being used to advantage. I told him we would adopt any slopes he wished, so that he might try what he could do, and he is now excavating a tank up near Nymagee. But what he then proposed was to leave the two ends open, with embankments at the side, so that all the spoil is lost.

1215. Would you approve of planting trees on embankments made for holding in water? Certainly not.

Trees on embankments.

1216. You would not think that an improvement? No.

1217. *Mr. Franklin.*] Are you acquainted with the river diversion carried out in Victoria by Mr. Gordon? Mr. Gordon sent me his reports; that is all I know about it, excepting that I have also had conversations with him on the subject.

1218. You do not think it would be advisable to plant trees around large dams in the interior? Not in dams which are intended to hold water, because their roots would penetrate the bank and make leakage places.

1219. In India they plant trees very extensively? But the banks there are not intended to hold water, and the trees are planted for shade.

1220. On the canal banks they are still planting trees? They may, but are the banks not merely spoil banks?—In that case the trees are used to prevent evaporation, and the banks are not made to hold water.

1221. *Mr. Murray.*] Have you any sections of the wells sunk by your Department? No; we have on record all the depths and the kind of material, but not the sections, because there was no use in preparing them. We can prepare them, however, if it is desired.

Records of depth and material of wells.

1222. You can show the strata if necessary? Yes.

1223. And plans showing the position of different wells? Yes, but we have not connected them by levels.

1224. Do they give a record of the strata passed through? Yes.

1225. And what wells contain fresh and what salt water? Yes, we can compile all that information by searching the records.

1226. Have you made any report recommending the best system of conserving water at the heads of our rivers or otherwise? No, I have never been officially called upon to do so.

1227. You think it would be necessary to have a complete examination of the country and a survey made before any system could be decided upon? Yes, I think that the first thing to do is to measure the water—the minimum supplies of water all over the country. Most valuable information may be obtained in that way. The next thing would be to show on a good plan the lines of equal rainfall, and then to compile all the railway levels and road levels. Then you would be in a better position to feel your way as to the course that should be taken.

Necessity of examining the country.

1228. Would there be any difficulty in establishing observations? No, I do not think there would; but whatever difficulty there may be it must be overcome.

Difficulty of observations.

1229. Could not your superintendents undertake that work? No; I think they have too much to do already, and many are not fitted for such delicate observation.

1230. *Mr. Gipps.*] How do you think the water supply of the different river systems could be most profitably applied—to irrigation, motive power, or navigation? In a country where coal is so cheap as it is here, I think motive power is out of the question, and as to navigation, if good permanent navigation can be established I say yes; but navigation in our rivers is so desultory and difficult. It is possible

Most profitable application of the river waters.

Mr. W. C. Bennett. 4 Sept., 1884.

one year and for three years it is impossible. A railway will carry much more surely and nearly as cheaply. It would be a different matter if you had large quantities of heavy material to transport, such as coal or iron ore, but for anything which can be carried by rail, railways are the best. I think the proper function of rivers here is to supply water.

Diversion of Murrumbidgee to Lake George.

1231. Do you think it would be possible to divert the Murrumbidgee at Basin Creek, 2,600 feet to the level of (say) Lake George, 2,300 feet? I do not, because the country around Lake George is not precipitous, but rather sloping.

1232. If you take a point high enough on the Murrumbidgee it could be done: if it could be done would you recommend it? No, I do not think I would. I do not see of what advantage it would be. It might be possible to do it, but the question is, could you get a sufficiently *deep* supply in Lake George, because we know it is dry sometimes. Whatever reservoir might be established should be very deep indeed, so as to expose as little of the surface as possible to evaporation.

1233. Could it not be done by making two impounding banks? It is possible. Of course it is a matter for investigation. I should prefer some lateral valleys of the rivers.

Cross sections of Darling.

1234. Have you any cross sections of the Darling about Bourke? We have them at Bourke and Brewarrina for bridges—that is all.

1235. *Mr. Barton.*] Have you none above Brewarrina? We have at Walgett, but I do not call the river the Darling there.

1236. *Mr. Gipps.*] Have you ever estimated the quantity of the water flowing down the river at Bourke? No.

Use of wind-power.

1237. Do you think it would be advisable to use wind-power as much as possible? Yes.

1238. In which way—directly, or by means of compressed air? It depends on what you want it for.

1239. Do you think the wind in the interior would be regular enough to be depended upon absolutely? It might if you had a sufficiently large reservoir. For instance, we are putting up a windmill at Lignum Hut, on the road from Hay to Wilcannia. A larger reservoir is required there than elsewhere, but it would be very expensive to apply wind-power—that is, by the compression of air—so as to ensure permanence.

1240. You do not think it would be advisable? Not commercially advisable.

The question of navigation.

1241. *Mr. M'Mordie.*] I understand from your evidence that you consider the question of river navigation secondary to that of water supply? Entirely secondary. The navigation of the rivers will be superseded in a few years by railways. The money expended on our rivers has been attended with valuable results, because hitherto there was no other means of getting produce to market; but in future I think that the rivers will be utilized for the purpose of water supply, and in producing something to transport rather than in transporting it.

1242. If one or the other is to be sacrificed you would sacrifice navigation? Yes.

1243. *President.*] But throwing weirs across rivers and also locking them would not prevent navigation? Locking, of course, makes provision for navigation; but a weir must stop navigation, if it is to be efficient. On the rivers in America, especially where there is any large amount of water, there is an opening for navigation, and boats shoot the passage; but here you have not water enough.

The action of floods on locks and river courses.

1244. But with a lock, navigation could still be kept up? Yes; but there is one matter in connection with our rivers which people have not considered, and that is the great range of floods in the rivers. If you have a lock that is of any use in ordinary weather, unless you go to great expense in building walls above flood-level, they must be submerged during floods and be exposed to injury. You might have a new river-course made by the first flood. It would be necessary to put locks and weirs at particular points where you could dominate the whole flood-line, otherwise you would have—what I have no doubt gentlemen acquainted with our rivers have seen on a small scale—your dam outflanked.

1245. Would not the same thing occur in India? No; the flood range is not so great in India. The flood operates to a greater depth in the sandy beds of the rivers, but the difference between the high and low waters is not so great, and the locks in India are all on canals or branches of canals.

Diversion of water from Murray above Albury.

1246. I think I understood you to say that it would be practicable to divert a portion of the Murray River from somewhere above Albury, near Maracket? I do not say above Maracket, but wherever the levels show it to be desirable.

1247. And take it down through the dry country between the Murray and the Murrumbidgee? Yes.

Its effect on the necessity of tanks.

1248. If that were done, a system of tanks in the neighbourhood of the canal by which the water is conveyed might easily be made, I presume, and the water conveyed into them? I think it would hardly be necessary.

1249. But still it would be possible? It would be possible.

1250. At the present time there are numerous tanks being made, and many others have been applied for in that part of the country? There are, under a sort of protest from me that the other thing would be better, which protest was to a certain extent overruled.

1251. But if the water was conveyed from the Upper Murray to the neighbourhood of these tanks, a good supply could always be got by diverting a portion of the water from the canal? Yes, but if the water was in the canal you would not want it in the tanks.

1252. But I am supposing the canal a few miles away from the tanks and that the levels are favourable? Oh yes.

Diversion from the Murrumbidgee.

1253. I think you also suggested that the water from the Murrumbidgee might be diverted and taken through that dry country somewhere in the neighbourhood of Cootamundra and down towards Temora? Yes, the Upper Murrumbidgee.

1254. And on I suppose towards the junction with the lower Murrumbidgee, or to the junction with the Lachlan? As far as the water would carry it. It is impossible to say, because there might not be water enough to go half the way. If there was much use for it, it would not.

Supply from the Abercrombie ranges.

1255. I think you said also that a supply of water might be obtained from the heads of the Lachlan and along that river? Yes; in the Abercrombie ranges suitable places might be found for reservoirs or even for living water.

1256. And the same might be done, I think you said, to a limited extent, at the head of the Macquarie? A very limited extent. The Fish River is very small.

Effect of any such scheme on the dry country

1257. Supposing that a scheme of that kind were carried out, would it not to your knowledge open up a large extent of country now very dry? It would not open it up, because it is opened up already.

1258. But it would enable it to be better utilized? Certainly; but there are gentlemen here who can speak on that subject much better than I can.

1259.

Mr. W. C. Bennett.

4 Sept., 1884.

1259. It would also save a large expenditure now being incurred for dams and tanks, would it not. It would.

1260. And the supply would be far more certain? Yes.

Desirability of establishing an example.

1261. Would you suggest or would you think it advisable that experiments should be made in any part of the country either in the way of diverting water or impounding water, for the purpose of showing the public generally the advantages to be derived? I would not call the bringing of a scheme of irrigation into operation an experiment, but I think an example of the sort would be desirable. But before anything is done the minimum quantity of water should be ascertained, and the obtaining of that information cannot be too soon begun, so that it may extend over the approaching summer.

Minimum quantity of water should be ascertained.

Possibility of a water conservation system.

1262. Then, to sum up the whole matter, you consider that it is not impossible or impracticable to carry out a system of water conservation and distribution throughout the Colony? I thought so eighteen years ago, and every year has strengthened my conviction.

Darling waters going to waste.

1263. *Mr. Donkin.*] Have you any practical suggestion to make as to dealing with the waters of the Darling which at present run to waste in the sea? It might be possible to utilize them by erecting movable weirs at the mouth of the tallywalkas. I hold with conserving water in every possible way.

Impounding water below Brewarrina.

1264. Do you think the water could be impounded to any extent in the river below Brewarrina without a scour taking place in its banks? If you had movable weirs you could. You should try and have the water in your reservoirs as deep as possible, in order to present as little surface as possible and thus save loss by evaporation.

Evaporation.

1265. *Mr. Barton.*] Have you ever obtained any evidence as to the amount of evaporation which takes place in the western or north-western district? No, but I have very good evidence as to the evaporation in Sydney. When the Sydney Water Commission was sitting, I wrote to a friend in India and received the information that the allowance for evaporation was 6 feet per annum in the moist climate of Lower Bengal, and that probably the amount was larger in the country above. Adopting that as a basis, I made a calculation with reference to the Botany water supply, and came to the conclusion that after making all the improvements possible they could only count on 3¼ million gallons of water per day. That is about the minimum amount they get now, and my calculation was made fourteen years ago.

Material for weirs.

1266. *Mr. Murray.*] What should the movable weirs be constructed of? Timber or iron.

1267. I noticed that the flood-gates at Maitland had given way through being destroyed by white ants? Those constructive difficulties must be overcome. Iron, of course, is exposed to oxidation.

Diagrams of weirs.

1268. *Mr. Donkin.*] Have you any diagrams of weirs you could lend the Commission? There are some papers in the minutes of the proceedings of the Institute containing diagrams, and I think I have some in other papers.

The Yanko cutting.

1269. *President.*] At the present time there is an agitation to deepen the cutting from the Murrumbidgee to the Yanko: what is your opinion as to the possibility or the advisability of placing a weir across the Murrumbidgee below that cutting, and by that means diverting the water down the Yanko? It is to a great extent a question of cost. Provision should be made for floods, by removal of the weir or otherwise.

1270. But, provided it is not too costly, do you not think that would be a very good way to show on a small scale to the public the advisableness of placing weirs across rivers? Hardly so well as one in the Murray, because you could not by any weir raise the water above the surface of the country immediately at the Murrumbidgee; you might raise it a little above the country below, but I think the Upper Murray would be the best place at which to commence, because you would have complete command of the country there.

1271. But this is a case in which it is proposed to divert a portion of the Murrumbidgee water into the Yanko: I do not know whether it is quite settled that this shall be done, but I believe it is, and that being so, would it not be wise to place a weir in the Murrumbidgee and raise the water in that way—to do it on the Murray would involve great expense? Of the two weirs, the one at the Murray would be the cheaper.

Irrigation by steam pump.

1272. But there would have to be a tunnel? Yes, the collateral expenses would no doubt be greater. There is an interesting paper which I will get for you, written by Mr. Mair, of Groongal, who irrigated by means of a steam pump, and with very successful results. (*Appendix* G 2.)

The diversion into the Yanko.

1273. What I want to get at is this: as there is an agitation at the present time to divert a portion of the water of the Murrumbidgee to the Yanko, is it advisable that that should be done by means of a weir across the river, instead of having an intermittent supply by means of a cutting above? If you are prepared to go to the expense of a lock and so on, it would be advisable, but I do not think you would have a fair example of irrigation, because you cannot command the land. You asked whether it would be advisable as an example.

1274. I did not mean so much an example of irrigation as an example of diverting the main stream of the river? I think it would.

1275. In this instance, where the water is to be diverted down the Yanko intermittently, would it not be wise, as well as furnish a good example, to place a weir across the river and divert a constant supply of water down the Yanko? It might be.

1276. *Mr. Donkin.*] Exactly what has been carried out in Victoria by Mr. Gordon? Yes, but not by movable weirs.

1277. But why should not this be a fixed weir? Because the river is liable to flood. Mr. Gordon has, I believe, made the weirs where there is not much flood-water. They are cheap and inexpensive things in small watercourses.

1278. *Mr. Franklin.*] Would not an ordinary stone weir with movable shutters keep a constant fall at the back if the navigation was not a matter of great consideration? Yes, while the navigation was stopped.

Opening of weirs in India.

1279. Some weirs in India have openings to the full depth, and quite equal to some of our rivers in width? Yes, those openings have been in existence for years, and the difficulty has been how to manage them. The most successful automatic system is to a great extent a modification of the old bear-trap sluice.

Self-acting sluices.

1280. In those places where there is much soakage, would it not be possible to construct stone weirs of the same character as those used in India? I think it would be desirable to keep the tallywalkas and back-water full, and to have self-acting sluices, which would prevent the water from going back into the river when the river fell.

Prevention of great floods.

1281. And if, after examination, a good system could be adopted for the conservation of the upper watershed, would it not be possible by this means to prevent the great floods that take place in the north-western district?

Mr. W. C. Bennett. 4 Sept., 1884.

district? I am afraid the rainfall is so great, in the case of the Hunter particularly, that no possible amount of reservoirage would have the slightest influence on the floods. The reservoirs would be kept full in anticipation of a dry season, and then a flood would come. If you knew when the floods would occur it might be done with advantage.

1282. *Mr. Gipps.*] Would that apply to the Darling as well as to the Hunter? The Darling is longer, but its flood-waters would to a great extent have the same conditions.

1283. *Mr. Franklin.*] It has been conceived that by damming the smaller tributaries of the Darling we could convey water into creeks which perhaps would not be influenced by storms and floods? That is what I have been pointing out—that the effect of the flood would be hardly appreciable; it would to a certain extent, but not to an extent worth considering.

1284. If on an examination of the upper part of the watershed, and by making levels from one watershed to another, we find that water can be conveyed into natural depressions and stored, those outlets would be of very great service? Yes, if stored in a very dry season, it would be very desirable.

Necessity for survey and ascertaining the discharge of the rivers.

1285. *Mr. Barton.*] From your experience you think it necessary for a Commission of this sort, before acting in any way, to make a preliminary survey of the heads of the various rivers? Well, the surveys that exist in the Surveyor-General's Department would give you almost all the information you require. But what I think is particularly required is the measurement of the minimum water discharges. Ascertain that accurately, and also put down on the maps the line of equal rainfall, so that you may know what rainfall to expect from a certain area of country. If you call that a survey, I think such a survey is indispensable and the first thing that should be done.

Division of labour between the members of the Commission.

1286. Can you give us your advice as to the best plan for the Commission to adopt to obtain those surveys? I will give you a case in point. When the Water Supply Commission was first appointed I was not a member, but it was considered desirable that I should be, and accordingly without any solicitation on my part I was appointed. I found that the gentlemen of the Commission had been going about the country all together, and that great differences of opinion prevailed as to what ought to be done. At the very first meeting I attended I suggested that the work should be divided among the members of the Commission, that one should have one thing to do, another another thing, and so on, and that the result of each man's labour should be submitted to the Commission and talked over. That suggestion was adopted, and it is what I would recommend to you. I think a division of labour in such matters is by far the best plan.

Appointment of executive officers.

1287. Do you think the work would be better done by Members of the Commission than by officers appointed for the purpose? In the case of the Commission I have spoken of, two or three of the members had a large staff at their disposal—for instance, Mr. Moriarty, Mr. Adams, and myself. If you have not a staff at your disposal you would certainly want one or two executive officers.

1288. *Mr. Gipps.*] Those officers would carry out the surveys the Commissioners would require, after examination of the country? Yes. The examination of the country would eliminate all but two or three projects that are worthy of particular examination, and you could have them examined by your officers. And, if I might make the suggestion, a progress report showing the result of each examination after it was made should be furnished. It would show the public that something was being done.

1289. *Mr. Donkin.*] I suppose that in making a flying survey barometric heights would be sufficient? Barometric heights will enable you to judge where the surveys should be made.

Mr. John Wright, C.E., called in and examined:—

Mr. J. Wright, C.E. 4 Sept., 1884.

1290. *President.*] What is your name and profession? John Wright; I am a civil engineer.

1291. Have you had experience as a civil engineer outside the Colony? Yes, in India and the United Kingdom.

1292. To any great extent? Well, in this particular class of engineering I have had considerable experience. I have travelled a great deal, and having been Instrumental Secretary for the Public Works Commission in India, I had opportunities such as few possess.

1293. Is that long since? About eighteen years ago.

1294. What Commission was it? A Public Works Commission.

1295. Had that Commission much to do with the question of water conservation? It was a Commission on Public Works in general, and it dealt with water-works as part of its duty.

1296. You have read a paper before the Engineering Association of New South Wales on the subject of water conservation, have you not? Yes.

1297. Is this the paper (*Appendix* H)? Yes.

1298. The information contained in that paper has been obtained by you from personal observation in New South Wales, I understand? Yes, decidedly. I am almost a native of the Colony, and have taken a great interest in the question of its water supply ever since I have been able to take an interest in any matter whatever.

1299. You have been in the Colony many years, have you not? Yes, it is forty-four years since I came here first.

1300. Then did you go to India? No, to England.

1301. And from there you went to India? Yes, and from India to Victoria, and from Victoria to South Australia.

1302. Have you been over the western part of New South Wales? Yes, the whole of it; I have gone over the whole western and north-western portions of the Colony, taking the northern line as one boundary, the boundary of Queensland on one side and of South Australia on the other. I have been Consulting Engineer for the South Australian Pastoral Investment Association for the last ten years, and have carried out all their work for water conservation. That of course includes Queensland, South Australia, and portions of New South Wales north of the Darling.

1303. Then you have had every facility for obtaining information as to the possibility of procuring water by well-sinking? Yes.

1304. And also for conserving water by means of tanks? Yes.

1305. Will you give us what information you have with reference to well-sinking, first in the western part of the Colony? Yes, I could, but not from memory. I have been employed in so many cases that it would be impossible for me to name them in detail. I commenced, many years ago, taking notes and obtaining particulars

Mr. J. Wright, C.E.
4 Sept., 1884.

particulars as to well. Besides notes I have taken myself I have obtained information from others. I think I have supplied the Hydrogeological Society of England with notes of upwards of 3,000 tanks and wells.

1306. On what stations have you been employed sinking wells? On various properties; the Palartoo, Belama, Black Rock, Cudiginnie, and others.

1307. Are those in New South Wales or South Australia? South Australia. Coming over to the New South Wales border there are a number of blocks, the Cudiginnie blocks, which extend into New South Wales, coming close to Silverton on the soakage. The wells there are only a few feet deep. Wells at Cudiginnie.

1308. Can you give us, by reference to your field-books, or any papers that you have, particulars as to the wells that have been sunk? I could, but it would be an immense labour. If you mentioned any particular part I could supply you with the data.

1309. In the west and north-west parts of the Colony to what depth generally did you sink for water? Depth to water in the west and north-west of the Colony. Commencing on the Darling, at about Mount Murchison, and going north and west from there to Messrs. Crozier and Hughes' property—that is on the Lower Darling—the depth ranges from 60 to 90 feet; after that it gets down to 200 and 300 feet; that is, going towards the South Australian boundary of New South Wales.

1310. Then the further north you go the deeper the wells become? Yes, until you get to the Stony Desert, when it shallows again slowly.

1311. What is the nature of the strata that the water is found in? It is what is termed cretacea-gravel with a few shells in it. The depth we have never ascertained, because as soon as we get to the cretacea there is no necessity to go deeper; the water comes in in such volumes. Nature of strata cretacea-gravel.

1312. Is it artesian? No, I am not aware of any artesian supplies in Australia, excepting one or two. Artesian supplies.

1313. Where are they? One in Gippsland, and the other in Central Australia. I believe there are others, but those are the only ones I have seen.

1314. Is the water in the western country you have described generally good, or is it brackish? In some places it is good and in others it is slightly brackish, but I find that it is gradually improving. As you draw upon it it improves in quality. Quality of water.

1315. Have you had any experience to the north of New South Wales—in Queensland—to any extent? Experience in Queensland. Yes, from the Diamantina, down along the Paroo, Cooper's Creek, and the Narran, and all that way.

1316. And are the strata of the same nature as you have found in the north-west of New South Wales? Yes, in some places it is; you can scarcely see any marked difference—it is simply a difference in the alluvial deposit.

1317. And what bands do you generally sink through? Almost all sorts of Australian geological stratifications, many of them peculiar to Australia, commencing with the ordinary surface mould, and then passing through various kinds of clay, intermixed with marl, occasionally yellow sandstone, and other kinds of rocky schist. In some portions of the Diamantina country you find decomposed granite in small beds. On that account I advised the Hon. George Thorn two or three years ago to sink for wells in that part of the country, and a few months ago he succeeded in discovering water at a depth of about 70 feet. Strata. Depth to water. Mr. Sangar, one of the geological surveyors of South Australia, thought they would not reach water at a less depth than 500 feet, but water has been found all over that part of the country at 70 feet, and they are now going west. Mr. Beverley is going west to the South Australian border, and they are getting water there also. It rises on the central table-land, and when I was there, some seven weeks ago, they were getting water at a depth of 130 and 140 feet. I saw one of the water surveyors from South Australia, and he told me they had struck water further west, within 60 miles of the telegraph line, at 92 feet, so that the depth is getting low again. I have been engaged for numbers of gentlemen in that part of the country; I make surveys for dams, tanks, wells, and what not, but I can hardly give you the number of them.

1318. When the water is struck as you say, after going through various bands and beds, does it rise at all in the shaft? Yes and no. In some places it does, but in others it does not. Rise in the shaft.

1319. Then as a rule it is not artesian water? In a professional sense artesian water is water that rises above the surface and keeps up a good supply. An ordinary well is one in which you strike water and the water may rise but does not overflow.

1320. Where do you suppose the water you find in that part of the country comes from—is it simply surface drainage? Yes, from the actual rainfall. Source of the water.

1321. In the neighbourhood? I would not like to say in the neighbourhood, but when you consider I have travelled 120 miles in from 3 to 18 inches of water you can understand that there must be enormous bodies of water falling upon the surface there, and it cannot all run away. I proved conclusively years ago that it never reaches the sea.

1322. *Mr. Barton.*] Not above ground? No, it is impossible, because there is less water passes at the Murray mouth than passes Wentworth—that I proved by actual observation. Lieut. Gowlland and I made a survey of the Murray mouth, for the purpose of ascertaining the amount of water that flowed down, and we proved conclusively that less passes through the mouth of the river than flowed past Wentworth, and the only conclusion that it is possible to arrive at is that the water escapes underground. Water passing through the mouth of the Murray.

1323. But what I want to arrive at is this: there is a theory that the water found in the cretaceous formation to the north-west is, as a rule, water that comes from higher land in some direction, and I want to ascertain your opinion as to whether that is so or not? I think it comes from the rivers and watercourses. Messrs Crozier and Hughes asked me to go and see their properties on the northern bank of the Darling, with a view to conserving water. Being a Government officer at the time I could not go, but I sent a young man to take levels from the Darling right across to the boundary of their property, and along it as well, and we had the whole plotted out so that we had contour levels. We had then what I may call a block chart 90 miles long by from 30 to 60 miles wide. A well was sunk on the lower portion, and a series of wells were then sunk right through the property, going eastward, parallel with the river. Those wells, although they extended from 8 to 30 miles back from the river, were actually affected by the river, and the reduced level could be determined almost one from the other. A rise in the river caused a rise in the wells, not in proportion to the rise in the river, but still perceptible. The nearer the well was to the river the greater was the rise, and the further the well was from the river the less was the rise, proving conclusively that the underground supply of water was affected by the supply in the river. Source of water in the cretaceous formation. Height of water in the wells affected by stand of the river.

1324. As a matter of fact, that it came from the river? Yes.

Mr. J. Wright, C.E. 4 Sept., 1884.

1325. But that is not in the part of the Colony we have been speaking of—the north-western part? It would be in the north-west. It is only about 100 miles from the northern boundary of the Colony.

1326. Did I understand you to say it was on the Lower Darling? Well, you may call it the Lower Darling; it is between Menindie and Wentworth.

1327. But it is to the south of Wilcannia? Yes, slightly.

1328. And it is to the south of a point on the South Australian border, opposite Wilcannia? Yes, it is almost due south of the boundary of Queensland, South Australia, and New South Wales.

Formation the same as in the north.

1329. And is the formation there and the drift in which the water is found the same as it is in the north of the Colony? Sinking to a certain depth it is, to about 60 or 70 feet. The alluvium stratification is about the same. There is very little difference on the large flats, but when you get 70 or 80 miles down the Darling you encounter rock.

Occurrence of rock.

Shells *micobia*.

1330. And do you find the cretaceous formation lower down similar to that higher up? Yes. The shells *micobia* are the same beyond Milparinka as they are beyond Wentworth.

Wells in Deniliquin country.

1331. Have you had similar experience of the river affecting the wells northerly? No; but south of that I have, in the Deniliquin country—that is, including the Murray, the Edwards, the Murrumbidgee, and the Lachlan. I know that country well, and I know that the water in the wells there is affected by the water in the rivers.

Underground currents.

1332. In any well-sinking have you come upon an underground watercourse, or what appeared to be an underground watercourse? I have repeatedly tried if there was any drift, but only in one instance did I discover any. That was in the Gotha Paddock, Cobran, 35 miles from Deniliquin. There I found that on putting corks into a well they went, as it were, from the river Edwards towards the river Murray. In South Australia, in the limestone country, you strike immense streams, but where they lead to you cannot tell.

Streams in limestone country in S. A.

1333. In what part of South Australia is that? Taking the south-eastern area from the Victorian boundary, including Narracourt right down to Coorong and the sea boundary—the whole of the south-eastern portion of South Australia—and further on to Lake Hamilton and Streaky Bay, you can go into caverns as large as this room and there are underground currents alongside you. But a most remarkable feature in the Port Lincoln district is a spring where you can see fresh water bubbling up through the salt water, and can take a drink of fresh water from the sea when you are in a boat. At Kirkalla Station, towards Streaky Bay, they obtain water under very peculiar conditions. Some ten years ago, Mr. Linklater asked me to advise him about getting water. The rainfall there is very uncertain and limited, more so than on the Darling. I suggested to Mr. Linklater that he should sink wells, and he said he had tried and found them unsuitable. He had sunk down to the granite—the primary formation is very close to the surface there, being only some 60 or 70 feet down—but he could not get water. At last a miner suggested that they should drive and increase the area so as to get water by soakage. This was done, and I had a letter from Mr. Linklater some eighteen months ago informing me that he had succeeded in getting perfectly pure water in an almost unlimited supply.

Fresh water in the sea in Port Lincoln district.

Water supply at Kirkalla Station.

1334. *Mr. Barton.*] Is that on the coast? Yes, within 14 miles of the coast.

Source of the water in the limestone formation.

Dismal Swamp.

1335. *President.*] Referring to the water that you found in the formation near the Victorian border, have you any theory as to where that water comes from? Yes, decidedly. The formation there is limestone throughout. The Dismal Swamp has a very large rainfall. It is a large lagoon or lake as you might call it. The rainfall is conserved there, and it is from that source that the underground supplies in the south-east of South Australia are derived.

1336. That is not water that can be in any way traced to the rivers? No; at least, I do not think so. It could scarcely be traceable to the Murray, because the Murray is lower than it.

THURSDAY, 11 *SEPTEMBER*, 1884.

Present:—

MR. BARTON, M.P., | MR. GIPPS, C.E.,
MR. FRANKLIN, C.E., | MR. LYNE, M.P.,
MR. M'MORDIE, B.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. John Wright, C.E., called in and further examined:—

Mr. J. Wright, C.E. 11 Sept., 1884.

1337. *President.*] Are you ready to continue your evidence? Yes, but I think it would save time if I were to describe a few of the physical features of the rivers of the country, confining myself exclusively to New South Wales, as the Commission is for the purpose only of dealing with the interior of New South Wales.

1338. We should also like some information with reference to the Queensland rivers? Yes, the Queensland rivers also. Of course they would be the tributaries of the Darling. I think that course would save time, and assist you in putting leading questions to me.

Action of Darling waters on the Murray waters.

1339. Very well, give us all the information you can? Well, commencing with the Murray at the boundary of this Colony, and coming upwards, one peculiarity I may notice—though it is not peculiar to this Colony alone—is, that although the river Darling flows into the Murray during flood-time with a large increment of water, yet it actually does not raise the level of the Murray—it simply increases its velocity. In all recipient rivers the same thing occurs. This fact is borne out by the evidence of the leading hydraulic engineers. It must not be supposed that a rise in the Darling will raise the water in the Murray—it never has done so, and never will. Then taking the southern bank of the Murray on the Victorian side, it is high throughout, right up to Albury, whereas on the New South Wales side the bank is invariably low. In some places—as, for instance, between Moama and Echuca, the banks tend to about the same level; but when you get down to Tourangabbie the water appears to drain off towards Thule. The inclination of the surface then is northward. The Loddon is another case in which the waters which flow into the Murray do not increase the height of that river, though a large body of water flows into it. It however increases the velocity. Coming northward again to the Campaspie, which flows into the Murray below Echuca, the same thing occurs. Then we go on to where the Edwards flows out in that big swamp above Moira. In 1861, while

Banks of the Murray.

Effect of the Loddon and Campaspie on the Murray.

The Edwards.

Mr. J. Wright, C.E.

11 Sept., 1884.

while on furlough from India, I went from Echuca to Deniliquin by water, in order to determine how the water flowed out of the Murray into the Edwards. I found that it rose in a very large swamp almost the same as Moira, perhaps not to such a great extent, but with nearly the same depth of water. On that occasion I went, at the instance of Messrs. Desailly and G. S. Lang, and other gentlemen, to determine whether it was possible to divert the waters of the Murray into the Billabong. Nature has herself set the example, because the waters of the Edwards flow out of the Murray and into it again. I was not able to complete the surveys, but Lieut. Dawson, R.E., completed them, and proved conclusively that the water of the Murray could be diverted into the Billabong. The cost I was never able to ascertain, but I think it was given fully in the *Pastoral Times* or *Southern Cross*, about 1861 or 1862. That lowness of the New South Wales bank is a notable fact in connection with the watershed area of the Murray. It may not be uniform, but it is generally lower than the bank on the Victorian side; on the Victorian side the rivers of the Dividing Range fall towards the Murray, whereas on the New South Wales side the rivers fall away from the Murray. The natural watercourses therefore appear to flow away from that river. The Edwards flows out of it, although there is a break between the heads of the Billabong and the Murray. The Albury Billabong and the Edwards Billabong, as they are termed, appear to flow towards the Murrumbidgee and Edwards again in a north and north-west direction, or north slightly west. It is now thought a new thing to divert the waters of the Murray into the Billabong, but it is twenty-three years ago since the matter was first taken up by Messrs. Desailly, Lang, and others, who were connected with the matter at the time. The Tappal Creek, although it does not flow exactly out of the Murray, flows from the Murray westward or north-westward. Coming up again to the Billabong we see that it flows in the same way, and there are several watercourses between it and Albury, and between Tocumwall and Corowa. There is a series of dry creeks that appear to lead from the Murray instead of towards it. It is possible, therefore, and has been proved by actual levels, that by making a cutting into the Billabong the water could be distributed over the whole of that part of the country. Accurate surveys have been made of the country between Tocumwall, Moama, Deniliquin, Moulamein, and right down to Balranald, and it has been shown that the whole of the country from the Edwards to the river Murray could very easily be irrigated by gravitation from the Murray, taking the outlet of the Edwards as the source. Out of the Edwards River, a little below Deniliquin, near a station belonging to Sir Patrick Jennings, is the Wakool, which flows down parallel with the Murray and Edwards Rivers, taking up an intermediate position. All the watercourses between lead in the same, that is, a parallel direction, so that if a cutting were made in the river Murray through that large swamp above Moira and into the Edwards River, and the waters of the Murray raised so that they would flow into the Edwards, the whole of that country could be irrigated. Actual surveys were taken to determine whether that could be done, and it has been proved that it can be done. The fall would be about 7 or 8 inches to the mile in some places, and in others from 13 to 15 inches. I had very little to do with the Murray above Albury, the reason being that I did not think it would be judicious to interfere with the head waters of the river, or with any river the bed of which consists of gravel, because you would simply alter the equilibrium of the bed; and rivers the equilibrium of whose bed is altered are very difficult to restrain. You do not know what the result of your interference might be; probably the river might go in an opposite direction, and cause great devastation. It was on that account that I did not go up the Murray any great distance. I saw that gravel beds obtained in it, and besides there were other sources from which water could be obtained. The whole country between the Murray and the Murrumbidgee Rivers could be easily irrigated. Nature herself has shown us that the water flows from the Murray in the direction of the Murrumbidgee. She sets us an example by making the Edwards and Tappal Creek run from the Murray to the north and north-west. Coming to the head waters of the Murrumbidgee at Gundagai the gravel appears again, and it would be difficult to deal with the river in that locality unless you at once constructed a weir across it so as to secure the surrounding country from inundation. Coming down the Murrumbidgee you will notice that the contrary obtains—the waters flow to the southern bank. Take the Yanko Creek for instance. It appears to flow away from the river towards the Murray, showing that there is a fall in that direction. The fall may be slight, perhaps only a few feet, but still there is a fall. I have not been able to determine the exact grade per mile across there, but I have completed a considerable distance below the Yanko, namely, from Oxley across to Fire Braces. There is a fall in that direction, which would be south-west, quite opposite to the fall from the Murray. Now to deal with the Lachlan. That river appears to have formed a valley of its own. The waters flow in both directions, peculiarly in many cases. The Willandra Billabong appears to flow from the west to the east, but when it is flooded it runs apparently the other way. It is as nearly level as possible. I believe the country in that direction could be easily watered from the Lachlan, and there are many places where the water could be taken from the river in both directions. In going from Booligal across to Wilcannia about twenty-two years ago, I took a series of levels, but of course they are of little or no value, because I was unable to continue them owing to the want of water. The country there is practically level from Booligal towards Wilcannia, going across the head of the Willandra Billabong. Now with regard to the Bogan. From the Bogan at Dandaloo it is quite possible to deal with its head waters so as to send water down from Mudall towards Nymagee, between Nymagee and Cobar.

Fall from the Murrumbidgee towards the Murray.

The Lachlan.

Watering from the Lachlan.

Level country from Booligal to Wilcannia.

The Bogan.

1340. Have you any levels of that country? Yes; taking Mudall at 194·63, my datum was 200 from where I was.

Levels of the country.

1341. *Mr. M'Mordie.*] That is not with reference to any particular datum? No, it is simply my own. I could not connect with any railway surveys, because the distance is too great. The levels are comparative, just for instance as if you wanted to know the height of this place above George-street. My datum at that time was 200; the height was 194·63 at Mudall, and at Little Nymagee, which is about 7 miles from Nymagee, it was 96·37.

1342. *President.*] How far is it from Mudall to that point? It is calculated to be about 55 miles. Of course I did not chain the ground—I simply took levels in order to determine for my own satisfaction whether it was possible to get down that way. Some time or other it may be my good fortune to connect those levels, as I have done in other places. Sometimes nine or ten years have elapsed before I have been able to do that. The levels I have mentioned would allow plenty of fall for the water.

1343. *Mr. Barton.*] Where would you leave the Bogan? Just about Mudall.

1344. *President.*] Did you take any levels further on? No; I had no time.

1345. Does the country appear to fall in the same ratio? Yes; my levels show intermediate places that are very much higher. For instance, in running up I got up to 228, 224, and 222. I got considerably above that in many places.

Mr. J. Wright. C.E.

11 Sept., 1884.

1346. *Mr. Barton.*] Did you level the country in a straight direction, or did you look for the lowest country? There is a station called Panjee, or some such name as that, where there is a track leading to the river, and I followed that on to Nymagee.

1347. *Mr. Franklin.*] What is the highest reduced level you have? It is 229·77. There is a small creek that crosses the track I have spoken of. Its bank is 159·63. The distance can only be a few miles. Only 19 points were taken between the two places.

1348. *Mr. M'Mordie.*] Were you able to apply any checks to your levels? No, but I took them very carefully, and I keep my instrument always in adjustment. I rarely commit an error unless it is in making an entry in the book.

1349. But you had no opportunity of checking? No, not of checking the levels afterwards.

1350. Nor of closing a circuit? No; but in surveying from Moama, Tocumwal, Deniliquin, and Conargo right down the Billabong, and the Edwards to Balranald, and then closing again to an old bench-mark at Euston, in Victoria, I found I was only a foot out in 460 miles of levels. I took these levels with just as great accuracy.

1351. *President.*] Have you been above Mudall? Yes, I have been up the Bogan. I was driven up to an out-station belonging to a Mr. Armit only about four years ago, and from there to Tomingley Creek.

1352. Did you take levels there? No. From there I went across to Dubbo.

Cobar.

1353. Have you taken any levels between the Bogan and Cobar? No, but a friend of mine tells me that Cobar is lower than Nymagee, so that the water of the Bogan could be taken down to Cobar.

The Macquarie.

1354. Have you been on the Macquarie? Yes, and I have been on the Warren, but it was many years ago. I have been to the Marshes and on the Marthaguy Creek, at Sandy Camp.

Its fall.

1355. Have you taken levels there? No, but a friend of mine has. I have the details of the levels and can give you the fall of the river. It falls from Dubbo downwards about 2 feet 6 inches to the mile.

1356. It would appear that the country between the Bogan and the Macquarie is something similar to the country you have described between the Murrumbidgee and the Murray, so far as fall is concerned? Very much the same.

Country between Macquarie and Bogan.

1357. At or near Warren there appears to be a creek flowing from the Macquarie and joining the Bogan? Yes; I do not know the country from my own observation, but a gentleman connected with the Railway Department took a few levels across there at my request about three and a half years ago, and he tells me that the waters can all be led from the Macquarie towards the Bogan.

1358. *Mr. Barton.*] Did you ever see the Macquarie Marshes? Yes. I went down the Marthaguy Creek from Sandy Camp and then crossed over to the Marshes.

1359. *President.*] Have you any record of the height of the Macquarie just above the Marshes? No, I have not.

Levels.

1360. Nor of the Bogan? No; I took some levels at the Mara Creeks, but they have no bearing relative to one another. Levels were simply taken for the purpose of local supply. The fall varies from a few inches to 2 or 3 feet, so that without a uniform section it would be hard to determine what was its hydraulic slope on both those creeks. I have travelled over that country, and I feel quite sure that it could be watered from the Castlereagh, towards the Bogan.

1361. But you have no levels? No, I have none of that country. I have been from Coonamble right down to Walgett, but I took no levels. I have taken levels on the Namoi.

Levels on the Namoi.

1362. What levels have you taken there? From Walgett to Pilliga, and from Walgett to Wee Waa. The fall of the Namoi from Wee Waa to Walgett is about 11 inches per mile, that is, taking the distance as shown upon the maps. Of course I did not chain it. The distance is given on the maps as about 64½ miles.

1363. Have you any other levels higher up? No, I have no levels higher up, but they can easily be ascertained right up to Narrabri from Breeza, from the railway levels, which would give the actual fall. You could get the reduced level from Tamworth. That would give a good idea as to the level, because the water falls from Tamworth downwards.

1364. What is the comparative level at Wee Waa as compared with that of the Bogan? I cannot tell you that. It would take an immense amount of time and trouble to connect the surveys. What I have done has been simply for my own information.

Country on the Moomin, Dumaresq, and Gwydir

1365. Have you been on the other tributaries of the Darling further up? Yes, I have been on the Moomin, Dumaresq, and Gwydir. I have been all over that country for my own information, to Gunnedah right up to Marilla along Pooncarrie down the Big River, and along by the Moomin and Gwydir Rivers.

1366. What do you say then as to the levels of the country? The country is intersected by hills and undulations, and it appears to me that the whole of it could be watered if you could conserve the water in the watercourses. Taking the whole of the country from the Bogan right through it could be easily watered. The only difficulty occurs on the north-western side of the Darling. The water could be easily conserved between the Bogan and the Macintyre Rivers. There are so many watercourses and so much water flowing down there that a few thousand pounds expended on it would, I feel sure, secure ample supplies.

Conservation of water between the Bogan and the Macintyre.

The Darling.

1367. You have been along the Darling? Yes, the whole valley of the Darling.

1368. Have you any levels about the junction of the Macintyre with the Darling? No, I have not.

1369. You have been on the rivers leading from Queensland to the Darling? Yes, the Bokhara, the Narran, the Warrego, the Paroo, and the Culgoa.

1370. Have you any levels of those rivers? Yes, of a number of them.

Fall of tributaries to the Darling.

1371. Can you give us anything like the approximate fall? I could give you the levels in detail, but I have not brought them with me. The falls run from 8 to 14 inches in the mile. That would probably have to be reduced to from 6 to 10 inches; perhaps even less than 6 inches in many cases, because great lengths of the Culgoa, and of the Bokhara especially, are, comparatively speaking, level—the water flows both ways. In the lower trunk of the Bogan the water will flow from the Darling a long distance when its upper tributaries are flooded.

1372. *Mr. Barton.*] Down the Bogan? Yes, the water will be backed up. I have seen the Warrego backed up by floods in the Darling for 20 miles.

Out-run of the Paroo.

1373. *President.*] The fall in most of those northern rivers is about the same? About the same. The Paroo of course does not flow into the Darling, but runs into a sort of swamp or soakage, the same as obtains at Umberumberka Creek, near Silverton.

1374. You say the Warrego River loses itself? No, the Paroo.

Mr. J. Wright, C.E.

11 Sept., 1884.

1375. In sandy country? Yes; it is not altogether sand, nor is it clay; it is a a porous stratification.
1376. Do you think the water rises again, or is it lost altogether? If it goes anywhere it goes to the Darling underground; it goes away somewhere underground.
1377. It loses itself? Yes; the Narran does the same.
1378. *Mr. Barton.*] The Macquarie does pretty much the same? Yes, it runs into the Marshes. There is an interesting fact which came under my notice on the Namoi, at a place owned by Mr. T. P. Wills-Allen, near Gunnedah. That gentleman has a wool-washing station, where he washes a large number of sheep, and in doing so he uses 40,000 gallons of water per hour. With the idea of utilizing the water afterwards he thought he would irrigate a portion of his land, and he pumped for about a fortnight at the rate of 40,000 gallons an hour, but the water never extended beyond a certain point. On examination he discovered an immense crack in the alluvium, through which the water disappeared. He proposed taking me up there at the first opportunity to have the crack opened up in order to see what could be done to prevent the waste of water, and I expect to go up there in a short time to see him about the matter.

The Narran Creek in the alluvium on the Namoi.

1379. You say that the creeks which you have named, out to the west of the Darling, lose themselves in the same way that the Paroo does? Yes, they go into the earth, but they are found again about Silverton in what is called the soakage. The water simply sinks for a few feet, and then the magnesia in the clay formation renders it unfit for use. If you sink below the soakage you do not get the water.

The creeks about Silverton.

1380. Then you presume that the water found at Silverton is the soakage from the creeks that escapes underground? Yes, I am sure of it; there is no other means of its getting away.
1381. *Mr. Franklin.*] You say that on taking the levels from Mudall you found that for a distance of 4 or 5 miles there was a great depression? No, there was a rise of 41 feet, but that could be overcome easily enough. With regard to the water supply of the Darling, the Bogan, the Macquarie, the Castlereagh, the Namoi, the Moonbi, the Gwydir, and the Macintyre supply the Barwon, and the Barwon supplies the Darling and the rivers on either side. The rainfall from the Dividing Range on that side and the rainfall going southward from Queensland fill the Warrego, the Culgoa, the Bokhara, the Narran, and the Paroo. The whole of the country thereabouts is subject to inundations independently of the rivers altogether. In coming across from the Paroo some twelve years ago there was a heavy flood, and the whole of that part of the country was inundated.

Water supply of the Darling.

Inundations independent of the rivers.

1382. Has the amount of water discharged from the Macquarie River into the Macquarie Swamp been ascertained? No, it has not been ascertained.

Discharge of the Macquarie.

1383. I suppose it is assumed that the quantity is very large? Yes. Of course we can only arrive at an approximate quantity, because gauging requires years, and I do not think that there is any accuracy necessary in the gauging. We have the flood-levels, and we know that a certain fall will cause a certain velocity and a certain height. That has been determined by hundreds of observers, and if we know that, we can calculate the quantity of water that passes into the Marshes.
1384. *Mr. Barton.*] Unless it gets away underground? Yes.
1385. *Mr. Franklin.*] But is it not apparent that the ground is retentive in the Macquarie River up to the point of discharge into the Macquarie Swamp? Yes, it is retentive, but it is also retentive on the other side of the Darling. The Narran also is retentive; it is a large clay-pan apparently.

Nature of soil on the Macquarie and Narran.

1386. Then knowing that this portion of the Macquarie is impermeable if it were dammed at that point, and your levels showing that the fall is to the westward, would it not be possible to divert the water into the Bogan? Yes, quite easily.

Diversion from Macquarie to the Bogan.

1387. What would be the distance? I dare say it would be about 20 miles.
1388. *Mr. Barton.*] From the head to the Swamp? Yes; or you could go up to Mount Foster, and then divert the water to the heads of the tributaries of the Macquarie.
1389. That would increase the distance to about 30 miles, would it not? Yes.
1390. *Mr. Franklin.*] You have no levels between those two rivers to show if the fall is the same? No.
1391. Suppose we increase the flow of the water in the Bogan from the point mentioned, then by diverting the water from the Bogan for irrigation purposes we could compensate for the additional discharge? Yes, and I dare say it would probably do more than that. If it is ascertained that there is large waste of water we might go into the dry country.

Irrigation from the Bogan.

1392. And prevent any further flooding in the main river? Yes, you could utilize the water that now goes to waste without interfering with the rights of any frontages.
1393. *President.*] Do you think there is no spot between Dubbo and the Marshes where the water is likely to get away—no gravel beds? No doubt the Macquarie contains more gravel beds than any of the other rivers. If you dam or weir any river you must expect to lose a large quantity by soakage or percolation, and the more permeable the strata the greater is the quantity of water you lose. My object in taking levels has been a purely private one. I have had an idea that the construction of weirs on all the tributaries would mitigate if not altogether prevent the effects of protracted droughts, and I have arrived at the conclusion that it can be done.

Gravel beds in the Macquarie.

Weirs to mitigate effects of droughts.

1394. *Mr. Franklin.*] Are the tributaries of the Bogan very dry in ordinary weather? Yes. There are a few waterholes; in fact the whole of these rivers, when I saw them four months ago, were nothing but a chain of waterholes. The highest rise in the Namoi this year has been about 5 feet. That was at Gunnedah. It has been less lower down the river—about 2 feet 6 inches at Walgett.

Height of water in the Namoi.

1395. *President.*] And you consider the creek that goes out of the Macquarie near Warren is such a creek as the Yanko? Oh no. The Yanko in its cross-section is as large in some places as the Murrumbidgee. The Billabong in many of its cross-sections is larger than the Edwards.

Cross-section of the Yanko and Billabong.

1396. But I am speaking of the spot where it leaves the Murrumbidgee; are not the natural features very much like those of Duck Creek, where it comes out of the Macquarie at Warren and joins the Bogan? So far as surface appearance is concerned there is very little difference between the two.

Duck Creek.

1397. Each of them comes out of one river and runs across a belt of alluvial country into another? Yes; the Yanko of course joins the Billabong.
1398. But is not the country about the Macquarie and the Bogan very similar to the country between the Murrumbidgee and the Murray, down to the Yanko? Do you mean with regard to its profile?
1399. Yes, the surface? Yes, very much; it is a little more hollow. There are hills scattered about there which do not obtain in the other locality at all, but with that exception the general profile of the country is the same in both places.

Similarity of the country Macquarie-Bogan and Murray-Murrumbidgee.

1400. *Mr M'Mordie.*] I think you told us that the flood coming down the Darling and joining the river Murray does not raise the level of the Murray, but increases its velocity? Yes.

Mr. J. Wright, C.E. 11 Sept., 1884.

1401. While the cross-section of the river, the hydraulic mean depth and the fall remain the same, the velocity and discharge are increased? Yes.

1402. I think you said you would not take a canal out of a river where the bed was of gravel? Not where I knew that the gravel was movable, or unless I had assured myself that it would not be likely to alter the equilibrium of the bed.

Features of river-beds.

1403. What better bed would you like than a gravel bed? Rivers present three features of bed. The first is large stone and gravel intermixed; the next is sand, and the third is silt. The silt portion of the bed in all rivers has a slight fall; in sandy beds the fall is slightly increased, but with gravel beds the fall is the greatest that is known.

Objections to weirs in gravel beds.

1404. There is also the boulder bed and the rock bed; but I want to know what are your objections to cutting a river bank to take out the water when the bed is of gravel? I have no objection if you simply cut the bank, and by that means divert the water without obstructing the water-way.

1405. Would not a rock bed be better than gravel? Certainly.

1406. And gravel better than silt? No, because the gravel having a greater fall, the water moves faster. Take the case of the works in the Irrawaddy in India. The whole of the weirs were filled up in a very short time. Again, in the Arno, they filled up 72 feet in the gravel beds.

1407. So you would prefer to take the canal out of a sandy bed in preference to a gravel bed? Yes, unless the obstruction was not too great.

Offices held in India.

1408. You spoke of being on furlough from India in 1861: in what Branch of the Government Service were you employed? I was employed by Colonel Haigh, the Director-General of Public Works, at Peshawar.

1409. What was the official designation of your appointment? I was an engineer of the second grade at the time.

1410. Which of the grades—that of superintending engineer? I was superintending engineer of the roads at Peshawar; Colonel Haigh was the engineer in charge of the district.

1411. That is the next class to Chief Engineer? Yes.

1412. And you had charge of a circle? Yes, I had charge of a circle in the Roads.

1413. Do you know the head of the Bari Doab Canal? Yes.

Canals in India.

1414. Do you remember the nature of the bed? No, but I have all the particulars respecting it here. I have the condensed particulars, both financial and constructive, of the whole of the canals in India. I thought they might be of interest to some of the members of the Commission. The work is Darcy Jackson's; he was in charge of the Bari Doab canal at one time, I think.

Character of banks and beds of Billabong.

1415. *Mr. Gipps.*] What is the character of the banks and beds of the big Billabong Creek? The bed is in many places exactly the same as the surface of the surrounding country—red sandy loam, held together by streaks or bands of clay.

1416. It is perfectly impervious then? Yes; none of the dams that have been constructed on the Billabong appear to leak.

Discharge of Murray.

1417. Do you know the lowest discharge of the Murray at Albury? No, I do not. I do know, but I have not the data here.

1418. Do you know the discharge of the river at all at Albury or at Wentworth? I have not it with me.

1419. What evidence have you that the quantity of water in the Murray does not increase beyond the Darling River? The cross-section and the velocity were taken by the Engineer of the Water-works Department while I was Assistant Engineer in South Australia, and the quantity of water that flowed out of the mouth was afterwards calculated by Lieutenant Goalen, an Admiralty surveyor.

Increased velocity.

1420. Then how do you explain the increased velocity beyond the junction if the volume is not increased? That is explained by the fact that water rolls; it does not slide, and the pressure becomes greater. A greater weight of water is forced down at a greater rate, and forces what is before it at a greater rate.

1421. But that would not explain the increase of velocity, because there is apparently no increase of water with it? There is no apparent increase of volume, but there is an increase of velocity. Of course the faster water runs over a weir the greater the quantity that will flow over. If the velocity of approach to a weir is 2 miles an hour, and 1,000 gallons of water flow over the weir, if the velocity is increased to 8 miles an hour the quantity of water which passes over the weir will be greatly increased.

Sections of the Darling and the Murray.

1422. *Mr. Franklin.*] Do you know if there is in existence a section of the river Darling at its junction with the Murray at Wentworth? Yes, there are many.

1423. And also a section of the Murray at the same point? Yes, both above and below the Darling. There are numbers of them; I took no less than twenty or thirty myself.

Observations on the varying heights of the Murray.

1424. Do you know whether there are any observations in existence of the varying heights of the Murray below the junction, both at flood-time and otherwise, to strengthen your statement as to there being no rise in that part of the river? At a meeting of the Engineering Association I stated that the supposed increase of water from the tributaries did not raise the water in the recipient stream. Mr. Breadmore states, at page 235, vol. 27, Minutes and Proceedings, Institute of Civil Engineers:—

> From which it appeared that while feeders were discharging into the main river an additional volume of from 10,000 to 30,000 cubic feet per second, the main river appeared to be discharging the same total as before the junction of the tributaries.

1425. *President.*] I understand you to say that although a large body of water goes into the Murray from the Darling at Wentworth, the water in the Murray does not rise higher on its banks? No, but it is increased in velocity.

1426. *Mr. M'Mordie.*] And therefore in quantity? Yes, but there is no perceptible rise; there is an increase of velocity, but not of volume.

1427. *Mr. Gipps.*] Have you been at Wilcannia at all? Yes.

1428. Have you taken any cross-sections of the river there? Yes, two or three, above and below Wilcannia.

The river at Wilcannia and at Bourke.

1429. Is the river wider at Wilcannia than at Bourke? No, I do not think it is; if you take a long straight reach and a series of cross-sections and balance them, it will be found pretty much the same in both cases.

1430. What is the lowest level of the river at Wilcannia? That I could not tell.

1431. Does it ever run dry? That I could not tell; I have heard that it has been dry.

Mr. J. Wright, C.E.

11 Sept., 1884.

1432. *Mr. Franklin.*] You know the tallywalka? Which of them?—There are several.
1433. The one that runs parallel with the river about Wilcannia? Yes.
1434. Do you think it possible to put weirs on the tallywalka and to retain a large portion of the water? Yes, you could retain thousands of millions of gallons by the construction of weirs at those spots.
1435. Do you know the slope of the country from the tallywalka to the eastward? The slope is very slight; I think it is only an inch or 2 inches in the mile at most, so that sometimes it backs up and at other times it runs down; but there is such a number of these tallywalkas and millpools throughout the Darling country that weirs thrown across would not at all affect the water going down the Darling, while an enormous quantity of water could be conserved, because the beds of the dry creeks or anabranches of the Darling are apparently impervious.

Slope of country from tallywalka.

Conservation in tallywalkas.

1436. Do you think it possible to impound the water and divert it by shallow cuttings into natural depressions between the Lachlan and the Darling? Quite possible—I have determined that.
1437. And if on local examination we find such depressions, instrumental examination would lead to such work being done? Yes, it would. I will read the result of an actual survey.

Conservation in natural depressions.

The construction of two weirs on a watercourse upon the west bank of the Darling River, at a cost of £2,990 each, would impound 7,000 million gallons of water (sufficient to supply the city of Sydney for five years) cover at flood-level an area of about 14,000 acres, extend back from the river 18 miles, and give a water frontage of 61 miles; the weirs being respectively 17 and 20 feet in height, 104 and 93 feet in length, and 8½ miles apart.

That is from an article I wrote for a newspaper. I am now engaged in taking as nearly as I can the longitudinal sections of the river, with a view to seeing how much water could be conserved in the tributaries of the Darling. I do not see how the construction of weirs would affect, as some people say it would, the landholders lower down the river, because the first flood would fill the whole stream, and not only that, but the water would distribute itself—it would go away itself. If we had annual instead of periodical floods the loss sustained would not be half so great as it is: and the only way in which you can utilize small floods is by constructing weirs, thereby raising the water and distributing it artificially in the way that Nature does.

Utilization of small floods by weirs.

1438. Can you tell us in what direction you might naturally convey the water from the Darling? It would go in all directions. You require to see the country for yourselves in order to understand. You will find that the water will back up in the river and come out at a point (say) 10 miles below Wilcannia, and perhaps go 30 miles to the south and west.

Direction of distribution from the Darling.

1439. Would not that convey the idea that the bed of the Darling is in some cases not very much higher than the country laterally; that is when you take a series of levels at right angles to the course of the river? No, only slightly so; it rises towards the Lachlan. I am of opinion, and I hope to live to prove it, that there is a possibility of taking the water from above Wilcannia or higher up to Oxley.

Rise toward the Lachlan.

1440. Do not you think it would be worth while to make an examination in order to ascertain whether if the water were impounded in the tallywalka we could find a natural fall towards Oxley? That is what I would like to do, but I cannot afford it. I hope to be able to do it. I shall connect some levels in a week or two that will resolve a portion of the doubt.

Diversion from Darling to Oxley.

1441. Are you aware of any dry lakes in that neighbourhood at all? No; there is apparently about Conoble what appears to be a large indentation, but whether it would be a lake or not I cannot say. I went across from Ivanhoe to Coonamble, and there you leave the sand-hills between the Darling and the Old North Road, as it is called. To all appearance it is very level country.

Indentation about Conoble.

1442. *Mr. Gipps.*] Does the bed of the river Murray ever rise above the surrounding country? Nowhere that I am aware of.

Height of bed of the Murray.

1443. Nor of the Murrumbidgee? Nor of the Murrumbidgee.

Of Murrumbidgee.

1444. Nor of the Lachlan? Well, perhaps the Lachlan would, down about Balranald, though I scarcely think it would.

Of Lachlan.

1445. It does between Forbes and Condobolin? I have not been there much to take notice.
1446. *President.*] You have made some experiments in regard to evaporation, have you not? Yes.

Evaporation.

1447. Will you give us any information you have? The information I have I supplied in full detail to the Government Astronomer, Mr. Russell; but the object of my observations was to determine the maximum evaporation.
1448. *Mr. Barton.*] In certain districts? As near Central Australia as possible—the driest portions. My assistant has been three years and myself twelve months taking observations accurately every day, and we find that it varies from 90 to 98 inches per annum; that is the maximum evaporation.

Maximum evaporation.

1449. *President.*] That is on the water surface? Yes; Mr. Russell has all the details; I have no doubt he would willingly supply the Commission with them, and save me the trouble of again writing them out. The observations were obtained in this way:—On a sand ridge at about 80 miles from Barringun, near the border of Queensland, I had an iron tank 10 ft. 6 in. by 10 ft. 6 in. by 1 foot. Inside of that I put a lining of 3-inch Oregon pine, with 3 inches of earth under the lining on the bottom. Every day the tank was filled with water and the evaporation recorded.
1450. *Mr. Barton.*] Was the tank in an exposed situation? Yes, on a sand ridge on an open plain.
1451. *President.*] Those observations, you said, have extended over three years? Yes, this is the fourth year.
1452. *Mr. Gipps.*] What was the actual depth of the water? Six inches—that was the maximum depth. It went down to 2 inches sometimes before we filled it again. In conserving water for pastoralists it is necessary to know the maximum evaporation—not the minimum or mean evaporation.
1453. *President.*] Would the evaporation be the same if the water was deeper? No, it would be very much less.
1454. Have you made experiments to ascertain how much less? I have had several opportunities of doing so. At Nelshaby, on the Flinders Range, while assistant engineer in South Australia at the Napperby dam, the greatest evaporation was half an inch in one day. That was in 1876 or 1877, but the mean annual evaporation was about 4 feet 5 inches.

Greatest evaporation in one day.

1455. What depth was the dam? From 12 to 14 feet.
1456. And the evaporation was about 4 ft. 5 inches in twelve months? Yes. In a tank at Buerta near the Queensland border the evaporation amounted to 7 feet, but no doubt a certain proportion of the water was lost by percolation and soakage. The Astronomer of South Australia, Mr. Charles Todd, gives the mean annual evaporation in that Colony at 6 feet. In India the evaporation is given at a quarter of an inch per day.

Evaporation in South Australia: in India.

1457. *Mr. M'Mordie.*] In what part of India? The Red Hills, I think, near Madras. 1458.

Mr. J. Wright, C.E.

11 Sept., 1884.

1458. *Mr. Gipps.*] At Bombay, at the reservoirs there, the evaporation is given at 80 inches for the whole year? I think the instructions given to the hydraulic engineers in charge are to have their calculations on a quarter of an inch per day.

Mean evaporation.

1459. *President.*] From the experiments you have made, what do you consider to be the mean evaporation? About 5 feet.

1460. What would be the evaporation in a tank 20 feet deep? 5 feet, but that is mere assumption. I have no definite data to guide me, except indirectly.

1461. But you state that the actual evaporation from a tank 12 feet deep was 4 feet 5 inches? Yes.

1462. Well, if the tank were 20 feet deep the evaporation would not be so great in proportion? Well, the difference between the two would not be so great. The heat of the sun is supposed to extend to about 12 feet, but I do not think it can affect the water to a depth of 20 feet. I found that in the driest part of the country the evaporation from an open exposed tank was about 5 feet.

Tanks.

1463. Have you had any experience with reference to tanks generally? I have constructed tanks to hold altogether some four or five million gallons of water.

Best depth for tanks.

1464. What depth do you consider a serviceable tank would be? The greater the depth the less the evaporation; and the smaller the area you expose to the sun, the less the evaporation also. For pastoral purposes—that is for watering sheep and cattle—I think from 20 to 30 feet is the best depth if you can get it. Of course, you are limited in many places by the stratification, and again by the extra cost of cutting to that depth. For the purpose of water conservation the best depth is from 20 to 30 feet; for economy, the best depth is about 12 feet.

1465. *Mr. Barton.*] From 12 to 20 feet? Yes; the cost rapidly increases when you go further than 12 feet.

1466. *President.*] What depth of water do you consider would contain permanent water without fail—what depth of tank would be required to contain sufficient water for one or two years' drought? That would depend entirely on the consumption. About 20 feet would be an ample depth, assuming that none was used. We have tanks that were excavated some five years ago in country that has not yet been stocked, and there was plenty of water in them four months ago.

1467. *Mr. Franklin.*] But in two years the water would be reduced by 10 feet? I do not know what the evaporation was. Four or five tanks were sunk and they happened to get filled by one of the tropical showers, and there was plenty of water in them in February last.

1468. *Mr. Barton.*] Where are those tanks? West of Mount Urangaret, between there and Strangway Springs, west of the overland telegraph line.

Batter of tanks.

1469. *President.*] What batter should a tank have? I give them as little as possible. I prefer 1 to 1, and to secure the tanks so that sheep and cattle cannot get into them; but 1½ to 1 is ample.

1470. Do not you think that with 1½ to 1 there is a danger of the sides falling in as the water recedes? No, I have never found it to be so. If disturbed by the sheep, the banks will no doubt undermine and fall in.

Natural indentations.

1471. If water was conveyed from the various rivers through dry country in the manner you have described, and tanks were made in the vicinity of the stream of water, do you not consider that it would be a good plan to fill the tanks from the stream as it was necessary? Yes; but I do not think that it would be necessary, because there are sufficient natural indentations which could be availed of if you could only get the water to them.

1472. Without making tanks? Without making tanks.

Damming of dry creeks.

1473. But would not the same quantity of water last longer in a tank than in an open swamp? No doubt; but there is a number of dry creeks intersecting the whole of Australia, from 10 to 20 feet deep, in which there is no water except during flood-time. They could be dammed and filled with the flood-waters.

1474. What I mean is that, supposing a scheme to be adopted for diverting the water from the various channels through the country by means of weirs and dams, would it not be wise so to make the dams that water could be run into them from the streams after two or three dry seasons? It would make assurance doubly sure—it would ensure a supply of water whether you had floods or not.

Depressions in tributaries of rivers serving as tanks.

1475. *Mr. Franklin.*] Do you not think that in the tributaries of the rivers we have been discussing it would be possible to find such depressions as you speak of, and to further deepen them by an inexpensive mode of excavation, so that by damming one end we could provide such tanks as you have been asked about? Yes; that was what I was about to explain.

1476. Then by the establishment of small weirs we could divert the first rush of mountain torrent and fill these depressions, although formerly they were not connected with any tributaries? Yes.

Tank at Buerta.

1477. *Mr Gipps.*] Or perhaps by forming embankments around them? Yes, there are numbers of ways in which it could be done. For instance, we have one at Buerta. You may see a section of the dam attached to the Report of the Select Committee on the Pastoral Dams Bill. By means of a dam 11 feet high we throw the water back 56 miles. It inundates the country the same as if the heaviest flood ever known had occurred. That is between Strzelecki's and Cooper's Creeks, in one of the dry watercourses there.

Depressions at heads of rivers.

1478. *Mr. Franklin.*] Do you think there are any very large natural depressions at the heads of the rivers, where, by making weirs, we could store an enormous quantity of water and regulate its discharge? Yes, I could point out a number of places.

1479. You are aware that portions of the country are often flooded by rain-storms, and that the water never finds its way into the rivers at all? Yes; it cannot disappear by evaporation—it must disappear by soakage. I have travelled 120 miles in from 6 to 18 inches of water.

Storage of water from rain-storms.

Improvement of navigation on the Darling.

1480. Do you think that if we diverted those great rain-storms into natural reservoirs, we could prevent that constant rush of water that inundates the flat country? Yes, and let it out at will. You could control it as it is done in some of the rivers in France. It would really improve the navigation of the Darling if you dammed the whole of its tributaries, because the navigation might then be made constant, instead of intermittent.

Conservation in the Namoi.

1481. Which would be the best part of the river heads to deal with, or the most favourable part of the country for such work? If you want a general idea of it, I think the Namoi would be as good a river as any other. It is not the largest river and it is not the smallest, but it is about the mean, and its discharge is also about the mean. You might take either the Macquarie or the Gwydir or the Namoi or the Bogan. As a mean I think the Namoi would be about the best. See what an amount of water could be conserved

on the Namoi by means of weirs, the uses to which it could be put, the amount that could be diverted, and the distance to which it could be diverted. Mr. J. Wright, C.E.

1482. *President.*] Are there any large natural basins about the head of the Namoi? Yes, at Gorah there is a lake which would give a frontage of 50 or 60 miles of water. Then there is what is called the Gunnible Swamp, which would hold 5 or 6 feet of water. It has not been filled for a number of years. Down at Wee Waa there are several lakes or indentations, as they may be called, which could be filled with water, their lower portions being dammed up. I could mention hundreds of places where there are indentations of that kind. 11 Sept., 1884. Natural basins at head of Namoi.

1483. *Mr. Franklin.*] Do you think that if we sought for information from the pastoral tenants they would inform us of such places, or would they, for purposes of their own, withhold the knowledge? I have always found them very willing to supply me with any information they possessed, although certainly they have not felt inclined to accept professional advice to the extent which perhaps a professional man would like. It should be borne in mind, however, that the information they would give, though not intended to mislead, might do so. Information from pastoral tenants.

1484. Did you find in many cases a feeling on the part of the pastoral tenants that the filling up of the indentations would be a loss to them? No, I think they know the value of the edges of the water—they would be only too glad to see the water there; although it would curtail their grass, the gain would be greater than the loss.

1485. *President.*] But if you made a reservoir with 60 miles of frontage, that would take up a whole station? No, it would not when you go all round. When I mentioned the Gorah Lake, that was an exceptional case. Gorah Lake.

1486. *Mr. Franklin.*] Do you think that, in the interests of water supply on some stations, the holders of the property would be induced to bear the expense of testing the levels between their places and the river? No; their insecurity of tenure causes them to keep their pockets closed as tightly as possible. If you gave them a fixed tenure so that they would be assured in possession of the land for a number of years they would do so, but at present, when the making of improvements simply brings blackmailers upon them, they do not care to spend a single shilling more than they can help. If they had a secure tenure I do not think there would be any necessity for the Government to take in hand any scheme of water conservation, for pastoral lands at any rate. Testing the levels at the expense of property holders.

1487. *Mr. Gipps.*] With regard to your objection to weirs on gravel beds, I suppose it would not apply if the banks of the river could be made intact? No.

1488. Therefore a movable weir which would do that would be unobjectionable? Yes. Movable weir.

1489. *President.*] You said, I think, that you did not go above Albury to see whether anything could be done to divert the water of the Murray, on account of the gravel in the river-bed? Yes, I only went a short distance above Albury. The deposit is black soil, very friable. Nature of the Murray banks above Albury.

1490. But the banks of the Murray higher up are not composed of black soil as a rule? Well, it seemed to me to be good agricultural land on the sides of the river—nice black soil, and friable.

1491. As you go up the Murray to the point where the water can be diverted to the Billabong, wherever there is any silt or any obstruction in the river, there you find large water-worn boulders? And gravel lying between them.

1492. Yes, but not much gravel, and there are no flats in the river at all—in many places the river runs through a gorge: where that is the case the river-bed would not be interfered with by diverting the water? No, not if the banks are good and sound and the river runs through a gorge or among rocks—that is the best situation for diverting water.

1493. And if a weir were placed there, the fact of taking away a portion of the river water would not be likely to affect the channel below? No, it would not affect it in the least. Effects of weirs on river-beds.

1494. I thought you meant that the channel would be affected below the weir? No, it is above the weir where the bed of the river would be affected. The water would carry the gravel down and materially increase the slope. It might break away and place itself beyond your control then.

1495. But supposing that the country of the Upper Murray is not as you suggested, no harm would arise from diverting a portion of the water into the Billabong? Not a portion of the water, but the proposition has been to divert the whole of the waters—to let them flow out and in again. But when you divert a portion of the water, it simply means the raising of it by a series of small weirs to the height you want it, and then diverting it, without affecting the equilibrium of the bed at all. Diversions from the Upper Murray.

THURSDAY, 2 OCTOBER, 1884.

Present:—

Mr. BARTON, M.P.,	Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E.,	Mr. MURRAY, M.P.,
Mr. GIPPS, C.E.,	Mr. M'MORDIE, B.E.,

W. J. LYNE, Esq., M.P., PRESIDENT, IN THE CHAIR.

Arthur Pepys Wood, Esq., called in and examined:—

1496. *President.*] What position do you hold, Mr. Wood? That of Assistant Engineer in the Roads and Bridges Department. A. P. Wood, Esq. 2 Oct., 1884.

1497. What experience have you had in reference to the tanks and wells on the stock routes of the Colony? I have been connected with those works for about fifteen years.

1498. Have you recommended most of the tanks and wells which have been put upon the stock routes in the western part of the country? Yes.

1499. And you know that part of the country well? I am pretty well acquainted with it.

1500. Have you read before the Royal Society any papers in reference to it? A paper of mine was read before that Society. Paper read before Royal Society.

1501. I suppose you have none of those papers with you now? Yes, I have a copy, which I produce. (*Appendix I.*)

1502. In this paper you deal principally with water supply for stock routes and water supply for irrigation? Yes.

1503.

A. P. Wood, Esq. 2 Oct., 1884.

1503. In the western country what machinery do you generally use for putting down wells—boring wells for water? Of late years that work has been carried out by a different Department, but when I went to that district first we put down a good many bores and then used the old-fashioned rods.

1504. Then your particular duty has been in *sinking* for water and not *boring* for water? Yes, of late years.

Size of tanks. 1505. What is the particular size of tanks you generally provide? From 18,000 to 20,000 cubic yards, and not less than 18 feet deep.

Disposal of spoil. 1506. Do you always make silt tanks? Invariably. We also dispose the excavated material in an embankment surrounding the main excavation, within which, when the features of the country admit of it, the water is stored above the natural surface.

Storage above natural surface. 1507. In what way do you store it above the natural surface? When possible, by gravitation.

1508. In every case? No, there are many places where the features of the locality will not admit of it; in such cases we purpose erecting pumping machinery.

Depth of wells. 1509. What is the depth of the wells on the other side of the Darling River? They vary very considerably, ranging from 50 to over 500 feet.

Quality of water. 1510. Is the water good? It varies in different localities. I think that as a rule it is better on the north side than on the south side of the river.

Nature of drift and soil. 1511. Is the nature of the drift and soil you passed through there the same on the north as that on the south side of the river? No, it is different. On the north side our wells have been sunk through alluvial deposits, through clay and sand-beds, while on the south we have had to deal with rock in many cases.

1512. When you refer to the north side you mean the north-west? Yes, the north-west side of the river.

1513. Is the difference particularly marked at the Darling by the division of the country by that river? I cannot answer that question, as we have not put down any bores or shafts between the Darling and the Manahra range.

Distance from the Darling. 1514. How far is that from the Darling? About 70 miles from Wilcannia, and it is here that when travelling northwards a great change is to be noticed in the character of the country.

Character of country between Manahra range and Darling. 1515. Between the Manahra range and the Darling the country would be similar to that on the south-east of the Darling? No, I believe the character of the country alters here; that to the south of the range consisting of immense alluvial deposits, while to the north of the range, between it and the Darling, the alluvial is shallower and rock soon met with; the country between this range and the river appears to me to be very similar to that on the north or north-west of the river.

1516. Then the Manahra range is to the south-east of the Darling? Yes.

1517. Opposite what part of the Darling in the Mount Manahra range? It is about south-east from Wilcannia.

Dividing range between Lachlan and Darling. 1518. You consider that range is a continuation of a range of country that comes east from Cobar? It appears to be a portion of the dividing range between the Lachlan and the Darling.

1519. Do you know of any levels that have been taken there? I have never taken any levels in that district that could be referred to a general datum, but I believe the Railway Department have done so.

Class of country north of Darling and west of Paroo. 1520. Does the same class of country extend across the Darling? North of the Darling and west of the Paroo there are many low ranges, and the sinking there, as I have already stated, is in many cases through rock, the alluvial deposits being much shallower then they are on the great plains. Between the Paroo and the Warrego I do not know the country.

1521. Is that the same line of country you have just been speaking about as to the south-east of the Darling? I am not a geologist, and therefore cannot give a positive opinion, but there appears to me to be a marked difference between the alluvial plains south of the Manahra range and the country to the north-west of the Darling.

Occurrence of older schistose rocks. 1522. I understand you to state that in sinking wells to the north and north-west of that division they go through what geologists term the cretaceous formation? I am informed that they do in many localities, but not all over that section of country. Schistose rocks of an age long antecedent to that formation occur in many places.

1523. And to the south? Through alluvial deposits.

1524. Have you any experience of the country between the Paroo and the Warrego? None.

Country east of the Warrego. 1525. Have you any experience of the country to the east of the Warrego? Yes.

1526. Is the formation there similar to that of the country west of the Paroo? I cannot give a geological opinion, but consider that portions of those districts are similar.

1527. Have you had any experience in sinking wells there? No; I have only constructed tanks in that district.

1528. Have you been further east towards the Barwon? Yes; but no wells or bores have been put down by us in that locality. There are natural springs in the Warrego district.

Natural springs in Warrego district. 1529. In what portion of the country? Between the Darling and Warrego there are several flowing, and numerous mounds indicating the sites of springs now extinct.

Their origin. 1530. What is your opinion in reference to these springs—do you suppose the water to come from some distance? I believe these springs are of comparatively local origin—that the pressure is obtained from the higher lands in the district feeding the drift-beds.

1531. Then you are of opinion that they are to some extent local? I am inclined to think so.

1532. You do not suppose that these springs are caused by the fall of water in Queensland? It is possible, but I am inclined to think they are of more local origin.

Storage of water. 1533. When you get south-east to the Barwon, Gwydir, and Macintyre, is the nature of the country such as to allow of the storage of water by means of artificial dams? You are then in level country, where the features are unfavourable for the storage of large bodies of water having any considerable depth.

1534. Which heads of the Darling do you consider most suitable for such a purpose? I have never been in Queensland, so I can give no opinion as to the feeders in that Colony, but the branches heading up in our coast range could be largely utilized.

1535. You have been to the east of the Darling? Yes; I have been on the Bogan, Castlereagh, Macquarie, and portions of the Namoi.

1536. Have you been on the Gwydir? No.

Nature of country on the Namoi. 1537. What is the nature of the country on the Namoi? The greater part of the country traversed by the Namoi is unfavourable for conserving large bodies of water, and the fall of the country is so slight that water conserved in the drainage channels could only be utilized by pumping. On the upper reaches of this river the conditions become more favourable.

A. P. Wood, Esq. 2 Oct., 1884.

1538. What I wanted to find out was whether there are any spots where the ranges come together near the river, with comparatively level country above, where lakes of water could be stored or conserved? I do not remember any such places.

1539. Could it be done in reference to the Macquarie or the Castlereagh? Both these rivers, and more particularly the Macquarie, are more favourably conditioned than the Namoi. Macquarie more favourable for storage than Namoi.

1540. And the Bogan? The Bogan, where I know it, is not so well circumstanced for that purpose as is the Macquarie. There are many places where shallow water could be conserved, but depth would be difficult to obtain.

1541. You have been down to the Macquarie Marshes? No. Mr. Dalglish, the late District Surveyor at Dubbo, is well acquainted with that district, and could give you much valuable information on this question.

1542. Do you know any of the country from the Macquarie to the Bogan? Yes; between the Bogan and the Macquarie and the latter river and the Castlereagh the country is on their lower reaches nearly a dead level. Country between Bogan and Castlereagh.

1543. Does that dead level extend as far as the Namoi? I think not.

1544. Do you think, from your knowledge of the country, that it is so level that the whole of these rivers forming the head waters of the Darling could be connected by canal? There are places where some of the rivers could be connected; in fact there are natural connections when the rivers are in flood. Natural connection between Castlereagh, Macquarie, and Bogan.

1545. From the Castlereagh to the Macquarie and Bogan? Yes.

1546. You have lately been at Silverton? Yes.

1547. That is rangy country such as you have before described? Yes. Rangy country at Silverton.

1548. Were you there when they found water by shallow sinking? Yes.

1549. Is it drainage from lands in the neighbourhood? It is merely local.

1550. The sinking is not deep? No; about 40 or 50 feet is the shallowest, and 150 or 160 the deepest, in the neighbourhood of Silverton.

1551. In the case of any wells you have had to do with have you found a flow of water, or what was supposed to be a flow of water? No; but I heard of a case of the kind near Hillston, where a man sank a well to a depth of about 105 feet, when he struck water in an open drift which he stated had a regular flow agreeing with the fall of the country. Flow of water in wells.

1552. Who was it said so? The man was a selector residing about 2 miles from Hillston; he is well known there, but I forget his name.

1553. How far is the Willandra Billabong from Hillston? About 22 miles. Willandra Billabong.

1554. Is that a dry billabong, or generally dry? It is generally dry, its only source of supply being from the Lachlan when in flood.

1555. It flows to the Lachlan in dry periods, and from it when there is a flood in the river? I do not think that is the case, though, under certain conditions, the water for some distance would run back into the Lachlan as that river fell. Messrs. Haines & Whittingham improved the outlet from the Lachlan into the billabong, the channel where it left the river being very ill defined. The cutting made would, unless sluices were provided, allow of a greater reflux when the Lachlan fell, though at the same time there is an actual fall from the river in both the artificial and natural channels. The quantity draining back would be dependent on the excess of the water-level over that of the bottom-level of the off-take. Direction of its current.

1556. Only to that extent? That is all.

1557. Have you had any experience of the country on the Murrumbidgee and the Murray? A good deal more on the former than on the latter river. I was in that district during the great flood of 1870 or 1871, and saw the way in which the waters of the Murrumbidgee, Lachlan, and Darling spread out over the country. The Lachlan waters extended out to within about 20 miles of the Manahra range. Flood of 1870 or 1871.

1558. As a matter of fact, the whole country between the Lachlan and Darling was covered with water? There could not have been more than about 30 or 40 miles between them, but the whole country was not under water, as the flood was confined to certain courses by the natural features of the country.

1559. Then the water reaches between the Lachlan and the Darling, and fills up the country right across from the Lachlan to the Darling? I did not say right across, about 30 or 40 miles of high land must have divided them. The country between the Lachlan and the Willandra and thence north-easterly is so level that the water could be taken in almost any direction. Level country between Lachlan and Willandra.

1560. *Mr. Franklin.*] You refer to the Willandra Creek, which is about one-third of the distance between the Lachlan and the Darling? Yes, the Willandra creek floods; they are Lachlan River water.

1561. Do you think it would be an advantage to lock the off-take of the Willandra Creek with weirs and under-sluices to retain the flood-water? I think regulating works would be an advantage, also a weir in the Lachlan to throw the water into the Willandra at half-flood; but to take full advantage of the river when high enough to flow into this billabong the *régime* of the channel should be improved, to allow of the water being carried well forward. Locking the off-take of the Willandra.

1562. Then you think that an instrumental examination would be of benefit there? Most decidedly, in all cases when a little assistance to Nature will achieve great results.

1563. The country being so level, if you get a great head at flood-times you could keep a good quantity in store? Yes, but it must not be forgotten that the storage would be rather shallow. Storage at flood-times.

1564. Do you know any special features on the upper part of the Macintyre or Macquarie where an instrumental examination would be beneficial with a view to form a large storage of water? Yes, but my recollection will not allow of my naming any particular spots; but no one travelling up these rivers could fail to notice the favourable features that exist for carrying out such works. Spots for storage on the Upper Macintyre and Macquarie.

1565. *President.*] What distance do you suppose the water could be diverted across that flat country from the Lachlan through the Willandra Billabong westwards? About 150 miles; I have seen the waters running into Barney's Swamp, and the waters have been known to run out much further. Distance the water will reach by the Willandra.

1566. Do you know anything of the lower portion of the Darling below Menindie? I have travelled along that section of the river, but cannot give any information that will be of service to you.

1567. You cannot give us any information as to the possibility of storing or diverting the water into the large anabranch? I do not know enough of the locality to care about giving a decided opinion, but from what I remember of the place I think that it could easily be done if proper headworks were constructed at the off-take from the Darling. Storing or diverting water into anabranches of Darling.

1568. From Menindie towards Bourke are there many places where the waters of the Darling could be diverted into the anabranches and be carried any distance from the river? I have no personal knowledge of

A. P. Wood, Esq. 2 Oct., 1884.

of any cases where the Darling waters could be diverted into these natural channels and carried any great distance back from the rivers, but there are many cases where water could be turned into these channels and into shallow so-called lakes fed by them.

Depth of permanent tanks. 1569. In tank excavation what depth do you think a permanent tank should be made? Not less than 18 feet.

Batter of tank. 1570. And what batter do you give? We vary it according to the nature of the soil, but we now give a flatter batter than in our earlier works; then they were as steep as 1 to 1, and now in some cases we make them 2½ to 1.

Evaporation from tanks. 1571. Have you any knowledge of the evaporation that takes place in tanks made by Government? We have never measured it, and it would be a difficult thing to allow for loss due to evaporation and that due to percolation. The evaporation too must always be variable in different works, being greatly dependent on the surrounding conditions in each case, and these are seldom the same. Generally speaking, in a tank containing 18 feet of water I do not think the evaporation would exceed 4 or 5 feet.

1572. What would it be in shallower tanks? That is dependent on many conditions, and largely so on the depth. Very shallow water will evaporate at a more rapid rate than deeper water. The nature of the soil too, has, in my opinion, an influence on the temperature and evaporation.

1573. You have no knowledge of the Paroo? No

1574. Nor of the northern rivers running into the Darling? No.

Information by Commission visiting various districts. 1575. *Mr. Franklin.*] Do you think that as a Commission we could gain much information by visiting the various districts, from the pastoral residents, as to the improvements they have made on the runs—would they volunteer information? I believe they would be glad to give it and assist you in every way.

Irrigation work at Grungle station. 1576. Do you know any particular runs about Hay where they have made advances in the storage of water and in irrigation? I do not know where they have made any advances in storage, but at Grungle, a station belonging to Mr. Learmouth, irrigation work has been carried out, and Mr. Mair, the General Manager, kindly gave me his experience in a letter which I have embodied in the paper I handed in as evidence.

Trial shafts to test level of water. 1577. Do you think it possible to make arrangements with the pastoral tenants to sink trial shafts to test the level of the water? I never tried them; I question whether they would like being troubled in that way. I also question whether you will find the work necessary, as the lessees have so many shafts sunk that in all probability you will be able to obtain the information you require from existing works.

Best method of conserving water by weirs or dams. 1578. *Mr. M'Mordie.*] Can you suggest the best method of conserving water in these rivers by weirs or dams, or its diversion into anabranches or lakes? Where the natural conditions are favourable they should be taken advantage of; but it must be remembered that in conserving waters in anabranches and lakes you are as a general rule conserving it in country where the fall is so small that you will be unable to distribute the water without pumping appliances. I therefore think that though from some points of view great advantages will be gained by such conservation, still for the purposes of irrigation the water should be impounded where there is sufficient fall in the country to allow of its being drawn off and distributed by gravitation. In such localities too the natural features are more favourable for economical artificial storage. There are many places on the upper reaches of our rivers where weirs could be cheaply and safely constructed that would impound very large bodies of water.

1579. You are not afraid of silt in this weir? On the lower courses of our rivers it might be a difficulty, but not to near the same extent on the upper reaches, where, from the nature of the country through which the rivers flow, a smaller quantity of silt is brought down, and where the facilities for scouring are greater.

1580. Do you recommend permanent or movable weirs? That depends on special conditions.

The Commission should direct their attention to the whole Colony. 1581. Do you know to what places the Commission could profitably direct their attention, having regard to the objects they have in view? The question is of so broad and national a character that I am of opinion that the Commission should direct their attention to the whole Colony, more particularly to the western falls, and then examine the nature of all our river systems and of the country the water is to be diverted on to.

1582. You have no knowledge of the Darling? Not of the upper and north-eastern tributaries.

Character of wells north of the Darling. 1583. *Mr. Gipps.*] What is the character of the wells north of the Darling, as regards their artesian properties or otherwise—is it of a soakage or artesian quality? They are not artesian.

1584. What is the average depth of them? Speaking roughly, I would say about 150 or 160 feet.

1585. What do you consider would be about the height of the surface there above the sea-level? Wilcannia is I believe about 300 feet above sea-level; running out north-west the country excepting the ranges would be about the same elevation, that is, on a course transverse to the axis of the river.

Positive and negative artesian supply. 1586. What do you understand by artesian water? Positive artesian is where the water when tapped rises above the surface, and a negative artesian supply is where the water when tapped rises above its confined level, but not above the surface.

1587. Have you travelled on the Murrumbidgee? Yes.

1588. On the Upper Murrumbidgee? Yes.

Character of bed of the Murrumbidgee. 1589. What is the character of the bed of the river? On the upper reaches the river flows in a well-defined valley, the ranges being generally rocky, and in some places closing in and confining the flow to a rocky gorge, in other places opening out with broad flats through which the river runs.

1590. Is the Murrumbidgee a permanent river? Yes, I have never seen it stop running.

Murrumbidgee fed by snow and springs. 1591. *Mr. Franklin.*] It is snow-fed? Yes, and it is also fed by many springs.

1592. *Mr. Gipps.*] Have you any idea of the quantity of water supplied to the Murrumbidgee near Cooma? No, nor am I aware that the flow was ever gauged.

1593. Does it flow in a good stream at that distance from the head? Yes.

Chief supplying tributaries. 1594. Where does it receive its chief supply after leaving the mountains? From the Bredbo, Umaralla, Queanbeyan, Molonglo, Goodradigbee, and Tumut Rivers.

1595. Do you know anything about the tributary rivers on the eastern bank—are they permanent or otherwise? Permanent as far as my knowledge goes.

1596. Do they bring down any silt in flood-time, or are they clear? Some of them send down silt in flood-time.

1597. Have you seen the Goodradigbee and Tumut Rivers in flood? No; I have seen them in freshes.

Places for weirs on tributaries of the Murrumbidgee. 1598. *Mr. Franklin.*] Do you know any point on the Tumut River before its junction with the Murrumbidgee where a dam might be put? No; my knowledge of the rivers is general, and without being able to indicate the exact place I know that sites exist where weirs could be constructed.

A. P. Wood, Esq.
2 Oct., 1884.

1599. You do not know that the bed slope of the Tumut is much greater than that of the Murrumbidgee? No, I do not; it must depend upon what section of the Murrumbidgee it is compared with. As you get into the mountains the fall of course increases.

Supply of country between Junee and Cootamundra.

1600. I take the great rise from Gundagai to the Tumut and the fall of the river into the Murrumbidgee; are there any points on the Murrumbidgee where the water could be dammed and conveyed across from the Murrumbidgee into the flat country between Junee and Cootamundra? That is a question of level, but the rise must be very great above Junee.

Nature of bed of the Murrumbidgee

1601. *Mr. Gipps.*] Where does the rocky bed of the Murrumbidgee terminate? Where the river enters on the alluvial plains, above that rock is frequently met with, alternating however with an alluvial channel.

1602. What is the average fall of the Murrumbidgee do you think, up to Yass? I have never levelled it, and cannot possibly say.

1603. You do not know the quantity of water the Murrumbidgee discharges at Yass? No, nor am I aware that the river has been gauged there.

Diversion of Murrumbidgee into Lake George.

1604. Do you think it advisable to divert the Murrumbidgee at Cooma into Lake George? That is a question that ought not to be recklessly answered. It would require a very accurate knowledge of the country and of the levels to be able to give an opinion on that point.

1605. Would it be advisable, if it could be done, to do it, for irrigation purposes? It would depend to a great extent on whether the water could be economically brought there and then economically distributed.

1606. Are there any positions you could recommend on the Murrumbidgee for lakes? No.

Darling River:

1607. Have you travelled up the Darling River? Yes.

1608. From what point? From Wentworth to Bourke, and from Bourke to Walgett and the Barwon.

its bed

1609. What is the character of the river-bed? Alluvial, with occasional rocky bars.

1610. What was about the average width of the banks? I have never measured them.

1611. What are they at the flood-level? I would think they were about 300 or 400 feet.

1612. And at the bottom? 150 feet at the outside.

1613. What would be the average depth of the banks at summer level? I do not know; it is scarcely a fair question, but I would roughly estimate it at about 30 feet.

its summer level:

1614. What do you call summer level in the Darling? Lowest running level.

1615. What is the lowest summer level? Just before it ceases to flow; it cannot be referred to any standard datum.

1616. It ceases to flow in summer-time? I believe it does, but I have never seen it in that state.

at Wentworth:

1617. What is the lowest you have known the summer level of the Darling to be at Wentworth? That I could not tell, because there is a considerable depth there, and it is difficult to say when the river is flowing or not.

at Menindie:

1618. At Menindie? The lowest I have seen there is about 3 or 4 feet. These answers are not from measurements, but are merely guesses at truth.

at Wilcannia:

1619. At Wilcannia? I have seen it there so low that you could walk across the river on the rocky bars, where it might have been 6 inches.

1620. What would be the breadth there? At such a time the water would be flowing only in the lower gaps of the bar.

1621. About 10 or 20 feet? I would not venture to answer.

its fall.

1622. You know the average fall of the Darling? I believe it is about 3 inches in a mile.

1623. Have you seen the Murray at the junction of the Darling? Yes.

1624. Have you seen it at flood-time? Not in full flood, but I have seen it at about half-flood.

1625. Did it appear to raise the Murray water at all—was the water in the Murray higher below the junction than above it? That I could not tell, because I did not take any levels, and could not perceive the small amount of difference that might possibly exist.

Drainage from Lake George.

1626. *President.*] Do you know of any levels taken in the drainage from Lake George? No; I heard there was a scheme afoot to drain it.

1627. You cannot give any information about the levels? I believe the promoters have been furnished with that information by their engineer.

1628. Have you any further information to give the Commission before closing you evidence? I think not.

Extension of tank routes.

1629. *Mr. Franklin.*] Have you any conceived plan for any lines for the extension of tank routes through the country? The lines are not fixed by my Department, but by the Stock Branch of the Mines Department.

1630. From experience do you know which particular lines of the country you would recommend for fixing tanks? It is not a matter coming under me for consideration—it is vested in the Stock Branch, and they have always dealt with it.

Machinery for excavating tanks.

1631. In excavating these tanks what machinery do you use—is it the practice to use steam scoops? We have a steam scoop at work near Nymagie, but most of the work is done by the ordinary bullock plough and scoop.

1632. You have not adopted any machinery used in South Australia? No; it seems to cost as much to work with steam as with animal power.

1633. Can you sink to an equal depth at the same cost? No; up to 18 feet we can, but beyond that I believe the steam plant lessens the cost.

Slopes of tanks.

1634. *Mr. M'Mordie.*] They have to work a very flat slope? Yes; supposing an oblong tank is being excavated, the long sides would be given slopes of (say) 2 to 1, and the end slopes, up and down which the scoop entered and left the tank, would be given an easy slope of (say) 5 to 1.

Loss of water through flat slopes.

1635. *President.*] I understand that that is an objection? Yes, unless you intend to water stock in the tank instead of in troughing supplied from the tank by pumping. All shallow water evaporates more readily than deep, hence flat slopes are a source of loss.

1636. You consider that a tank should never have a greater slope than to ensure the banks not giving way? Most decidedly.

1637. *Mr. Franklin.*] Would there be a great saving in using steam appliances if we were excavating on a large scale without refinement in the slopes? I think so, where there was a great amount of concentrated work.

THURSDAY, 9 OCTOBER, 1884.

Present:—

MR. BARTON, M.P.,	MR. LYNE, M.P.,
MR. DONKIN, J.P.,	MR. MURRAY, M.P.,
MR. FRANKLIN, C.E.,	MR. M'MORDIE, B.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Cecil W. Darley called in and examined:—

Mr. C. W. Darley. 9 Oct., 1884.

1638. *President.*] What is your profession? I am a civil engineer.
1639. You are principal Assistant Engineer of the Harbours and Rivers Department? Yes.
1640. You visited America a short time ago? Last year.
1641. You received instructions from the Government? I was asked, in passing through, to look into the subject of boring and drilling—to see how it was done there, with the object of presenting a report upon the subject.
1642. And you have presented that report? Yes.
1643. It has been published in pamphlet form, I believe? Yes; I have distributed copies to members of the Commission. (*Appendix* J 1.)
1644. In this pamphlet have you dealt with any subject apart from the system of boring in the United States? No; simply with boring and drilling.
1645. And the whole of the information which you obtained while in America is contained in the pamphlet? On that subject.
1646. Did you obtain any other information which would be of service to the Commission? I think not.
1647. Did you obtain any information as to the storage of water? No.
1648. Nor upon any system of irrigation on a small or large scale? No; I did not go to any irrigated portion of the country but California. That I refer to in my report.

Resemblance of country in California and in Australia.

1649. Is the country which you visited at all like Australia in its natural features? I think so; that portion of California which is contained in the San Joaquin Valley is very like. It is a dry, level tract of country, with mountains on either side. It is bounded by the Sierra Nevadas to the east, and the coast range lying between the valley and the coast. It is a wide valley. Ordinarily the rainfall is only from 8 to 10 inches in the year. Before they adopted a system of irrigation this country was almost valueless; five years ago the land was to be purchased for about 1 dollar an acre.

Value of land since irrigated.

1650. What is its value since it has been irrigated? It has gone up to from £50 to £60 an acre.

Irrigation from wells and by canal.

1651. Is the irrigation carried on by means of wells? It was first carried on by means of canals from the heads of rivers. The Canal Companies commenced in this way, but they have now covered as much country as they can with the quantity of water at their disposal. Now the landowners are extending the irrigation by means of wells sunk over the whole area.

Private enterprise.

1652. In carrying out this system of irrigation did the Government enter into a contract with Companies? No, it was done entirely by private enterprise.

King's River Company.

The Government gave to certain parties the right to take the water. For instance, there is the King's River Company; they have a right to tap the river, and they took every drop out of its bed and brought it down by means of canals above the banks. A portion of the water is brought down in flumes. There is a good deal of pine country at the head of the river, and there are saw-mills there. The water in these flumes is made to carry down the timber. The flumes are V-shaped, and the water after bringing the timber down to Fresno is used for irrigation purposes. The greater part of the country is irrigated by means of canals from the head of the King's River. The Company have a right to the water, and they lease it to landholders. They have a system of leasing; they can grant a ninety-nine years' lease, undertaking to supply the water for that time.

Regulations.

1653. Is this provided for by legislation? Yes. I had not time to go into the matter very much, but I would suggest that you should send over for the Act and particulars of one of these Companies; you would then be able to see their regulations.
1654. *Mr. Franklin.*] What would be the best Company to send to? I think the Company called the King's River Canal Company.
1655. *President.*] Do you know whether the Government let any water rights? I do not think so—I do not think they interfere.
1656. Do they give any rights to the land? Not in this district; all the land is purchased, and the parties arrange with the Canal Companies; but, as I have said, they have let out all the water they have.

Irrigation by artesian water.

An enormous area of country is being irrigated and brought into use by means of artesian water.
1657. Is that done by private enterprise? The farmers contract with a number of contractors; they contract to put down a bore for so much, guaranteeing the water. A blacksmith named Mull is one of these contractors. It is done entirely by private enterprise—the Government do not interfere at all.
1658. Is the country in which this system is carried out a level country? Yes.
1659. Does the water rise above the surface when it is struck by these bores? Yes. The holes are cased; when water is found they stop the case and cut it off about 4 feet above the surface. In some cases I have seen the water 3½ inches deep over the lips of the case. If you refer to plate 10 in the pamphlet, you will see an illustration of the method adopted for impounding and distributing the water at the surface. They form an earthen embankment enclosing a few acres of ground, the tube being in the centre. The water flows until it reaches the top of the embankment, and it is then conveyed in various directions by means of elevated ditches. The farms are divided into what they call "checks." Each of the checks is levelled off.
1660. Have they a system of draining the water over the surface of these checks? The water is simply stopped at a certain point, and the ground being porous it disappears.
1661. The soil is of a sandy nature? It is very productive. In its natural state it will hardly grow grass. It is a great bare wilderness, with little tufts here and there of a brush similar to that which is found in our salt-bush country.
1662. Is it necessary to expose the artesian water to the air before it is allowed to go over the land? I do not think it is necessary. The water is stored and conducted to the portion of land to be irrigated in the

Mr. C. W. Darley. 9 Oct., 1884.

the manner I have described. They can store several days' supply. I saw plenty of cases in which the water was wanted for pasture land, and in which the water was allowed to run directly over the surface—there were no flumes.

1663. I suppose the system could be carried out by pumping up the water? Yes. Over a great deal of the country they have water at two levels. In one case they find the water at about 40 feet below the surface. That is not artesian—that is, it will not rise above the surface—but it is abundant and fairly good. It is not the best water. Below this level they pass through an impervious stratum for about 250 feet, and they then get into another gravel bed, where they tap water which is artesian. On many of the small farms in the valley hundreds of acres are under fruit; there are apple and plum orchards and tomato gardens. There they have not gone to the expense of sinking to the lower water—they are satisfied with the upper water. They put down a tube well in a few hours, and it can be done at a trifling cost. One man told me that he had put down three or four in a day. They put on a windmill and pump up the water. The water is run along to the roots of the trees. They have tanks for storing, and if they are not using the water they lay off the windmill. In a certain part of the year they require to run the water along the roots of the vines, especially during the first two or three years of their growth. Pumping of water by windmills.

1664. It is a vine country? Yes. I visited one vineyard which had just been started by a Mr. Barton, close to Fresno. (*Appendix* J 2.) He had taken up 640 acres about five years before I was there. When I visited the vineyard he had 500 acres under vine. The country when he took it up was exactly like the country to be seen outside of his fence. His vineyard was a little oasis in the desert. He had water from the King's River Canal Company. Outside the country was sandy, and was covered with little burrows. There are a vast number of ground squirrels—they occupy all the country. There are also rattlesnakes and owls frequenting the same vales, but the irrigation drives them all away. Mr. Barton had about 100 acres laid out in checks for green crops; the finest crop of wheat I ever saw was growing there. Mr. Barton's irrigated vineyard.

1665. *Mr. M'Mordie.*] What is the area of these checks? It depends largely upon the contour of the ground. If you have much slope, you must make them small and get them nearly level. Mr. Barton's were about 400 feet square. His country is pretty level; some were 500 feet. The wheat was growing in checks, some of which were about 600 feet by 400 feet. Area of checks

1666. *President.*] Have you had much experience as a traveller in Australia? Not in the dry country.

1667. Do you think the nature of the country corresponds sufficiently to enable the same system of irrigation to be carried out in both places? From the descriptions I have heard of the Paroo and Warrego country, I should say it was very similar to the country in which this irrigation is carried on. Certainly it is not so near to the mountains as the country in California. There they know where the water comes from. There the Sierra Nevadas are immediately above, and they are snow-capped throughout the winter, storing up the water for the summer supply. Californian irrigation system adaptable in Australia.

1668. A great deal of the water is snow-water? Yes, there is a natural reservoir on the heights of the Nevadas. The water sinks down and finds its way to the sub-strata. There must be a vast quantity of water sinking down in this Colony—it is well known that the rivers do not carry off the rainfall.

1669. As far as your experience goes, do you think that the river-water could be distributed in the manner you have described? I do not think so. I do not feel myself qualified to give an opinion on the matter. The country I think is too great in extent; you might distribute the water over a small area near the heads of the rivers; I think you would not be able to carry the water the necessary distance. You may be able to do something near the heads of the rivers—at the head of the Gwydir, for instance. Distribution of river-water.

1670. Is the system of boring in America very complete? Yes, they have brought it to great perfection. Price of boring in America.

1671. Have you given in this pamphlet any estimate of the cost? Yes, I have given the prices of two or three machines.

1672. And the price per foot for boring? Yes.

1673. *Mr. M'Mordie.*] What is the rate of wages paid there? It is as nearly as possible the rate which we pay here.

1674. *Mr. Murray.*] And they employ white labour? Yes. There are standard rates for boring throughout the country. The rates which rule in California rule also in Colorado, where I also saw some boring going on. You will find the rates stated on page 22 of my report. The first 100 feet will cost 2s. per foot; from 200 to 300 feet the cost is 3s. per foot; from 300 to 400 feet 4s. a foot, and so on, making the cost for boring a hole 600 feet deep, £102 10s. To that, of course, you must add the cost of casing.

1675. Would that be great? It costs about 3s. a foot, making the cost for 600 feet £90. There it is the practice for the farmers to board the men who do this work. Say there are three men employed for six weeks at 2s. per day, the cost would be £12 12s. The total cost of a 600-feet hole would thus be £204 2s., or 6s. 10d. per lineal foot. They would start with a 7-inch drill; but it is not often that you can get a 7-inch casing of thin sheet iron deeper than 300 feet—the friction is too great, and it is apt to be crushed. They would stop the 7-inch casing at about 300 feet and continue with a 6-inch case. When the 6-inch casing reached the bottom, and upon completion of the bore, it is cut off a few feet above the bottom of the 7-inch casing and the upper portion withdrawn to be used again. It appears to be a 7-inch hole, but in reality it is only 7 inches for 300 feet. The secret of getting the water is to be found in the casing. They bore in some parts of the country without the casing, but they do not get artesian water. The same thing is overlooked in this country. I have heard of water being tapped at a low level rising up to a certain height and not flowing any more. If the hole had been cased the water would probably have risen to the surface. In California they meet with a permeable stratum at about 40 feet below the surface, and below this again an impermeable clay for about 250 feet. They bore inside the casing. A steel shoe is put at the bottom, and they make it cut its own way down, removing about a quarter of an inch all round the hole. That makes the tube get through the impermeable strata till they come to good water below. Suppose they did not case the hole right down, the water would rise to a certain point, but it would disperse with the upper water. Casing.

1676. They obviate that difficulty by putting the casing right through it to a particular depth? Yes. The words "boring" and "drilling" have a distinct meaning; in that country they bore in the alluvial country, and in the rocky country they drill. The case is put well into the rock, and it thus cuts off the upper water. I explained the process in my report.

1677. *Mr. M'Mordie.*] Did you look at the canal irrigation at Colorado? I had no time to study it, but I saw some of the canals.

1678. *President.*] Do the farmers incur any risk in these contracts—suppose the contractor does not find the water? They have bored sufficiently to know exactly where to find the water; the contractor takes all the risk of getting the water. Arrangements with contractor.

1679.

Mr. C. W. Darley. 9 Oct., 1884.

1679. And of breakages? Yes, of everything. If he does not get water the farmer does not pay. I saw some holes which had failed, and in which the tubes had been crushed. The price pays the contractors handsomely—I could see that from the eagerness with which they were competing for the work. In some cases I believe they did the boring for a third of the prices which I have quoted, thus making a profit of two-thirds of the contract rate for boring. I saw a place near Stockton where a bore was being put down by means of the hydraulic boring apparatus. The work was very rapid. The man had been upon the ground twelve days with his machine. He had a steam-engine for pumping and running the machinery. His book time showed eleven days and three-quarters, and the tube was then 524 feet below the surface. In that time he had had to erect his machinery and put down a well 40 feet to get water for his engine; and he had had to make his tank. There must have been two days' preliminary surface work before he got his machine started.

Hydraulic boring.

1680. Was it soft sinking? Gravel and alluvial. When I was there he was going through a gravel-bed, and was washing up stones the size of walnuts.

1681. Where did he get his water from? He had to put down a well.

Appliances used in California suitable in Australia.

1682. Considering that the wages here are similar to those paid in the United States, that the country is similar, and that the rainfall is similar, I suppose that the appliances used in California could in many instances be brought into use here? I think they are admirably suited to this country. Some of the machines have hand gear. Then there is horse power, which I should recommend for this country.

1683. You would recommend that in sinking, especially for artesian water, there should be boring, not open sinking, and that it should be tubed? Yes, there certainly should not be open sinking.

American makers of appliances.

1684. *Mr. Franklin.*] Do you know of any firm in America who have devoted their attention to the making and improving of these appliances? Yes, I know two at least—the Gillespie Tool Company and the Pierce Well-excavating Company.

1685. They are acknowledged to have the best boring appliances? Yes, they have about the best. I may mention that the tiffen is only used for the surface water.

Good opening for mechanics in this country.

1686. *President.*] Do you think it would be economical on the part of the Government or of private individuals to enter into a contract with any of these Companies in America? I think there is a good opening for an intelligent man with a little capital—a good mechanic. I noticed that the whole of the men working these machines were mechanics, chiefly blacksmiths, who could mend their own tools, or who, in the case of emergency, could make tools for a particular kind of work. A man of that kind, with sufficient capital to obtain the plant, would make a certain fortune, I think, in this country, by contracting with people to sink holes.

1687. *Mr. Donkin.*] It would be necessary that they should be practical men in this Colony, because they would have to work in such isolated places? Quite so.

Crops produced.

1688. *President.*] What are the crops which the farmers produce on this irrigated land? It is so suitable for fruit-growing that they are devoting it to that purpose as much as possible, but I saw some good crops of lucerne; they also grow splendid crops of barley, oats, and wheat; here and there you will find a man with as many as 100 acres of tomatoes.

Annual rates paid to the Flume Companies.

1689. *Mr. Barton.*] Do you know the quantity of water used per acre for this irrigation? The water is sold by the Flume Companies at 5 dollars per annum rent.

1690. Is that per acre? Per acre; and 100 dollars per foot—that is, a miner's foot. A miner's inch is an inch of water discharged through a notch 1 inch square in a 2-inch plank, and under 6 inches of head. A miner's inch will discharge 2,267 gallons in twenty-four hours. A farmer would be entitled to just twelve times the quantity for a foot.

1691. *President.*] Is that the system of gauge adopted for distribution? Yes.

Gauge of water used.

1692. What is the gauge to ascertain the quantity of water used? It is very rough; the quantity is guessed—they do not measure it at all. In the first few years the farmer will probably use more than he is entitled to, but afterwards he will not require to use so much as the quantity to which he is entitled. They know that, and the quantity used therefore is not gauged.

Discharge of water from the flumes.

1693. Supposing the flumes passed through country where irrigation is required, in what way do they discharge the water from the flumes into the distributaries for watering the land? They bank up the flumes, and they have ordinary wooden sills which pull up.

1694. *Mr. Barton.*] You do not know the quantity of water they use for their crops—that is, the quantity used for each irrigation? I did not go fully into that.

Salt deposits.

1695. *Mr. Franklin.*] Did you hear any complaints of a salt deposit on the irrigated land? No.

Total cost per acre per annum for irrigation.

1696. *President.*] Do you know the total cost per acre per annum for irrigation? As I just now said, it comes to 5 dollars an acre rent per year, and 100 dollars per foot of water per section. It takes 4 feet, at 400 dollars, for the 640 acres, or £80 for a section; adding the 5 dollars per annum rent, the cost would be £1 3s. an acre.

Fluctuation of discharge from the wells.

1697. Do you know whether there is any great fluctuation in the discharge from the wells in the San Joaquin Valley? It comes pretty steadily. I asked some of the farmers whether upon putting down a second well pretty close to one which was already running it would slack off the supply from that well; but it appears that the supply is not stopped—it seems to run pretty constantly.

1698. Is it pretty regular in all seasons? It is pretty regular, I believe, all through the year.

Distance between wells and water soakage area in the hills.

1699. Is the distance known between the wells and the outcrop of the water-bearing strata on the hills? I think they have the information, but I was not able to get it. There was an elaborate report in reference to that portion of California. I thought that I should be able to obtain a copy in the Colony, and I did not bring one away with me, but I find that the only copy in this Colony was burned in the Garden Palace fire.

1700. Have you any idea of the distance? I suppose it would average from 10 to 14 miles to the hills—That is from the places where they get the artesian water.

1701. *Mr. Donkin.*] What is the greatest distance away? There are parts of the country when you go south—in Texas for instance—where the hills are some hundreds of miles away from the nearest place at which they get artesian water.

1702. *President.*] How long is it since they first discovered this artesian supply in the San Joaquin Valley? About three or four years ago.

Results of shallow sinking.

1703. Did you obtain any information as to the result of the shallow sinking—that is, before they adopted the system of casing, when the sinkings were open—had they any difficulty then in obtaining permanent water? I do not think they ever attempted the open sinking.

1704.

1704. I suppose they would not have obtained a constant supply? The upper water, as I have already explained, does not rise to the surface—they have to pump it. Looking out of a railway carriage window passing through parts of the country, one may see in some cases probably 100 windmills at one view. Mr. C. W. Darley. 9 Oct., 1884.

1705. You did not hear that in any case before adopting the casing of wells they sank to the depth to which they are now sinking for artesian water? No.

1706. What was the deepest well you saw? In California about 550 feet; I saw some afterwards 1,200 and 1,400 feet. Deepest wells sunk by drilling.

1707. Were they sunk by boring? No; I saw one put down at Oaklands by drilling to a depth of 1,400 feet.

1708. What machinery was used? The Pennsylvania rig. Machinery used.

1709. Are you aware whether the Canal Company of which you have spoken obtained any concession of land? I do not think so. Income of Canal Companies.

1710. They obtained the whole of their income by disposing of the water? Yes.

1711. Does it seem to be a prosperous Company? I could not find out much about it except what Mr. Barton told me; they seemed to be doing pretty well.

1712. *Mr. Donkin.*] You think that there ought not to be a great difference in the contract prices for boring and drilling between the two countries? I do not think so. Contract prices for boring and drilling.

1713. At present there is a contractor in Sydney who has put down some twenty wells, averaging from 50 to 200 feet—he charges 15s. per foot for tiffen boring? I should say either that he made a great deal of money or he did not know his work, or that he must have bad tools.

1714. The Pierce Company say that they will bore to 3,000 feet at a charge of £2 a foot? Of course the price increases as you increase the depth, but in their own country they bore at a much less cost than that. I would refer you to the pamphlet issued by the Gillespie Tool Company, which I will put in as an exhibit. (*Appendix* J 3.) I would suggest that a man—that is a competent mechanic—with a machine, should be obtained from both the Gillespie Tool Company and from the Pierce Well-excavating Company. If both Companies were competing, they would take care to send a first-class machine and a first-class man in charge of it.

Mr. Thomas Kingsmill Abbott called in and examined:—

1715. *President.*] You are a Stipendiary Magistrate? Yes. Mr. T. K. Abbott. 9 Oct., 1884.

1716. You are at present residing in Sydney? Yes.

1717. But formerly at Gunnedah? I lived at Gunnedah from 1867 to 1882.

1718. When you were living there, I believe you took considerable interest in obtaining particulars in reference to the wells sunk in that district? I collected some information respecting wells in the county of Pottinger; I could not get information as to the whole district. Information on wells in the county of Pottinger.

1719. Then the information which you have obtained is confined to one county? Yes.

1720. After obtaining this information you wrote a paper, I believe, which was read before the Royal Society? (*Appendix* K 1.) Yes, by Mr. Russell.

1721. That was in 1880: did you afterwards follow up your inquiries, or did you obtain any further information which would be of use to us? No, I do not think I have much more information. I have some information about a few wells in addition to those mentioned in the paper. You will see that it has a map attached to it showing the position of the wells. (*Appendix* K 2.) I think I have obtained information about twenty or thirty more wells, a few in the counties of Nandewar and Buckland.

1722. What is the nature of the county? The county of Pottinger consists of plains of black soil. Nature of soil in county of Pottinger.

1723. Is it hilly or level? The plains are nearly all level, or there are only slight undulations; there are basaltic mountains running through the district.

1724. Over what extent does your information extend—how many miles? The extent of country would be about 80 miles by 90.

1725. Nearly 100 miles square? Yes.

1726. Were there any artesian wells there? Several. No. 20 at Bando is one. Artesian wells.

1727. That is an open well, that is it is not cased in? It is slabbed.

1728. But not watertight? Oh no.

1729. Has it been ascertained where the water comes from in great distances? The well is situated on the slope of a basaltic range, and further on on the same slope to the southward, there is a place called Tambar Springs where the water comes to the surface. To the north there is a place called Garrawilla, where the water also comes to the surface. Tambar Springs.

1730. In these cases the water is artesian? Yes. At Garrawilla it is a spring. There is a dam filled by it which washes about 50,000 sheep. No. 58 is also a well in which the water flows over the surface. Garrawilla Spring.

1731. *Mr. Franklin.*] I observe from the map that there is a range of hills on the western side of this area? This map is taken from the county map on the scale of 2 miles to the inch. The range marked really represents no very perceptible rise. In different places there are high mountains, but between Cox's Creek and the Castlereagh the ridge dividing the fall of the water is almost imperceptible. The range dividing the waterfall.

1732. *President.*] What is the height of the range above the spot where the water appears? Do you mean at Bando? Its height.

1733. Yes, what is the height there? The highest point is 600 or 700 feet above the well itself, and the well is about 50 feet above the level of the plains, that is, above the banks of Cox's Creek.

1734. Do I understand you to say that the range is about 600 feet above the well? Yes.

1735. What is the nature of the soil? Black soil, and the range is broken basalt. Black soil and broken basalt range.

1736. In sinking the well did they go through black soil all the way? There was pipeclay at the surface, but the strata was unknown. The well overflowed fourteen or fifteen years ago in consequence, it was said, of ringbarking. That is all the information I could obtain about it. Pipeclay.

1737. *Mr. Donkin.*] What depth is the well? 90 feet.

1738. You do not know what underlies the black soil there? No.

1739. Do you know the difference of the level between the surface of this well and the summer level of the Namoi River? I could not say. I should think it would not be more than 90 or 100 feet. Difference of water level in the well and in the Namoi.

1740. Do you know the height of most of the wells in the district? You mean as regards the plain?

1741. Yes, what would it be? I know the position of every well marked on the plan—I have been to nearly every one of them.

1742.

Mr. T. K. Abbott. 9 Oct., 1884

1742. Do you know the height of the well above the sea-level? I could give the height of most of the wells with regard to the level of Gunnedah, and that is about 890 feet above the sea-level.

1743. And you know the respective heights of the wells as regards Gunnedah? Almost all of them.

Height of wells above sea level.

1744. Is there any great difference between the height of the various wells as compared with each other? There is a considerable difference. No. 2 is at the head of Ulaman Creek; that would be about 100 feet higher than No. 20 at Bando. The springs at Tambar on the side of the mountain are 200 feet higher than the plain.

Discharge of water from Tambar Springs.

1745. Is there any great discharge of water from these springs? About 400 to 600 gallons an hour; it runs across the road. The water discharge varies according to the weather; in dry days it almost ceases to run—in damp dull days it runs strongly.

1746. A letter was written a short time ago to the Under Secretary for Mines and referred to us, in which it was stated that a spring, I think somewhere in that neighbourhood, was affected by the moon: do you know whether these springs or any other springs in the district to which you refer are affected in that way? I never heard of it.

Lunar and atmospheric influence on the wells.

1747. But they are affected if the atmosphere is moist? Yes, there is a marked difference in the spring between moist days or dull days and on bright sunshiny days.

1748. *Mr. Donkin.*] It has been said that the moon in a certain position has a certain influence upon the level of the water in one of these springs: have you observed any influence of that kind? I never noticed it.

Height of the wells in comparison with the level at Gunnedah.

1749. *President.*] You say you know the height of most of the wells comparing them with the level at Gunnedah: what is the average height of the wells going right through the whole district? Do you mean the height of the surface?

1750. I mean the height above Gunnedah? Some of them would be lower than Gunnedah, but there are so many wells that it is difficult to take an average.

1751. Would there be any great difference between them? Not a great difference. In the case of all the wells on the Breeza Plain the surface would be only a few feet higher than Gunnedah. They would range, I suppose, from 850 to 1,150 feet above the sea-level.

The Namoi River.

1752. Are you well acquainted with the Namoi River? Yes, I have been along the Namoi.

Nature of the bed.

1753. What is the nature of the soil in the bed? It alters as you proceed down stream; the further you go, the finer and softer the soil becomes. At Gunnedah the bed of the Namoi is gravel; at places there are large boulders which have been brought down from above.

1754. It gets softer as you go to the Darling? Yes, above Carroll it enters the mountains; there it changes its name—it is called the Macdonald.

Natural places along the Namoi for storing water.

1755. Are there any natural places along the Namoi where by diverting the water or by making weirs or dams any quantity could be stored? I do not know of any place beyond Narrabri—that is, between Narrabri and Walgett—where it would be possible to make a weir. I say so because of the fineness of the soil and the readiness with which it would dissolve. The water running along the end of the weir would sweep it away in a short time.

1756. Suppose it was an overshot dam, the water would then go over the top? It would excavate so much below that eventually the dam would be probably carried away.

Dams and weirs.

1757. Would it not be possible to overcome that difficulty? I think the great difficulty in making dams or weirs on the Darling would be found in the exceeding fineness of the soil; it is an alluvial deposit of the finest character—if you take up soil in your fingers, it will dissolve away like soap if wetted. The Namoi in flood-time carries away such an enormous quantity of water that an obstruction of that kind might divert the course of the river. It has parallel rivers in places. The Darling, for instance, has billabongs running parallel to it for hundreds of miles.

Holding ground between Peel River and Carrol.

1758. *Mr. Franklin.*] Between the junction of the Peel and the town of Carrol is there any holding ground? Yes, I think so.

Nature of soil.

1759. What is the nature of the soil? It is chiefly basalt. Sometimes there is a sort of pebbly conglomerate with ridges running into the river. The flats about the Peel and the Namoi are alluvial.

Rapidity of stream.

1760. Is the stream very rapid? About and above Carrol it is; from Gunnedah it is slow. I never measured the rate.

Suitable place for a dam at Tulcamba.

1761. Do you know of any point in the neighbourhood mentioned where, by putting a dam across the river, any large quantity of water could be stored? Yes, I think there is such a place at Tulcamba.

1762. About what would be the height of the weir or dam required? I could not say the exact height; I should think about 30 feet or more above the water-level.

Area covered with water by the dam.

1763. *President.*] What area would that cover with water at the back? I could not say exactly; it would throw water back for several miles I should think.

1764. About how broad would be the area? It might be in one part half a mile or more broad? The place to which I refer is a spot at which two hills come close together.

1765. It is a kind of gorge? Yes.

Difference of elevation between Tamworth and Gunnedah.

1766. *Mr. Franklin.*] The Peel River is pretty rapid? Yes; there is a difference in the elevation of Tamworth and Gunnedah, which are about 50 miles apart, of 300 feet. The principal difference in the elevation is between the junction of the Peel and Tamworth. Of course the fall is the greatest where the river is the most rapid.

Storage of water on the Warrilla.

1767. *President.*] Are you acquainted with any other places in which the storage of water could be carried out in that district? I think it could be carried out on the Warrilla, a tributary of the Namoi.

1768. Much in the same way? Yes; there are a number of places on that river where water could be stored.

Distribution of the stored water.

1769. *Mr. Franklin.*] But supposing you stored a large quantity of water in that district, what would be the natural drainage—are there any obstructions to the cutting of tributaries or canals? The water stored there would have to be brought parallel to the course of the river for some distance.

1770. You are not aware that any levels have been taken there? I do not think so.

Wells on Breeza Plains.

1771. *President.*] You have marked a number of wells on the Breeza Plains? Yes; they are or were intended for improvements on selections.

1772. They are close to each other? Yes; the plain from Gunnedah to Breeza is about 22 miles.

1773. Do you suppose that these wells are tapped from separate underground channels or from one source?

Old stream of the Mooki.

I could not say; I think the course of the old stream of the Mooki might be traced back along the edge of the timber. The water was found under similar conditions—in sand, through which it has evidently percolated, because it was perfectly fresh.

Mr. T. K. Abbott. 9 Oct., 1884.

1774. Is it found in sand in all cases? Oh no—in some cases it is found in clay; in those cases it is invariably salt. If it is found in rock it is usually brackish.
1775. That would lead you to the conclusion that the water found in these wells does not come from the same source? I should say not.
1776. But wherever the water is found in sand, and is fresh, you are of opinion that it does come from the same source? I would not say that. I could not say that that is the case wherever the water is found fresh, because it is obtained at different levels and under different circumstances. In nearly all cases in the county of Pottinger it is fresh when it is found in sand, especially loose sand or gravel. Of course that points to the conclusion that the water percolates through the gravel. In the case of well No. 58 the water flows over the surface immediately at the foot of a basaltic hill, an isolated hill several hundred feet high. In the case of No. 57 the bottom of the well is 200 feet lower than the surface of the well at 58, and there is no water in it. It was sunk through red clay the whole distance.

Source of water in the wells.

1777. Has it ever been proved whether pumping or the raising of water from any one well in a large quantity affects the other wells in the neighbourhood? I do not think so; I have not heard of it, nor have I seen any proof of the kind.
1778. Do any wells fill quickly if they are reduced in quantity? In some cases; in other cases they fill slowly. There are two extraordinary wells at Moredevil Station, at the head of Bundella Creek. Many years ago a well was sunk to a considerable depth—I believe it was about 80 feet. No sign of water was obtained before this level was reached, when, as the workmen broke through some hard rock, the water rushed in so rapidly that they were compelled to abandon their tools and make good their escape by means of a rope and windlass. In a few hours the well was filled to within 10 feet of the surface. When this well exhibited symptoms of caving in another well was sunk about 80 yards easterly from the first. That was 100 feet deep, and was situated higher on the slope by 4 or 5 feet. When the bottom was reached the water came as rapidly as in the case of the first well, and rose to within 4 feet of the surface. On the following morning the first well had overflowed, and a strong stream, amounting to upwards of 300 gallons per hour was flowing from it. This has since continued through all kinds of seasons without cessation. The water is conveyed from that well in pipes for some miles. It is quite sufficient to water a whole station; it is close to the main range. Some information was given to me by the Manager of the station. He tells me that the first well is 6 feet by 6 feet, and is situated within 20 yards of the spring where, as a rule, water is on the ground. On one occasion they took out 5 feet of water, and the well rose 30 inches in 50 minutes. He tells me that after taking out 12 feet of water the water rose much more rapidly than it did at the higher level.

Two extraordinary wells at Moredevil Station.

1779. If the first well had been cased I suppose the water would have come to the surface in the first instance? I think in all cases where water rises rapidly it would come to the surface if it were prevented from escaping through loose strata.
1780. Have you had experience in any other part of the country? I have never had much experience, but I have been through the Colonies from South Australia to the Gulf of Carpentaria.
1781. That is many years ago? Yes, in Queensland; the others more recently.
1782. There nothing has been done in the way of sinking for water? Nothing at all. I saw some mud springs—there are several on the Barcoo in Queensland.

Mud springs on the Barcoo.

1783. *Mr. Donkin.*] They are principally in Queensland? Yes. There are none, as far as I can remember, from Springsure to Clermont, but there are some on the Barcoo.
1784. *President.*] What was the cause of you taking an interest in this question of wells? Mr. Russell invited me to do it. I took the matter up several years before this paper was written, and I did so because I was anxious to ascertain whether the information I could gather from a limited extent of country would lead to any conclusion as to where the water which fell on the surface went to. I knew that the Darling did not carry it away. I thought that information which I might be able to obtain could be applied to similar country in other parts of the Colony.

Object of the collected information on wells.

1785. After obtaining all this information, at what conclusion did you arrive as to what became of the water? I concluded that the water reached the sea through deposits of sand or gravel in various strata.

Conclusion from this information.

1786. Do you suppose that the water travels any distance underground through this country in this district where the wells are, that is to say, is the source of the water far distant from the wells? I should say 50 or 60 miles.
1787. Do you suppose that the water which falls on the higher country goes underground to any great distance into the interior of the Colony? I think so.

Underground currents into the interior.

1788. It goes to a great distance at a considerable depth? I should say that it continued until it reached the sea at a considerable depth.
1789. Never appearing on the surface? Unless in the shape of mud springs or in the shape of artesian water.
1790. That would be when it was struck? Yes.
1791. Did the result of your inquiries cause you to arrive at any other conclusion in reference to the escape of the rainfall? I think the principal part of the rainfall, the part which cannot otherwise be accounted for by every possible allowance for evaporation, waste, and soakage, can only be accounted for by assuming that it escapes through these underground strata.

Evaporation, waste, and soakage of the rainfall.

1792. You do not suppose that most of the water or any large proportion of it gets away in evaporation? A large proportion does.
1793. But not a larger proportion than has been asserted by Mr. Russell and others? I do not think so. I think that Mr. Russell's conclusion is more nearly correct than any other I have heard of.
1794. That would leave a large proportion to get away in the manner you suppose? Yes.
1795. You have not followed up these experiments elsewhere? I have not.
1796. Will you put in as an exhibit the pamphlet to which you have referred? Yes.
1797. Have you written any papers since? I have not.
1798. In the district in which you take so much interest, have they resorted to storing water in tanks to any great extent? Not to any great extent, because the wells are sufficiently numerous.
1799. They depend principally upon the wells? Yes.
1800. Have they adopted any means of raising the water by windmills? Oh yes; I think in the district of Gunnedah there must be fifty or sixty windmills at work now. When I collected this information there were none. The windmills have increased very rapidly since they were first tried.

Raising water by windmills.

1801. Do you know what windmills are most approved of? The Eclipse and the Althouse.
1802. Have they attempted to irrigate from these wells? No.

The Eclipse and Althouse windmills.

1803.

Mr. T. K. Abbott. 9 Oct., 1884.

1803. The water is simply used for stock purposes? Yes; and in some cases the windmills raise sufficient in the case of the head-stations to irrigate a small garden.

1804. Do you know whether the water pumped from the wells is distributed straight from the surface for the purpose of irrigating gardens, or whether it is allowed to be exposed to the air for a certain time? I do not think the water brought from the generality of wells would be serviceable for the purposes of irrigation.

Use of well-water for irrigation.

1805. You do not think so? No.

1806. Not if it were exposed to the atmosphere for any time? Perhaps if it were stored in tanks or dams it might be afterwards used, but I do not think it would be serviceable in many cases if it were taken direct from the surface of the well. I had a windmill of my own from which I watered a small garden. I allowed the water to spread over the surface, but it did no good; it left a white sedimentary deposit on the surface, and caused a growth of vegetation which I had never seen before—a growth quite foreign to the district.

1807. Did you ever know water from one of these wells to destroy vegetation? No.

1808. *Mr. Donkin.*] Why do you think that the water would not be serviceable for the purpose of irrigation? I think that in most cases it contains chemicals—salt, or soda.

Effect of ringbarking.

1809. Do you think that ringbarking has anything to do with increasing the water supply? There has been no ringbarking worth speaking of in the county of Pottinger, but I think it does increase the surface water.

Diversion of water from the Namoi.

1810. Are there any anabranches of the Namoi by means of which water could be diverted from the main river? There are some near Narrabri, but none near Gunnedah. The channel is marked.

1811. There are no instances of which you know where, by putting a weir across a river, the water could be diverted by any natural channel? No.

Waterhole near Turrawan.

1812. Not till you get below Narrabri? No. There is one point of the Namoi, near Turrawan, where there is a waterhole 6 or 7 miles long; I think it is 20 or 30 feet deep in places. It occurs immediately after a dyke of sandstone crosses the river.

1813. Do you know that remarkable mud-spring to which Mr. Russell refers, near Gilgoin? That is the spring which contains fossils.

1814. Do you know that? No; it has been described by my brother.

1815. *President.*] The only place you can think of for the conservation of water in the county of Pottinger would be that which you have indicated, and you would conserve the water by the construction of a weir in that case? That is the only way, I think; but it is in the county of Nandewar, not Pottinger.

1816. *Mr. Murray.*] Most of the land in the county of Pottinger is alienated, I believe? All that is of any value.

1817. Do you remember the drought of 1876—I believe your district suffered very much? Yes.

Suggestions to prevent effects of drought.

1818. Could you suggest to the Commission any practicable way of guarding against such an occurrence in the future, that is, speaking from your experience? You mean for preserving the stock in times of drought. I can only suggest that the paddocks in which stock are kept should be made much smaller, and that tanks or dams should be made in such positions that the stock would not have to travel far to obtain water. I believe as a rule they destroy far more grass than they consume in going backwards and forwards for water.

1819. Have you observed in your district the most likely places for obtaining water? It is uncertain.

Water on broken country and on plains.

1820. *Mr. Franklin.*] Do you find it easier to get water on the broken country than on the plains? Along the ridge, at the back of Bando, water can be obtained at a very moderate depth; on the Castlereagh side of the range the country is all scrub and sand. Water can be obtained on either slope.

1821. Then it is easier to get the water in the broken country? I think so. The sinking on the plains is very uncertain. For instance, in a well at Colly Blue about 60 or 70 feet deep the water was so deficient in quality that stock would scarcely taste it. In the case of another well sunk about 15 feet distant, at about one-half of the depth they got an unlimited supply of good fresh water.

1822. *President.*] If the soil is over sand, water can generally be obtained? Yes.

Conservation of water from the Mooki.

1823. *Mr. Murray.*] Is it possible to conserve water from the Mooki? It would be at the head of the Mooki or of Cox's Creek, but not about Breeza.

1824. *Mr. Franklin.*] Do you know of any point for water storage on the Namoi, below the junction of the Manilla? Oh yes. There are many places on the Namoi where in any ordinary drought the river ceases to run; the higher up the river you go the more strongly the water runs.

The Namoi dry between Narrabri and Walgett

1825. *President.*] Does the river appear again further down from the point at which it is lost? Yes, between Narrabri and Walgett it becomes dry, and afterwards you meet it lower down running strongly. I have frequently seen the Namoi dry in many places.

Sandstone at Turrawan.

1826. *Mr. Franklin.*] Are there ridges of impermeable country between these soakages on either bank? I do not think so. There is a place at Turrawan where a dyke of sandstone crosses the river.

1827. Does it appear on both banks? Yes.

1828. How far from the junction of the Manilla? About 70 miles.

Watershed of Cox's Creek and of Brigalow Creek.

1829. Does that sandstone dyke run laterally from the river? It is the ridge dividing the water-shed of Cox's Creek from the watershed of Brigalow Creek.

1830. Is there any settlement on the western side of the range? The country is of no use—it is simply a home for marsupials—you could not ride through it. There is a station there of 100 square miles, but no one uses it.

Eastern slope impermeable; the opposite slope sand.

1831. But water raised on the eastern slope would be valuable? Yes. The country on the eastern slope of the range is impermeable; on the opposite slope it is all sand.

1832. *Mr. Donkin.*] It is your opinion that if any of these western rivers were to be dammed a scour would take place? Yes. The further down the river you go, the greater would be the difficulty in damming it.

1833. *President.*] In the case of the bar on the Namoi of which you spoke I suppose the water flows over it? Yes.

1834. It does not disappear and reappear again? No. Immediately after that dyke there is a waterhol about 7 or 8 miles long, commencing at the bar.

1835. *Mr. Franklin.*] That is permanent water? Yes.

Disappearance of water.

1836. *President.*] From your knowledge of the river, should you say that the water which disappears at any point appears again in the same volume? Yes, it appears to flow again in an equal quantity.

THURSDAY,

THURSDAY, 16 *OCTOBER*, 1884.

Present:—

MR. BARTON, M.P., | MR. GIPPS, C.E.,
MR. DONKIN, J.P., | MR. LYNE, M.P.,
MR. FRANKLIN, C.E., | MR. MURRAY, M.P.,
MR. M'MORDIE, B.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Philip Francis Adams called in and examined:—

Mr. P. F. Adams. 16 Oct., 1884.

1837. *President.*] You are the Surveyor-General? Yes.
1838. How long have you been in the Public Service? Twenty-seven years.
1839. How long have you been Surveyor-General? Since the year 1868.
1840. I presume that you are well acquainted with the interior of the Colony? I have travelled nearly all over the Colony.
1841. Then you have practical knowledge and experience of the inland portions of the Colony? Yes.
1842. Have you ever had carried out surveys of the rivers or any portions of them? The Survey Department has carried out a great many surveys on rivers, but they have not been made with a view to the objects of this Commission. Our surveys show features in plan, without reference to section, falls or levels. Surveys of rivers.
1843. Then these surveys will be of little practical use to us? They will be good plans for many purposes of the Commission, but there are no sections to accompany them.
1844. In a letter which you sent to the Commission you intimated that you could give us a considerable amount of information with reference to the snow-waters of the Colony? I have had experience on both sides of the Snowy Mountains. It is many years since I was on the west side, and I have not preserved the barometer heights which I took at that time. My impression is that if any permanent system of irrigation is adopted in this Colony it must be drawn from snow-waters. The thawing of the snow occurs from October until the end of January, during which time there is an almost unlimited supply of water in one or two rivers, at an altitude sufficient to command some of the most important parts of the Colony. Snow-waters.
1845. What rivers are those? On the east the Snowy River. It is estimated that during the driest part of this year the volume of the Snowy River was 200,000,000 gallons a day. Volume of the Snowy River.
1846. *Mr. Gipps.*] Where was that? The point where the section was taken is about 5 miles above the junction of the main Snowy and Eucumbene Rivers.
1847. At what time of the year was that section taken? It was about June or July last, when everything above was frozen and thaw-water at its minimum.
1848. *President.*] Does the Snowy River discharge into the Murray or the Murrumbidgee? No, it runs into the sea through the Gippsland country in Victoria. The object of my bringing these suggestions under the notice of the Commission is that the water may be used to supplement that of the Murrumbidgee, if for nothing else. The Murrumbidgee has been almost dry when this river was pouring out an unlimited supply. Diversion of water from Snowy River into the Murrumbidgee.
1849. What portion of the Snowy River is within our boundary? The greater portion of it. I think that the longest half is in New South Wales, but I do not think that the fact of its going through Victoria would affect the practicability of the scheme at all, because, during the time that we should be taking out water, the Snowy River is an enormous torrent. It is one of the largest rivers in the Colony—probably it discharges more water than any other river in the Colony.
1850. Are there any barriers between that river and the upper part of the Murrumbidgee which have to be surmounted in diverting the water? A continuous fall could be obtained, but whether the physical difficulties in the course are too great to be overcome I cannot say, because I have not made investigations; I only give you the fact that there is an enormous supply of water, equal to anything which would be required for irrigation purposes, and that such water is available at an altitude sufficiently high to command the dividing range between the waters of the Snowy River and the Murrumbidgee. Having got the water on to that dividing range, it is possible that it may be conducted where it may be desired. Of course the physical difficulties may be too great, but I think there is a possibility of such a scheme being carried out. Barriers between Snowy and Murrumbidgee Rivers.
1851. You said that you had been there? Yes, I have been on both slopes of the Snowy Range, of which Kosciusko forms the summit.
1852. To carry this water in the direction you suggest, would there be any length of tunnel required to get through the range at the head of Stack's Creek? Not that I am aware of. It might not be necessary to make a tunnel or it might, but it is a physical fact that the range at the head of Stack's Creek is lower than the source of supply of water on the Snowy River. Is a tunnel necessary?
1853. *Mr. Gipps.*] What is the height of the point at which you propose to divert the water? 3,200 feet approximately. That is the result of one aneroid observation only. Height of point of diversion.
1854. *President.*] Is there any very great dip in the country between Crackenback Creek and Stack's Creek? Yes, in the valley at the junction of the Eucambene and the Snowy Rivers the height is barely 3,000 feet; that is about 200 lower than the gap at Stack's Creek. Dip of country.
1855. What is the height of Stack's Creek at the gap? It is about 3,200 feet.
1856. That is about 200 feet higher than at the junction which you mention? Yes.
1857. Is the range at the head of Stack's Creek a broad one? I could not say positively; it is my impression that it is, but I have not been over it. I have had the barometer heights taken since I thought of the scheme, but I am not aware what conditions present themselves—that will be a matter for investigation by some one else.
1858. Is the country between Crackenback Creek and Stack's Creek very much broken? Very much. If the scheme which I suggest is practicable at all a large amount of work will have to be done. Broken country between Crackenback and Stack's Creek.
1859. Why is it that in the map which you had before you you have marked such a long elbow down the Eucumbene River as showing the creek's diversion which you suggest? There is high ground to the north of the junction of Eucumbene and Snowy Rivers, and therefore I have marked the diversion approximately where I think it would be likely to go.
1860. Have you any idea of the height at the junction of the Mowomba River? I have not; I have not been there. Height of Mowomba River.

Mr. P. F. Adams. 16 Oct., 1884.

1861. Suppose the elevation of Stack's Creek to be too high to carry the water over the top, can you give any idea as to the length of tunnel which would be necessary to convey the water through the range? Not the least. I think that the cost of a tunnel would be fatal to the scheme—it would be too long. I do not think that there is any danger of not getting height enough to command the gap, because above the point at which the elevation was taken the creek rises rapidly and the amount of water is not sensibly diminished. It is only a question of going higher up the Snowy River to attain the necessary elevation to command the head of Stack's Creek.

Diversion from tributaries of Snowy River.

1862. Do you think it would be possible to connect any of the tributaries of the Snowy River higher up and make the diversion at a higher level than you have suggested? Certainly. The Crackenback has about the same fall as the Snowy River, and by going higher up almost as much water can be obtained as the section indicates, perhaps 40 or 50 million gallons a day.

1863. Can you divert the Snowy River, the Crackenback Creek, or any of the creeks into the Eucumbene higher up to get their water? I do not think so. The reason why I do not think the Eucumbene water would be of much value is because that river falls at a time when the Snowy and the Crackenback are at their highest.

1864. What I mean is, could these creeks be diverted to the Eucumbene higher up? It might be possible but I do not think desirable, because there is plenty of water without going there for it.

1865. But would not the elevation be better? I think not. In my opinion a larger and more reliable supply would be obtained from the Snowy River, and at a higher point than on the Eucumbene. I judge from the amount of snow and superior altitude, but I may be mistaken, as I have not followed the Eucumbene, or looked at it with a view to water supply.

Depressions between Crackenback and Stack's Creeks.

1866. According to your showing, at certain points between Crackenback Creek and Stack's Creek there are depressions? Yes; they will have to be crossed.

1867. Would it not be better, if possible, to divert the Crackenback and Snowy into the Eucumbene at a point where you would get a higher elevation, and thus instead of going round in the way you suggest, crossing Stack's Creek further up? I have not considered that, and I should not like to offer an opinion on the subject. When I travelled through the country it never occurred to me to consider the question which is now before the Commission, and the impressions I have to guide me are those which I gathered on the occasion of my visit—elevations which I took. I do not think it would be advisable for me to offer a definite opinion on the subject, because greater weight might be attached to it than it deserved; besides I have not seen the locality.

Point of diversion on the Snowy River.

1868. *Mr. Murray.*] At about what point on the Snowy River do you suggest that it should be diverted? About 4 miles above the junction of the Crackenback and the Snowy, and about 5 miles from the junction of the Eucumbene and the Snowy. On the 15th February last I saw a stream there infinitely larger than that which I have described—it was so large that the supply was practically unlimited. The water drains the north and east slope of Kosciusko.

Necessary examination of the country.

1869. *President.*] Would you suggest an examination of the country with a view to determine whether it is quite practicable to divert the water as you suggest? Certainly. I think a portion of the Commission should visit the locality, and that a report ought to be obtained from a practical engineer on the subject.

1870. *Mr. Barton.*] Do you not think it would be a wise precaution to take to see the streams at the present time in a season like this, when there is hardly any snow falling? It is not necessary to examine the streams for that purpose, because you may take my word for it that there is more water there than you will ever want. The river is almost unapproachable on account of the quantity of snow thawing. If the Commission visit the river I should advise an inspection in January, not later than the middle of the month. The later you can safely put off the visit, the more important would be the information which you would be able to gather.

Effect of diversion on the Snowy River.

1871. *President.*] Suppose the work were carried out, what effect do you think it would have on the Snowy River? It would not be felt.

1872. That being the case, no great objection could be raised by the Victorian Government? I do not think it possible for them to raise any valid objection. The quantity of water which could be taken by human means would not affect the volume of the Snowy River in Victoria one inch.

1873. Does the Snowy River discharge itself into the Gippsland Lakes above the point of settlement in Victoria? I cannot answer the question—I have never been on the Gippsland Lakes.

The Murray supplied by the Snowy River.

1874. Do you know whether the Murray receives any large portion of the Snowy water from Kosciusko Range? Yes; on the west side of Kosciusko Range the principal affluents of the Murray are the Indi and the Tooma.

1875. Is that the reason that there is a so much larger quantity of water flowing in the Murray during the spring and summer than there is in the Murrumbidgee? This is one reason, but the Murray drains a large area of elevated country in the Colony of Victoria as well as in New South Wales.

Effect of the diversion on the Murrumbidgee.

1876. If the suggestion which you have thrown out to divert a portion of the Snowy River into the Murrumbidgee were successfully carried out, I suppose that the volume of water in the Murrumbidgee would somewhat approach that in the Murray? No; the increment would be limited. I could only suppose that 200,000,000 gallons a day can be supplied. It might be supplied by about 40,000,000 gallons a day from Crackenback, but all the water that could be collected at a higher level than the head of Stack's Creek would not augment the volume of the Murrumbidgee to anything approaching that of the Murray—that would be impossible. The advantage of taking the water from the Snowy River would be to command the dividing range between the Murrumbidgee and the Lachlan Rivers.

Supply of water on the dividing ridge between the Lachlan and the Murrumbidgee.

1877. Do you mean to divert a portion of the Murrumbidgee water on the ridge? The Murrumbidgee does not produce water enough in snow-time to effect a very great improvement. A body of water like that in the Snowy River, laid on to the dividing range between the Lachlan and the Murrumbidgee, would have a wonderful effect on the country there; irrigation would be possible as far as the supply of water would admit.

1878. Put irrigation to some extent on one side—Do you consider that the advantage to be derived from diverting the stream for the supply of stations and farms would be very great? Certainly it would, but whether it would warrant the cost I cannot say.

Area of Snowy River to be diverted.

1879. Can you give the Commission any idea of the area of the Snowy River which could be diverted? About 165,000 acres altogether; 125,000 from the Snowy, and 45,000 from the Crackenback.

Levels useful to the Commission

1880. Can you give us the different heights in other parts of the Colony? We have a great many uncomputed heights in the triangulation, and a great many aneroid results, which can be put at the disposal of

of the Commission. I think though that the railway levels would, however, be more useful to the Commission. Mr. P. F. Adams. 16 Oct., 1884.

1881. But would not the levels which we can get from your Department give us information on a variety of points which we cannot get from the levels taken by the Railway Department? Yes.

1882. Have you any useful levels of the country between the ranges and the Darling? No; the trigonometrical survey has not gone over the range in any part. I think that the altitudes of all the meteorological stations are accurately determined by the Astronomer; they are accurate enough for your purposes. Altitude determined by the Astronomer.

1883. How were they taken? They are the result of a number of barometer readings.

1884. I suppose that you have seen the heads of most of the rivers? A great many of them.

1885. From your observations, do you think that any large quantity of water can be stored in natural basins by damming the rivers or by diverting them? No, I have no faith in that as a source of water supply. Storage in natural basins.

1886. Do you know whether towards New England there are any snow-capped ranges similar to those in the Snowy Mountains? No, the altitude is not sufficiently high for snow to remain long in the latitude of New England. Snow in New England.

1887. What further information can you give us with reference to the western side of the Kosciusko range? It appears to me that it is nearly possible to bring a supply of water from the Tooma on to the range between the Murrumbidgee and the Murray. Supply from the Tooma on to the range between the Murray and the Murrumbidgee.

1888. But in doing that, you would be simply robbing one river to divert the water to another? The object would be to distribute the water at a high level. To a certain extent the water which comes down the Murray goes to waste. 1,000,000 gallons distributed on top of the range would be more valuable in producing than 20,000,000 gallons going down the river.

1889. Do you know any name at that point by which we can distinguish it? It is above the junction of the Pound Creek with the Tooma River, below the mountain called Black Jack, or as it is named on the map, Manjar. Although I have no heights to prove it, I am quite as certain of the probability of it as I am of the possibility of diverting the water of the Snowy as I have suggested. It is weighted with the same physical objections as the other scheme, and through physical difficulties neither may be thoroughly practicable, still they are possible, but whether they are practicable or not I shall not say. Point of diversion above junction of Pound Creek with Tooma River.

1890. Is it your idea to throw the water across the ridge on to the Murrumbidgee Falls or the Murray Falls? I would keep upon the Murray Falls until a point on top of the Dividing Range is attained. The water to be kept upon the Murray Falls.

1891. When you reach that point, which way would you propose to throw the water? I could not say. It is immaterial. Once the water is on top of the range it is at command, and may be diverted in any direction which would be desirable or which would present the least physical difficulties.

1892. Do you know that part of the country well? Tolerably well, but I have not been there for about twenty years.

1893. Is the valley above the point you speak of, where the water can be diverted, what is known as Toolong Plains? I do not know what is the exact position of Toolong Plains. The object of my evidence is to point out the only localities which I know of that bear any comparison with the water-producing localities of India and California.

1894. Do you think that it would be possible to lay down pipes of sufficient size to divert such a quantity of water as would be of any value for distribution in the lower country? I could only refer to what has been done in other countries. Pipes for diversion of water.

1895. Have you any reports with reference to inverted siphons? No; I think that Mr. Darley is possessed of some valuable information on this subject. Inverted siphons.

1896. Have you any levels connected with the rivers of the Colony? I cannot indicate any, for when levels are taken in my Department it is generally for some purpose beyond it, and copies are not kept.

1897. *Mr. Gipps.*] For what purpose do you suggest that the Snowy River should be diverted into the Murrumbidgee? To supplement the Murrumbidgee supply, or to keep a constant supply in Lake George, or to irrigate the country between the Lachlan and the Murrumbidgee. Purpose of diversion from the Snowy into Murrumbidgee River.

1898. You consider it feasible to make a large and impounding reservoir of Lake George? I think so, but I should not like to say so positively because I have an idea there would be difficulty in getting the water out of it, but I have not investigated the matter. Lake George.

1899. Can you give us any information with respect to contour surveys of New Zealand? No, I have not seen any of their contour surveys Contour surveys.

1900. Do you think it would be feasible for surveyors here to take contour levels? Certainly. Contour levels.

1901. Do you think it advisable? The cost would be very great; in fact a contour survey would have to be made independently of the ordinary measurements for alienation—it would be far more economical to do so. In the course of the contour survey the position of alienated and mapped measurements could be picked up and connected with the contoured features already surveyed.

1902. Would not a contour survey give a better idea of the general features of the country? It would be very valuable, but it would be very costly.

1903. Do you know anything about the question of diverting a portion of the Murrumbidgee into the Yanko? I have been there, but I am not in a position to say more than that I think a dam in the Murrumbidgee a few feet high would turn a stream of water down the Yanko. Diversion from Murrumbidgee into Yanko.

1904. Do you think that the stream would be so great that it would practically affect the Murrumbidgee lower down? I do not.

1905. Have you had any levels taken in that part of the country which would be useful to the Commission? No. I know that the general inclination of the country there is westerly, and that it is from 8 inches to a foot in the mile. Incline of country.

1906. Do you think that the work which you have suggested ought to be carried out by the Government, or that Water Trusts should be appointed? It may not be possible to carry out such a work in our time. It is an enormous scheme I have not formed an opinion as to how it should be worked. How the suggested works should be carried out?

1907. But do you not think that it should be made a national work? I have never considered the question, but probably it should.

The

The Honorable William Adams Brodribb, M.L.C., called in and examined:—

The Hon. W. A. Brodribb, M.L.C.

16 Oct., 1884.

1908. *President.*] You have had considerable experience in the interior of the Colony I believe? Yes. I have put my views in writing, and with the permission of the Commission I will read my statement. I have been occupied in pastoral pursuits in various parts of this Colony since 1835, viz., Maneroo, Gundagai, and Goulburn, up to 1854. I then took up new country on the Billabong Creek, about 30 miles north of Deniliquin, where I formed the Wanganella Station, it being almost waterless when I purchased it, in a state of nature, from Mr. Alexander Innes. I first saw it in 1854, and then chained down the almost dry creek from the Conargo Waterhole to the Wanganella Waterhole, a distance of 20 miles, and then on to the Croonboon Waterhole, 12 miles further down. I was enabled to mark off my new purchase from what was called the Ten-mile Waterhole, down the creek, a distance of 12 miles. The run ran back 5 miles on each side of the creek, comprising an area of 120 square miles. On the 1st January, 1855, I formed an expedition overland, crossing the Australian Alps in the middle of summer with my stock. It took me three months to reach Wanganella. The country was very dry, as there had been no rain for nearly twelve months, and bush fires had extended for miles; nearly the whole of the run had been burnt, and there was little or no water in the creek, and the prospect for the future was most gloomy and depressing. After various troubles and losses, I had to turn my whole attention to the securing of water—first, by dams on this intermittent creek, which passed through very level country for nearly 200 miles to the Edward River. A few yards below the Wanganella Waterhole I commenced to construct an over-shot dam, by placing two rows of piles across the creek, in the shape of the creek. The upper row I lined with sheets of zinc, filled in with clay between the two rows of piles, and then covered the same with zinc; I made a kind of apron, of wood, below the lower row of piles, for the water to fall on, and above the upper row of piles I carted in a large quantity of clay, sloping up to the top of the dam. No water came down the creek for upwards of ten months after I had completed this dam, and we had only about 18 inches of water in the hole above the dam. I had to sell all my stock off except my horses; a neighbour of mine on the Edward River wrote and offered me a vacant place he had on the river and a paddock in which I could put my horses, and I was about to avail myself of his kind offer when I heard the creek had commenced to run some distance up near the ranges. However, it came down very slowly, as the creek was very dry and tortuous. At last it reached my dam; I watched it carefully until 2 o'clock in the morning, and saw the water flow in. To my great delight it showed no sign of leakage in the dam; it became quite a flood, and covered the whole dam. The structure was quite out of sight for nearly six weeks, and the surplus water flowed into the Edward River. When the water began to subside I placed sand-bags across the dam, and thus the water rose 2 feet higher, making the depth of water at the dam about 6 feet, and about 18 feet in the natural hole, and the water backed up the creek about 5 miles. I kept a gauge in the dam, and I looked at it every Sunday. I found that on an average the evaporation was about an inch a week. The stock used to go to the dam for water, and sometimes my neighbour's stock were watered at it. I subsequently made another dam of the same kind, about 8 miles higher up the creek, and thus secured a supply of water for a considerable time, as I thought. I re-stocked my station. Many squatters up the creek followed my example, and some came long distances to see my dams. Another dry season came on, and those who had not constructed dams to secure water suffered considerably. In some of the wells I sank the water was brackish, still, after a time, the sheep drank the water, and did very well on it. About the early part of 1858 a party of men went up the creek in the middle of the night and destroyed the Coree Dam, the property of Messrs. F. and G. Desailly, who repaired it, and for weeks kept armed men to prevent it being destroyed again. However, a party of twelve men went up the creek and destroyed about twenty-three dams, under the impression that their runs would be supplied with water. This destruction of property was perpetrated by men who had neglected to secure water by construction of dams when the creek flowed through to the Edward River for weeks, but they were doomed to disappointment, for, having cut the dams, they found the water did not run more than two or three miles below each dam. They came to my house on the 17th November, 1858, and told me they had burnt my upper dam by fire, there being no water in the dam at the time. They went to my house dam and cut away two panels, but there was very little water in the dam at the time. I prosecuted them before the Deniliquin Court of Petty Sessions, and three of them were committed to take their trial at the Goulburn Quarter Sessions to be holden on the 10th January, 1859. I had to go by Melbourne, thence by water to Sydney, and on by mail-coach to Goulburn, and, after all, the men were acquitted, and afterwards brought an action for damages against the Magistrates for committing them, and I had to attend at the Supreme Court in Sydney at a great deal of inconvenience. The case went on for sixteen days, when the men withdrew it, and they had to pay all costs. I repaired the dam after it was cut. This dam had been constructed twenty-eight years back, and has never been empty since, and has supplied the Wanganella township with water, besides having supplied the stations on each side with water. The destruction of dams occupied the attention of every one in the neighbourhood, so much so that the Government, through the Commissioner of Crown Lands, ordered the Commissioner of the district, Mr. Chas. G. N. Lockhart, to report upon the desirability of constructing dams along the Billabong Creek, and of suggesting some scheme which would be acceptable to all parties on the creek. The settlers along the Billabong Creek, seeing there was no protection to those who constructed dams, held a meeting, and they appointed a Committee to examine the upper part of the Yanko Creek, where a channel came from the Murrumbidgee River, opposite Narandera. A Company was formed to make a cutting in the Yanko Creek at such a depth as to allow the water in ordinary floods to flow down, first into the Colombo Creek, and then into the Billabong, and each settler was to contribute so much, according to the frontage on the creek. This undertaking cost between £10,000 and £12,000. I contributed £800 towards the work, and never received any benefit from it unless in very extreme floods, as the water below the Yanko Station, on the Yanko Creek, was absorbed in the bed of the creek. At Bundure a horse would even have to swim over when the creek was running a strong stream, but a mile or so lower down it would take a week or ten days to run two or three miles. About a foot under the bed of the creek was loose sand, which absorbed nearly all the water. I was once located on this creek, and in making a yard I tried to dig a post-hole in the bed of the creek; I came upon sand and water. This at once accounted for supply of water in the wells sunk out on the plains 100 miles in a western direction lower down. I subsequently formed stations north of Booligal about 30 miles, and when inspecting the country in 1863 we had to cart water from the Lachlan River for ourselves and horses, the whole country being quite waterless. We had to sink wells and make dams in some dry watercourses.

Effect of the drought in 1855.

Over-shot dam below the Wanganella Waterhole.

Evaporation 1 inch a week.

Quality of water.

Twenty-three dams destroyed by men.

The Wanganella dam never empty for twenty-eight years.

Yanko Creek.

Water absorbed in the bed of Yanko Creek.

Drought in 1863.

courses. These watercourses were supplied occasionally by local rains. The wells we sank varied from 120 to 140 feet deep, and the water generally rose from 20 to 40 feet in each well, but the water was slightly brackish, and the stock got to like it after a while. Near our head station was a dry cane-swamp. In a wet season I have seen the water running into this swamp for days, and disappearing down wide cracks in the swamp. At last the earth would fall in and these cracks become choked up, and then the water would remain on the surface. I remember on one occasion, in 1867, I was travelling with the Commissioner, Mr. Futter, when he was appraising runs. We were camped under the Wanarary mountains, some 50 miles north of our station, when it came on to rain in the night, and at daylight a volume of water came down in torrents through a gorge between the mountains. The creek was so rapid that a horse could not cross it with safety where we were camped. After breakfast I had the curiosity to walk down the creek, about half a mile into the level country, and to my astonishment all this water running for forty-eight hours went into the ground covering not more than 50 yards square. This at once accounted to me for where the water came from which supplied the wells on the level plains. I was then located about 5 miles south of the Willandra Creek. The occupants of this creek came to the determination of adopting the same plan that was resorted to some years previously in the Yanko Creek, near Narandera, and make a cutting, so as to allow the water from the Lachlan to flow down it. I have been told not one drop of water had flowed down this dry watercourse for upwards of twelve years. Mr. R. Kennedy, of Roto, Messrs. Whittingham Bros., and Messrs. F. C. and K. E. Brodribb, and the Messrs. Desailly completed this cutting at a cost of over £10,000, and they subsequently constructed dams for miles down this at 8 or 10 miles apart. In 1864 there was not a sheep on this creek—now there are upwards of 5,000,000. There are wells sunk out on the plains on each side of the creek. During heavy floods this creek flows through and fills all the dams. Each dam has a by-wash, to allow the water to flow back into the creek. In ordinary floods the water does not flow all down the creek. The settlers lower down threatened to go up in a body and cut the dams, and in some instances it was done, and this is the reason why I have been for the last twenty-five years trying to get a law passed to legalize the construction of dams on equitable and fair principles. I remember on one occasion being out some 30 miles north of the Mossgiel station, at a place called Ganoble. In front of the house there is a large dry lake, quite 6 miles across, and in crossing this dry swamp I have often wondered how and when it became filled. When filled it would hold a large body of water, covering quite 20 square miles of country, or 15,000 acres. On the last occasion I had to visit this part of the country it was just after a heavy flood in the Lachlan River, and the Willandra Creek ran all through, nearly if not quite 200 miles. To my surprise, I found the water running into the dry swamp at Ganoble. The shepherd told me the water had broken out of the ground on the eastern side of the lake, where there was no watercourse from the Willandra Creek, and ultimately the dry lake became full, and had the water continued running down the Willandra Creek it would have filled another dry swamp north of the Ganoble Swamp, as there was a dry channel between the two. I am quite convinced, from what I have seen during a long experience, that we are only on the threshold of discovering the best mode of supplying the dry pastoral country with water by wells and dams. I firmly believe this is far more important even than the Land Bill, for without water more than two-thirds of the Western Division is useless. As a rule, well-water is useless for irrigation. Our Land Laws since 1861 have rather tended to discourage enterprise. By judicious legislation, agricultural and pastoral pursuits might work in harmony with each other, but the present laws make them antagonistic, and unless properly administered the new law will be no better than the old one.

The Hon. W. A. Brodribb, M.L.C.

16 Oct., 1884.

Water coming down from Wanarary Mountain.

The Willandra supplied from the Lachlan.

Law to legalize the construction of dams.

Dry lake at Ganoble.

Water broken out of the ground.

Well-water useless for irrigation.

THURSDAY, 30 *OCTOBER*, 1884.

Present:—

MR. BARTON, M.P.,
MR. DONKIN, J.P.,
MR. FRANKLIN, C.E.,
MR. GIPPS, C.E.,
MR. LYNE, M.P.,
MR. MURRAY, M.P.,
MR. M'MORDIE, B.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. W. B. Henderson called in and examined:—

Mr. W. B. Henderson.

30 Oct., 1884.

1909. *President.*] What is your official designation? Superintendent of diamond drills.
1910. How long have you been in the Colony? Since September, 1872.
1911. How long have you occupied your present position? Since April, 1882.
1912. What was your occupation before that? I was connected with mining generally.
1913. In what parts of the Colony? I have had charge of mines all over the Colony; in fact I was engaged by a Sydney firm to travel over the Colony and inspect mines on their behalf.
1914. In what parts of the Colony have you worked the diamond drill? Chiefly in the eastern coast district and the central parts of the Colony.
1915. Have you had anything to do with the drills working west of the Darling? Yes, with auger drills.
1916. Can you give us any information respecting bores put down on the western side of the Darling? I have sections of the bores put down between Bourke and Wanaaring. Here is a section of a bore put down 51 miles west of Bourke. (*Appendix* L 1.)

Sections of bores between Bourke and Wanaaring.

1917. Fresh water was struck in the bore at a depth of 30 feet? Yes.
1918. To what height did it rise in the bore? The lower we struck water in the bore the higher it rose. At 61 feet we struck fresh water again, and it rose to within 3 feet of the surface. At 70 feet we struck fresh water again, and it rose to the same level. At 89 feet 2 inches we struck fresh water, which rose 8 feet above the surface, giving 1,000 gallons per day.

Rise of water in the bore.

1919. Were there any indications of water on the surface before you put the bore down? The Goonery Springs are not far distant.

Goonery Springs.

1920. What kind of springs are they? Mud springs; but they were not giving out much water when we started the bore.
1921. What is the distance between the springs and the bore? It might be a quarter of a mile; there are several springs.

Mr. W. B. Henderson. 30 Oct., 1884.

1922. Have you had the water from the bore and from the springs analyzed and compared? No; but I have had the water from the bore analyzed.

Rise of water in tubed bores.

1923. *Mr. Barton.*] Have you ever found, when you have struck water and it has risen to a certain height, that by putting tubes in the bore the water has risen higher? The bore to which I am referring had to be tubed. The most important consideration in connection with our work when water is struck is to ascertain the quantity and quality of it; sometimes boring is discontinued for days for this purpose. After the water has risen to apparently its highest level, we pump it out to see if it will rise to the same level again in equal quantity, and, periodically (every six months, as near as possible), the supply coming to the surface is tested. When we have tested the supply of water at any depth, and it is decided to continue the bore, the water is shut off, so that the supplies from different depths are not mixed. You will see from sections which I have brought with me that we get fresh and salt water near together, but we prevent them from becoming mixed. The ground would not stand unless the bores were firmly tubed. We are using Wright and Edwards' Australian water auger, to work which the bore must be dry.

Test of the supply.

Preventing salt water from mixing with fresh water.

Fresh water in cretaceous formation.

1924. *President.*] The first three supplies of fresh water in the bore to which you have referred were struck in sandy drift, and the last supply in blue clay and flinty sandstone? It is all cretaceous formation.

Bore 7 miles west of Goonery Springs.

I have brought with me specimen cores from a bore which we had put down about 7 miles west of the Goonery Springs. This one is down 470 feet, and there is an artesian supply of water. (*Appendix* L 2.)

The formation dips to the west.

1925. These two bores show that the cretaceous formation dips to the west? Yes, very fast. The water is obtained in the two bores in the same kind of strata. The formation is the same, only that in the western bore is covered by another formation which does not exist in the locality of the Goonery Springs bore. There is a large supply of salt water over the fresh water. The water flowed over the surface from both bores, the depth of one being 89 feet 2 inches, and the other 474 feet.

Lap-welded artesian tubes.

1926. What kind of tubing do you use? Lap-welded artesian tubes, with specially made joints.

1927. Will that kind of tubing last? Yes, it is the best quality of tubing.

Size of bores.

1928. What is the size of the bores which you put down? We start at 8 inches, and then we put in 7-inch tubes, and so on as occasions require. The tubing is done on the telescopic principle. We put down a 7-inch tube as far as it is possible to force it, and then the size of the bore is reduced. This system is absolutely necessary when passing through country which is composed of swelling clay. It is possible on this principle to bore to a depth of 3,000 feet, the size of the tubing varying from 7 inches to $2\frac{3}{4}$ inches. As a rule three or four changes in the size of the tubing are sufficient.

Map showing position of bores.

1929. *Mr. Murray.*] Have you a map showing the positions of bores and wells throughout the country? Yes, I produce a map (*Appendix* L 3), accompanying which there is a tabulated statement giving all the information which I have been able to gather respecting bores and wells.

Artesian water west of Bourke.

1930. *President.*] In the bore at the 57-mile post, west of Bourke, at what depth did you strike artesian water? It was artesian from 349 feet, at which depth brackish water was struck.

Dip of the cretaceous formation.

1931. You say that the difference in the depth at which the cretaceous formation was struck in the bores shows that the formation dips very much to the west? Yes, I should think that between the two bores it dips at least 400 feet, or about 60 feet per mile.

1932. If that theory be correct, there must be an immense cretaceous basin to the north and west? My idea is that the fast dip indicates that the bed cannot extend over a very large area; if the dip was less it would indicate that the bed extended over a larger area.

Cause of presence of salt water.

1933. How do you account for the presence of salt water there? It arises from the saline properties of the deposits which were made when the land was under the sea. There have been deposits at different times, and in some of the beds, which are almost horizontal, we get salt water and in others fresh water.

Supply from the 57-mile post bore.

1934. Can you state the supply of water from the bore at the 57-mile post? It has been tested from week to week, and the supply appears to be getting larger. The present supply is 4,320 gallons per day. I produce specimens of the core from this bore. The fossil shell embedded in the rock came from a depth of 461 feet. The water coming from the bore is quite fresh. I wish to direct particular attention to the fact that this bore, the bottom of which is through hard rock, was put down by Wright & Edwards' steel borer.

Size of tube at surface.

1935. What is the size of the tube at the surface? 6 inches.

Size at lowest depth.

1936. And at the lowest depth? 4 inches. When the ground becomes as hard as it is in the bottom of the bore nothing but a diamond drill will work through it to advantage.

Duration of work.

1937. How long have you been working at that bore? The work was started on January 28th last, but only one-third of the time has been occupied in boring, owing to the very dry season.

Number of men employed.

1938. What number of men have you had working there? Three, generally engaged boring, together with teamster and cook.

Weight of boring apparatus.

1939. *Mr. Gipps.*] What is the weight of the boring apparatus? 3 tons 10 cwt. complete.

1940. Does that include all the necessary tools? Yes, the top portion of the apparatus is very light; the principal weight is in the rods.

Cost of the bore.

1941. *President.*] Can you give us an idea of the cost of the bore at the 57-mile post? Yes, I can furnish it (*Appendix* L 4); but I wish to explain that before we struck water there we had to cart water from Goonery, and had occasionally to use manual instead of horse-power to work the borer.

Depth of alluvium.

1942. *Mr. Gipps.*] What was the depth of the alluvium? About 30 feet, I think.

1943. Did you get any water in that? Salt water.

Cost of work reduced to a minimum.

1944. *Mr. Franklin.*] I suppose that you carry on your operations in such a way as to reduce the cost to a minimum? Yes; I am prepared to show that we are boring at less than half the cost of similar work in other Colonies.

Work retarded through the tests.

1945. Do not you think that the work is retarded very much by the tests which you make as to the quality and quantity of the water? Yes; but I regard it as being of far more importance to ascertain what is the extent and quality of any supply of water which may be struck than to have a bare record of having bored so many feet. Sometimes the men are knocked off from boring work for a week while we are making these tests, and consequently the cost of boring is very much enhanced. Of course if these tests were not made the bores would be put down much quicker than they are—in some cases probably in half the time. I wish to lay before the Commission a report which I have prepared (*Appendix* L 5) as to the merits of the different boring machines which I have tried.

Cost increased by the tests.

1946. Would it not be possible to deduct from the total cost of each bore the cost which has been rendered necessary by the tests which you have made? Yes, I can produce a tabulated statement showing exactly how the time of the men has been occupied. (*Appendix* L 6.)

1947.

Mr. W. B. Henderson.

30 Oct., 1884.

1947. Would such information be available to-morrow, so as to be attached to your evidence as an appendix? It will take some time to work it out. I have tabulated all the work done by diamond drills last year, but I have not yet made out a statement of the work done by the water-boring machines.

Average cost of the whole of the bores.

1948. *President.*] Taking the whole of the bores, can you state approximately the average cost of the work? The cost of the labour is about 16s. 5d. per foot up to date for bores for water for public purposes. Taking the bores put down for private individuals the cost of labour is 15s. 5½d. per foot.

1949. Can you state the cost, including the carriage of material and other expenses? £1 12s. 11d. per foot. The carriage, it must be noted in these cases, is very heavy. I wish to put before the Commission a statement showing the quantity of water pumped from certain mines in the Ballarat Districts. (*Appendix* L 7.) I think that this statement is important, as showing that as there are such large quantities of water on the dividing range, much larger quantities may be expected to be found in the lower country further west. I also wish to put before the Commission an important letter which I have received respecting boring machines. (*Appendix* L 8.) In that letter it is stated that the cost of boring 1,330 feet for the South Pacific Petroleum Company in New Zealand was for labour £4,430, or £3 6s. 8d. a foot, and that the plant and tubing cost £6,650, or altogether over £11,000.

Large quantities of water in the lower country west.

1950. *Mr. Gipps.*] What machine was used? The Pennsylvania Oil-boring Machine.

Pennsylvania Oil-boring Machine.

1951. Is that similar to the "Tiffin"? It is more massive, and it is supposed to be capable of boring deeper than the "Tiffin."

1952. *President.*] Does not the engineer who put down the bore state that the cost would not have been nearly as much if a diamond drill had been used? Yes.

1953. *Mr. Gipps.*] Who superintended the working of the drill? A man who came from America with this Pennsylvania Oil-boring Machine, and who was paid £30 a month.

Wells between the Narran and the Barwon.

1954. *President.*] What do the circles on the map between the Narran and the Barwon represent? Wells; but we are putting down bores there.

1955. Can you give us any information about them? I have every belief that we shall get artesian water there, but we are not yet deep enough. The greatest depth of any of the bores is 153 feet.

1956. Is the country similar to that west of the Darling? No, it is quite different.

Bores on a branch of the Namoi.

1957. Is it not cretaceous? I think not; there is a lot of gravel there. I am also putting bores down on a branch of the Namoi; there are two bores down 280 feet there.

1958. Are they close together? No, they are some distance apart, but on the same station.

1959. Have you struck water? Yes, we have struck fresh water at 174 feet, which rose to within 80 feet of the surface, and again at 215 feet 10 inches, which rose to within 78 feet of the surface. Neither supplies are, however, artesian.

1960. In any quantity? 7,360 gallons per day from one bore.

Pressure of gravel drifts bursting the tubes.

Old river beds.

1961. What is the nature of the country which you are passing through? Immense gravel drifts, the pressure from which sometimes bursts up the tubes and fills the bore for 80 feet. The bore is in Mr. Capel's station, and he describes the strata which the bore tapped as being that of an old river bed.

1962. How far is it from any existing river bed? It is about 25 miles from the Namoi, and about 40 miles from Walgett.

1963. Is there no river bed nearer than that? I believe there are some small creek courses.

1964. Have you ever had anything to do with wells? I have obtained a large amount of information respecting them, which is contained in the document which I have already submitted. (*Appendix* L 3.)

1965. Do you know anything about the wells shown on the map on the Darling, near Walgett? They are private wells.

Wells west of the Darling.

1966. Have any wells been sunk by the Department west of the Darling? No; but I have obtained information respecting a number of wells in that part of the country, which information is contained in the paper to which I have just referred. I forgot to mention just now that I have three boring parties at work between Wilcannia and Silverton, but as the work has just been started no results have been obtained beyond the striking of salt water at 80 feet in one bore. The only part of the Colony respecting which I have not given information as to wells and bores is Riverina and the extreme north-west.

Bores near Narrabri.

1967. Have you any bores in the eastern part of the Colony? We have some bores near Narrabri in which the salt and fresh water are mixed; but I hope to succeed in getting fresh water, as the formation is similar to that between the Barwon and the Narran. I have been informed that from a bore put down on Mr. Bignall's Widgeegoara Station, in Queensland, made by a diamond drill to a depth of 250 feet, the water rises to a height of 40 feet under the surface. The force of water was so great that weights had to be put upon the tubes to keep them down.

Bore on Widgeegoara Station (Q.)

Section of bore on the Weelamurra Station.

1968. What was the size of the bore? I think it was about 3 inches where the water was struck. I wish to produce a section of a bore put down on the Weelamurra Station, in the Warrego District, by Mr. King, the owner of the station. (*Appendix* L 9.) First of all he started a shaft, but abandoned it at 30 feet or so, and from the bottom of the shaft started a 3-inch bore. At 38 feet from the surface fresh water was struck, the supply being equal to 1,000 gallons a day. At 60 feet salt water was struck, and this rose to 38 feet from the surface, the supply being about 1,000 gallons a day. At 230 feet fresh water was again struck, and this rose to 38 feet from the surface, the supply being about 1,000 gallons a day. At 300 feet brackish water was struck, which rose to 38 feet from the surface, the supply being 1,000 gallons a day. At 320 feet fresh water was again struck. This also rose to 38 feet from the surface, the supply being about 750 gallons a day.

Artesian water.

1969. Do you not think it would be advisable to start the tube from the surface, so as to ascertain whether the water is artesian or not? The chances are that unless the tube is very deep the water will not rise to the surface. I imagine, from the fact that all the water struck has risen to the same level, that there must be a fissure or fault in the rocks there through which it escapes. I have known instances where water has been pumped by steam-power into the tube, and not risen above a certain level.

1970. *Mr. Franklin.*] The Boring Department has been in existence for two years? Yes.

1971. And all its operations have been recorded? Yes.

Expenditure on each bore.

1972. So that the actual expenditure on each bore would be known? Yes; the most minute information can be obtained from the Department, as I have furnished returns giving particulars of the work from day to day. We did very little work in 1883, and we have not properly started yet. I did not believe in rushing the Department into heavy expenditure until I had tested the various boring machines. I have found many machines perfectly useless. I can at the present time buy American-made machines, which

are

Mr. W. B. Henderson. 30 Oct., 1884.

are supposed to be good ones. at the price of old iron. I refer to this subject more particularly in a report which I have submitted, and I have not condemned any machine without first giving it a fair trial. I have worked the "Tiffin" and the Wright and Edwards' machines together; they have been worked under the charge of one man, and at the same place, and I have kept a return showing the number of hours which they have worked and the cost of the work performed by each. It is almost heartrending to observe the great waste of money which is incurred by the use of some of these imported boring machines. Take the case of the New Zealand Company. The work done in that case ought to have been done three times over at the cost stated.

Trial of various machines.

1973. *President.*] Mr. Darley, in the evidence which he gave to us, mentioned an instance where, in America, an 8-inch bore has been put down 500 feet and tubed in 11¼ days at a cost of 6s. 8d. per foot? It is not difficult to bore at that rate; it all depends on the nature of the strata. I have put down 100 feet in 26 hours with an Australian-made machine, and in differing strata it might take 6 weeks to pierce as many inches. The difficulty which we have to contend against here is the swelling clay. You may bore a hole to-day and find it filled up again in the morning, and have to re-bore it.

Australian-made machine.

1974. *Mr. Donkin.*] Do you know anything about the Pierce borer? Yes; I know that under Captain Matthews' supervision one was used at Temora. It worked very well until he got down to the reef rock; it was of no use after that. The last time I saw it, it was lying at Temora out of use. The machine is one which is thought highly of in America. The Pennsylvania oil-borer would be successful when boring in Sydney sandstone or shales, but it is not suitable for swelling clays and drifts.

SATURDAY, 15 NOVEMBER, 1884.

At Narrandera.

Present:—

Mr. BARTON, M.P.,	Mr. GIPPS, C.E.,
Mr. DONKIN, J.P.,	Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E.,	Mr. MURRAY, M.P.,

Mr. M'MORDIE, B.E.

W. J. LYNE, Esq., M.P., President, in the Chair.

Mr. James Cochran, grazier, called in and examined:—

Mr. J. Cochran. 15 Nov., 1884.

1975. *President.*] Where do you reside? At Widgiewa, on Colombo Creek.

1976. The Colombo is an off-shoot of the Yanko? An ana-branch of it.

1977. And part of the water which would run from the Murrumbidgee into the Yanko would flow into the Colombo? Yes.

1978. For how many years have you known the Yanko and Colombo Creeks? Twenty-five.

1979. Did you reside in the locality before the Yanko cutting was made? Something, but not very much, had been done to it before I went there.

Murrumbidgee waters running down the Yanko.

1980. Can you give us any idea as to how often the waters of the Murrumbidgee used to run down to the Yanko before the last cutting was made, taking a series of years? It used to run down a slight distance whenever there was a great flood; but unless there was a flood the water never ran down.

1981. How often has the water run down the cutting? It has run a slight distance down every year since I have been there.

1982. As far as Widgiewa? No.

1983. Have you any records showing how often the water has run down to the Yanko since and before the present cutting was made? No; but I think that it has run down much oftener since the present cutting was made.

1984. Taking a series of years, how often has the water run sufficiently far to be available to any number of people? It has been available to people a short distance down, but not to those below.

How far the water runs down.

1985. How far does the water generally run down? For several years it has not run further than Goree Station on the Yanko. I have known it to get as far as Bundure, which is the next station, but for the last five years it has not reached the next station—the Yanko.

Height of Murrumbidgee to permit the water to run down Yanko Creek

1986. How high has the Murrumbidgee to be above summer-level before the water will run down any distance? We need not expect any great quantity of water to flow down the Yanko unless the river is at least 10 feet above summer-level.

Dams on the Yanko.

1987. Are there many dams on the Yanko? There are none for a great distance. The first of any size is at Bundure Station; there was one at Goree Station, but it was cut away.

1988. Does the dam at Yanko Station prevent the water from flowing lower down? Oh no; all the dams that I know of have proper off-shoots to turn the water into the main channel after the dams are full.

1989. Are there many dams on Colombo Creek? Yes.

Effect of dams on Colombo Creek.

1990. What effect have they on the water lower down the creek? The Colombo Creek would not hold water at all if it were not for the dams; there are no natural water-holes in it. When one dam gets full the water passes over the by-wash into the creek and fills the next dam, and so on; and by these means the supply is retained.

The selectors' need of water.

1991. Are there many selectors on the Yanko and Colombo Creeks? There are a great many on both of them, but more on the Yanko than on the Colombo.

1992. How are they off for water at the present time? A great many of them are badly off.

1993. Have they made provision themselves by constructing dams in the creek, or have they made dams off the creek? Some of them have tanks off the creek, but I don't know that any of them have dams.

1994. Then they are dependent on the creek water for their supply? I think so.

No water runs down the Yanko in summer.

1995. Do you often get the water from the Murrumbidgee into the Yanko in December, January, or February? It is never known to come down as late as those months. I remember one occasion though when the water came down in December from a great snow-flood.

1996. But there are not often snow-floods in the Murrumbidgee? No.

Mr. J. Cochran.

15 Nov., 1884.

1997. Have you any idea as to why there is so little snow water in the Murrumbidgee compared with that in the Murray? I am not sufficiently acquainted with the country at the head of the rivers to give an answer to that question.

Supply of water in the Yanko.

1998. Does it appear to you that if the proposed cutting from the Murrumbidgee to the Yanko is made in any reasonable way so as not to interfere with the interests of persons down the river, the people along the Yanko would be well supplied with water? I think so; I think that the scheme is a feasible one.

Amount of supply wanted.

1999. Speaking as a representative man on those creeks, can you say whether it is the desire of the people on the Yanko to divert any large quantity of water? Not more than will keep a supply from year to year. We do not wish to use the water for irrigation purposes—we merely want a supply for stock.

2000. Suppose a supply were provided at certain times during each year to enable people to fill their dams and tanks, would that be satisfactory to them? Speaking for myself, I may say that that is all I want.

Irrigation on the banks of the creeks.

2001. Is there any large amount of irrigation carried on on the banks of the creeks? Not that I am aware of.

2002. Do you yourself irrigate? I have a dam in the creek from which I raise water for my garden, but that is done on a very small scale.

System of dams.

2003. In placing dams on the creeks would you recommend large dams or over-shot dams? Over-shot dams would not be suitable for the creeks, as they would not retain a sufficient supply of water.

Tanks useless through evaporation and soakage.

2004. Would there not be a sufficient supply of water if tanks were excavated above the dams? No, the soakage and evaporation are so great that any supply which would be kept by such dams would be totally inadequate. I have known water to soak away and evaporate from a dam in the Colombo Creek to the extent of from 8 to 10 feet in the course of a summer; that is, the depth would be reduced from 15 or 16 feet to 8 feet.

2005. But were not the stock watered from the dam? Yes, but the proportion of water consumed by the stock was very small in comparison with that which soaked away and evaporated. Probably not more than from 3,000 to 4,000 sheep were watered at the dam.

Necessary height of Murrumbidgee to secure sufficient supply.

2006. At what height of the Murrumbidgee should water be allowed to run down the Yanko to be of any service to the people on the creek? I do not think it would be of any use at less than 10 feet above the summer level.

2007. Do you think the water ought to be tapped at, above, or below summer level? I think summer level would be sufficient.

Locks.

2008. Do you think the water ought to be allowed to run down the cutting by gravitation, or that there ought to be locks in the shape of sluices? I think that an open drain would be quite sufficient. I do not think that any sluices will be needed if the work is carried out on the scale proposed.

2009. Would you propose to take the water at all times when the river was a certain height? Yes.

Nature of soil along creeks.

2010. What is the nature of the soil along the creeks? In some places the creeks run through sand-hills, in which the water soaks away to a certain extent, and in other places the beds of the creeks are composed of hard cement.

2011. What is the nature of the soil where the tanks and dams have been made? It is of a spongy nature—black loose soil.

Loss of stock

2012. Have there been any great losses of stock in that country, owing to the want of water? Yes.

2013. Do you think that such loss would be obviated to a great extent if the water were diverted as proposed? I am certain of it; great losses are occurring even now.

Soakage.

2014. *Mr. Barton.*] Can you give us any idea as to the amount of soakage which takes place when the creeks are running at full-flood or at half-flood? I cannot say. Of course a certain amount of soakage takes place when the river runs over the dry beds.

Velocity of water.

2015. When there is a full head of water running into the Yanko cutting, have you any idea as to the rate at which the water travels down? It depends on the height of the water at the back. I have known it to come down rapidly, but when the bed of the creek is dry, the first water does not come down at more than from 1 to 2 miles a day.

Length of the Yanko.

2016. What is the length of the Yanko Creek, taking all its bends? I should think about 300 miles.

Shortening by straight cuts.

2017. From your knowledge of the country, do you think it would be possible to shorten the distance by making straight cuts? That might be done, but I do not think it would be advisable; I think it would be better to follow the old channel.

Lowest level of Murrumbidgee.

2018. Have you known any year in which there has not been a considerable rise in the Murrumbidgee? This is the first season in which I have known the Murrumbidgee to keep as low as it has been.

2019. Has the river never been higher this season than it is now? I do not know what the height is now, but according to the gauge at Wagga Wagga, the height has not been more than 8 feet above summer level this season.

Taking the water at a low level.

2020. What advantage would be gained by taking the water at a low level, if, as you say, the river has never been known not to be flooded during the course of a year? In making a cutting in the way proposed, the width of it will always ensure us a small supply of water, which we do not get now when the river is low.

Lessening the loss from soakage.

2021. *President.*] If the bed of the cutting were kept constantly soaked, the loss of water by soakage would be very much less than it is now? Yes.

When the water is most required.

2022. Is it not when the river keeps low for a length of time, as it has done this season, that you require the water more particularly? Yes; we do not require it so much in seasons when the river rises several times.

Lake Urana.

2023. *Mr. Franklin.*] How far is Lake Urana from your run? In a straight line, about 20 miles.

2024. Does the water flow freely from Yanko Creek into Urana Swamp in flood-time? The swamp has no connection with the Yanko Creek; it is fed from the Urana Creek, which rises in the mountains, and from Coonong Creek, which rises in the plains.

2025. Is the water shallow in Urana Creek? Yes.

Dams on Urana Creek.

2026. Then it would not be possible to utilize it for storage purposes? There are some dams upon it which keep a supply of water for the season.

Urana Swamp as storage reservoir.

2027. Could Urana Swamp be utilized for the storage of any large quantity of water? I have seen a large sheet of water there which came from the overflow from the Murray.

2028. Do you think that if the water which goes into the swamp were diverted it would be of any use to the people there? I do not think it would be of the slightest use to the Yanko or Colombo country.

Mr. J. Cochran. 15 Nov., 1884.

The Billabong Creek.

2029. What is the area of the Billabong country, from its entrance to the Murrumbidgee to its outlet? The Billabong is not fed directly from the Murrumbidgee—it has an independent head of its own. The return water from the Colombo Creek goes into the Billabong at a certain distance down, but the Billabong has a stream independently of that. Of late years, however, the principal source of supply in the Billabong has been from the Murrumbidgee, through the Yanko and Colombo Creeks.

The area of the Yanko Cutting.

2030. There being such a long distance as 300 miles over which to convey the waste water of the Murrumbidgee, the area of the present Yanko cutting is not sufficiently large? Not at all.

2031. I suppose that if there was simply a passing flood in the river, you would not get any benefit from it at your station? No; the water from the Murrumbidgee has not run down to the Yanko Station for the last five years, notwithstanding that the river has been at least five times above summer-level.

Cutting silted up.

2032. *President*] The cutting has silted up very much since it was made? Yes, several new bars have formed, from stuff silting up, and drift-wood collecting, and the station-holders have periodically sent out men at their own expense to remove those bars.

2033. What was the cause of that? I think that the earth which was removed from the cutting was placed too near the edge of the bank.

2034. Was the cutting more serviceable before it was silted up than it is now? Yes; every new bar which forms stops a certain quantity of water from coming down.

th of water Urana Lake.

2035. *Mr. Donkin.*] What is the greatest depth of water in Urana Lake? I think about 10 feet.

2036. Has the lake any natural outlet? Two creeks run into it, but I do not think that it has any natural outlet.

Cockateegung Creek.

2037. Does not the Cockateegung Creek run from the Urana Lake into the Billabong? It might do so in time of great flood, but I have never known it to do so. My idea is that the water would have to be raised by artificial means before it would run into Cockateegung Creek.

Water going down the Yanko and the Colombo

2038. In flood-time what is the discharge of water from the Yanko into the Billabong? Three-fourths of the water goes down the Yanko, and one-fourth down the Colombo.

2039. Is there any connection between Colombo Creek and Yanko by Turn-back Jemmy Creek? I am not aware of any such connection.

Time necessary for the water to reach junction of Yanko with Colombo.

2040. Supposing there were a 10-feet flood in the Murrumbidgee, how long would it have to run before the water would go through the cutting to the junction of the Colombo and Billabong Creeks? I should think from six weeks to two months.

Benefit from proposed cutting.

2041. *Mr. Gipps.*] How many people would be benefited by making the proposed cutting in the Yanko Creek? There are a large number of residents on both creeks, but I cannot say exactly what the number is. There are several townships and small settlements along the creeks.

2042. Have not all the people made provision for water supply by constructing dams? Nearly all the station-holders have dams, but the selectors have not. They have tanks in the back country, but they get the benefit of the station-holders' dams.

Effect of cutting on tanks.

2043. Would a cutting fill those tanks? No, they have been constructed in the back country to catch the surface water.

Capacity of dams on Yanko Creek.

2044. What is the capacity of the dams in the Yanko? It is only the bed of the creek that holds water, and the dams are long, deep, and narrow. They have all been constructed with proper by-washes.

Fall of creek.

2045. What is the fall of the creek per mile? Not much more than two or three inches.

Under-current.

2046. Is there any under-current? There may be in the sandy bed of the Yanko, but I do not think there is any in the Colombo.

2047. *Mr. M'Mordie.*] You say that the water has been about 8 feet above summer level this year? Yes.

2048. If the dams had been filled at that time, would there have been a sufficient supply in them now? Yes, but none of them were filled—the water did not run down as far as the dams.

2049. All that you require is a cutting that would fill the dams when the river rises about 8 feet? Yes.

2050. Would not a constant supply of water at a low level be advantageous to the selectors who have not dams? Yes.

The payment of a rate.

2051. *Mr. Murray.*] Do you think that the people who would be supplied with water by means of the proposed cutting would willingly submit to a rate to pay the interest on the cost of the work? I think they would be quite willing to do so—I know that I should be. The matter is urgent, and this is the proper time to commence the work.

2052. *President.*] As legislation would be necessary before Water Trusts could be formed, would the people along the creek be prepared to pay a portion of the cost of the work and guarantee interest on the remainder, supposing the work were carried out by the Government? A proposal of that kind was made some time ago, but it never assumed tangible shape. If the carrying out of the work hinged on that I have no doubt the money would be found by the residents on the creeks.

Mr. George Mair, grazier, called in and examined:—

Mr. G. Mair. 15 Nov., 1884.

2053. *President.*] Where do you reside? At Groongal Station, on the Murrumbidgee.

2054. You have had considerable experience in irrigation works and works for the conservation of water? I have had a good deal of experience.

Experience in irrigation.

2055. Where? Chiefly on the Darling.

2056. Did your experience extend over many years? I had charge of one property on the Darling for eight years.

Conservation and distribution of water on the Darling Tallywalka Creek.

2057. From your knowledge of that river, do you think it possible to adopt any scheme for the conservation and distribution of water? There are a great many outflows from the Darling which, by means of cuttings or locks in the river, might be made to distribute an enormous quantity of water over the back country. There is a creek called the Tallywalka an ana-branch of the Darling, from which another creek flows, which is called the Terryaweynya Creek, which spreads into a number of lakes. Some of the station-holders there put a dam across the Tallywalka Creek, at a cost of £3,000 or £4,000, and the effect of that dam was to throw the water into a series of lakes extending north and south, a distance of 80 miles, and I should think giving several hundred miles of almost permanent water frontage.

2058. Do you think a scheme of that kind could be adopted in other places? There are many similar places on the Darling. There are a number of lakes filled from the Darling, some by creeks which do not run a long course, but into which cuttings have been made to keep them full. As far as I can judge, not being

Mr. G. Mair.

15 Nov., 1884.

being an engineer, I think it possible that works of this description might be carried out to a very large extent there—much more so than on the Murrumbidgee.

Diversion of water by cuttings without weirs.

2059. To raise the water it would be necessary to erect weirs across the Darling, below the outflows? That is a question upon which I should speak with some diffidence, because I do not know the levels. I took some levels connecting the Tallywalka with the Darling, and in some places I ascertained that by making comparatively inexpensive cuttings water might be diverted into that creek when the river rose, without the necessity for weirs.

Banks of the Darling.

2060. Are not the banks of the Darling nearer the river higher than the country beyond as a rule? Not as rule. The Darling is like all our other rivers,—in places there is a high bank on one side and on the other side is low land, a large area of which is flooded at times.

Construction of locks to allow navigation.

2061. If weirs were erected across the Darling and locks constructed to allow steamers to pass, do you not think it would be a benefit to the navigation? Unquestionably.

2062. And at the same time a large quantity of water could be diverted into the dry country? Yes, provided the weirs were a sufficient height.

2063. Have you had any experience of irrigation on the Darling? No, but I have had experience of it to a small extent on the Murrumbidgee.

Irrigation.

2064. Do you think that irrigation could be carried on to any extent on the Darling? I should not like to express an opinion on that point. I have had irrigation carried on at my homestead on the Murrumbidgee during the last four or five years, but not on any extensive scale. I raise water by means of pumps.

Expense of preparing land for irrigation.

2065. Do you find that there is much expense in preparing the land for irrigation? I have not carried on the work in a scientific way at all, but have merely thrown the water over the land. I find that by irrigating in a rough way I have been able to get crops of hay, wheat and oats, by way of experiment, and I have produced small patches of maize and English grasses; but I have not made any calculations as to the cost, and I should not like to offer any opinion as to the profitableness or otherwise of the work.

Effect of irrigation.

2066. I suppose that the difference between irrigation and non-irrigation is that in one case you are sure of getting a crop and in the other you are not? Yes, without irrigation we cannot be sure of getting crops, unless we have an exceptionally good season. I have a fairly good crop on 40 acres of land which I have irrigated this year. Seed was sown at the same time on land which was not irrigated, and there was no crop at all on it.

Number of immersions per year.

2067. How many times in the year do you irrigate the land? I flood the land three times while the crop is growing.

Stand of Murrumbidgee, near Groongal.

2068. Has the Murumbidgee been very low near Groongal this year? In the early part of the year it was exceedingly low. It usually reaches the lowest level about March.

2069. Do you know anything about the cuttings into the Yanko? No.

Effect of diversion into the Yanko on the water in the Murrumbidgee.

2070. From what you have heard about the proposal to deepen the Yanko cutting, do you think that the river water would be much affected lower down if a small portion of it were diverted into the Yanko at certain seasons? People below would not be affected unless the water were taken at a time when the river was at its lowest. Water might well be spared when the river was as high as it is at present. If any considerable extent of water were taken from the river when it was at a lower level than it is at present, it would occasion great inconvenience to the people below, particularly about Hay, Balranald, and in the back country there. It is a matter of life and death to people to have the river navigable. As long as the navigation of the river was not interfered with, property-holders below would not be materially injured. I do not think it would matter how wide the cutting was made, as long as it was not made too deep.

2071. Setting navigation aside, do you think that the diversion of the water as proposed would have any appreciable effect on the flow of the river? If the water were taken off in a wide cutting at a summer level unquestionably it would.

Determination of summer level.

2072. When the river is down to what is termed summer level, what is about the depth of water that flows over its bed? The summer level is an arbitrary term—there seems to be no rule by which to determine it. I have seen the river so low that in the deepest part it has not been more than 18 inches—the water would not come up to the horse's knees.

Hard clay bars.

2073. What is the nature of the bed at that spot? In places where the river is shallow there is usually a hard clay bar. I have frequently seen the river with not more than 18 inches of water in it at the deepest part.

Velocity of water.

2074. Was the water running rapidly? No, at about from 2 to 3 miles an hour.

2075. I suppose you have often seen the river in flood? Yes.

Ordinary floods.

2076. What area of land would be covered by flood between Groongal and Hay? The river scarcely rises beyond its natural banks in ordinary floods.

Area of flooded country.

2077. But suppose the river overflows its banks, what area of country would be overflowed by its waters? I should think there would be an average width of about half a mile, that is on one side.

Rapidity of rise of floods.

2078. Does the river rise rapidly at flood-times? When there are heavy floods it rises rapidly. In 1870 it rose from 15 to 16 feet in one night, but that was an exceptional case.

General system of irrigation.

2079. Do you think that any general system of irrigation could be carried on from the river? I do not think there would be sufficient water in the river for irrigation purposes when the water would be most required. Although I have been irrigating on a comparatively small scale, I should be quite prepared to have exception taken to my operations if I irrigated when the river was low. If half a dozen people would do as I do, the people below would certainly have a right to complain. With the river at its present height, irrigation operations have no appreciable effect on the volume of the river; but when the river was very low, a few large steam pumps would draw nearly all the water out of it.

Natural depressions of ground near the Murrumbidgee.

2080. Do you know of any natural points on the Murrumbidgee where the water might be diverted into depressions, and thus form lakes? I do not. There are some lakes near Balranald, but there are no ana-branches of any importance in this part of the country, and no depressions into which water might be diverted. This remark applies particularly to the northern side of the river. On the south side there is a creek called the Gum Creek, which is an ana-branch of the river, flowing out of it about Kerarbery, and again flows into the river about Burrabogie. This creek has branches extending in various directions on the plain, and several of these outflows are of considerable value to the squatters.

Importance of the flood spreading over the country.

2081. Do you consider it of much importance that the flood-waters of the river should be allowed to spread over the country? It is of importance to people about Balranald and at the junction of the Lachlan and Murrumbidgee. There is a large extent of land there the value of which entirely depends on the yearly inundations by floods in the reed-beds and polygonum swamps.

2082.

Mr. G. Mair. 15 Nov., 1884.

2082. In what way does the value of land depend on inundations by floods? Because the land grows grass only after the land has been flooded. In some cases these polygonum swamps extend 10 or 12 miles from the river, and that country is of very little value except after floods; it is comparatively valueless for grazing unless it is periodically flooded.

Murrumbidgee always running.

2083. *Mr. Barton.*] Have you ever known the Murrumbidgee to run dry or become a chain of water-holes? No, the river is always running.

Effect of diversion of water at summer level.

2084. Apart from the question of navigation, in what way would the people below be affected if the water were diverted from the river at summer level? By reducing the supply of good water. When the river has been low I have known the water to be quite unwholesome in consequence of there being so many carcasses of animals in it. I have seen the river so low that my sheep could cross from my station to that of my neighbour on the other side of the river. There is scarcely a year in some part of which the sheep cannot get across. You will see by this that people below would be very materially affected if the water were reduced to a still lower level, because in many places the river would then be no longer a natural fence.

2085. I suppose if the river were not interfered with below from 1 to 3 feet below summer level those people would not be affected? Not materially.

Level at which diversion will not be injurious.

2086. *Mr. Murray.*] At what depth below the present level of the river do you think the water might be diverted without injuring the people below? If it is a mere matter of water supply for stock and domestic purposes the river might be several feet lower than it is at present; but you have to consider the importance of the navigation and the inundation of the low lands to which I have previously referred.

Navigation.

2087. Could the river be reduced below the present level without affecting the navigation? I think scarcely not—the river would not be safe for navigation if it was much lower than it is at present.

Effect of the Yanko cutting on river level.

2088. *Mr. Franklin.*] The river at the point where the Yanko cutting is made is about 300 feet wide, by a mean depth of about 10 feet, which gives about 53,000 cubic feet, and the area of the Yanko cutting is only about 200 feet, so that the cutting could only intercept 1-215th part of the entire flow of the river; this would probably lower the river by about one quarter of an inch: do you think that would affect the people at Hay? If not more than 1-200th part of the supply of water in the river were intercepted I do not think any one would object.

Quantity of water raised at Groongal Run.

2089. Have you any record of the quantity of water which you raise for the purpose of irrigation at your station? When I am pumping for the purpose of irrigation I raise probably over 3,000 or 4,000 gallons per minute. I keep the pump working all day. This year I think the pump has been working about three weeks.

2090. What is the area of Groongal Run? About 300,000 acres.

Consumption of water.

2091. Do you think the other run-holders on the river consume as much water proportionately as you do? Very few of them do any irrigation. I think there are only one or two who consume more water than I do.

2092. I suppose we may assume that all the station-holders on the river consume as much as you do for various purposes? I should say that where we irrigate we consume more than a fair proportion of water.

Tallywalka and Teryaweyna Creeks.

2093. *Mr. Donkin.*] Does the Tallywalka Creek flow into the Teryaweyna? The Tallywalka Creek is an ana-branch of the Darling, and the Teryaweyna Creek is an outflow from the Tallywalka.

2094. Do you know whether there is any water in the lake there? I believe not.

2095. How is the dam to which you have referred standing? It is standing perfectly well.

2096. Is the creek a deep one? The Tallywalka is a deep channel, and the effluence to the Teryaweyna is about 6 feet higher than the bottom of the Tallywalka, where it flows out.

Polygonum swamps near Balranald.

2097. Would not a high flood cover the polygonum swamps, near Balranald? Yes, and in times of flood all the water you could take down the Yanko would be of no consequence as affecting the Balranald country.

River traffic.

2098. *Mr. Gipps.*] What is about the value of the river traffic at Hay and Balranald? I could not state, but it is not of so much importance to Hay now that they are connected by railway with the metropolis as it is to Balranald.

Width of river.

2099. What was the width of the river at the point where you stated it was only 18 inches deep? The total of the surface of the water was about 20 yards. It was not more than 18 inches deep at the deepest part.

Inundation level at Balranald.

2100. At what height would the river have to be to flood the country near Balranald? I cannot say exactly, but probably 15 feet.

2101. Then if a movable weir 15 feet high were erected, it would answer the same purpose. Yes.

Insufficiency of Murrumbidgee waters for irrigation.

2102. *Mr. M'Mordie.*] Your idea is that there is not sufficient water in the Murrumbidgee to admit of irrigation being carried on on a large scale? Yes.

2103. Then if irrigation is to be carried on in the country between the Murray and the Murrumbidgee, the water would have to be obtained from the Murray? I suppose so.

Flood level.

2104. *Mr. Donkin.*] How high would the river be above summer level before you considered it in flood? Anything over 10 feet.

Fall from and to the river.

2105. *Mr. Franklin.*] Is there not a natural drainage northwards? By taking a north-westerly direction you get a fall as far as you like to go; if you go in a westerly direction you get a fall to the north as well; but if you go due north, taking a long course of miles, I should say the fall is towards the river.

2106. You say that in the direction in which there is a fall you do not know of any natural depression in which large quantities of water might be stored? There are none that I know of, of any size.

Height of banks.

2107. *President.*] What is the height of the banks of the Murrumbidgee? At Groongal I should say that the height of the bank from the lowest level at which I have seen the water is about 21 feet.

Mr. John Alford called in and examined:—

Mr. J. Alford. 15 Nov., 1884.

2108. *President.*] How long have you resided in this district? About twenty-one years.

2109. You have been employed in sinking wells? Yes.

2110. During the whole of the time that you have been in the district? No; for about fifteen or sixteen years.

2111. You have sunk wells on both sides of the Yanko? Yes.

2112. Have you sunk many between the Murrumbidgee and the Yanko? Yes.

2113. Were you in the district when the Yanko cutting was made? Not when the first cutting was made.

Mr. J. Alford.
15 Nov., 1884.

2114. Do you know how often water goes down the cutting? The Murrumbidgee has to be 8 or 9 feet above summer level before water will go down the cutting.
2115. Is it necessary for the river to be at that height for a considerable time before the water will run down the cutting? I think so.
Yanko cutting.
2116. As the water recedes in the river, so it recedes in the cutting? Yes.
Water lost in drifts.
2117. Do you know whether after the water goes down the cutting a certain distance it seems to lose itself? There are a number of water-holes which have to be filled; but I do not think that much water percolates through the soil.
2118. Do not you think that the water gets away in drifts? A little may soak away in certain places, but I know that the water stands for a long time in the holes.
2119. Is it not supposed that at Bundara the water gets away in a drift? I have not heard of it.
Depth of wells in the Tubbo country.
2120. What depth have you to sink wells in the Tubbo and surrounding country before you strike good water? We strike the first water at from 70 to 80 feet, but generally sink from 120 to 200 feet.
2121. Is there a large quantity of water where you first strike it? No.
Quality of the well-water.
2122. Is it good water? Sometimes it is good, but generally it is brackish; the second water is always as fresh as that in the river, and there seems to be an unlimited supply of it.
Nature of soil.
2123. What sort of ground do you sink through? Usually clay and drift. The second water is struck in drift which is as fine as flour.
2124. Is the second water always found in the same kind of drift? Yes.
Rise of water.
2125. When you strike the second water does it rise very high in the shaft? Yes, but never higher than the level at which we strike the first water; it rises to about 70 or 80 feet from the surface.
2126. Have you never known the second water to rise above the surface? No, I have not known it to rise an inch higher than the level of the first water.
2127. Do you think the water gets away in the drift at which the first water is found? No.
2128. How do you account for the water not rising any higher? I suppose that the source of the water is not much above that level. I have had tubing put down to the second water, but even then it did not rise above the level of the first water.
Source of the well-waters.
2129. Where do you suppose that the water comes from—from the present river? Not from the present river. I believe that it is an undercurrent, and that the water comes from the mountains.
2130. If that theory were correct the water would rise to the surface? I do not think that there is sufficient fall to force the water to the surface.
2131. You do not think that the water comes from the Murrumbidgee or the Yanko? No. In a well which we sunk about 40 feet from the river bank the water rose to within 80 feet of the surface, and although the whole of the flat was covered with flood-water the water did not rise in the well, therefore I assume that the water was in connection with the river water.
Limestone stratum.
2132. Do you pass through any cement bands in sinking? Sometimes we pass through white limestone.
Black clay with charcoal.
2133. Can you always tell at what depth you will get water? We can always tell when we are getting near the second water, because we pass through black clay with charcoal in it.
Underground water currents.
2134. Can you judge from the surface formation as to the depth which you will have to sink? Not always; I believe that there are different runs of water, and in some places we get the water 10 feet higher up than we get it in another place, but the depth is nearly always about the same.
2135. Have you ever struck salt water at the low level? No.
2136. How many wells have you put down in this part of the country? About thirty or forty; perhaps more.
Soil at Yanko cutting.
2137. Is that ground composed of cement where the Yanko cutting is made into the Murrumbidgee? It is sand and clay mixed.
2138. *Mr. Barton.*] Have you ever found any decayed timber in the drifts? No; but there is generally charcoal.
2139. Have you ever found any shells? No.
2140. *Mr. Franklin.*] Have you kept any record of the strata which you passed through in sinking the different wells? No.
2141. Why do you pass the first water? Because the supply is not sufficient.
2142. Do you adopt any means to keep that water out of the wells? No.
Size of wells.
2143. What is the size of the wells which you have sunk? 6 feet by 3 feet.
Depth to water.
2144. What is the depth at which you generally strike water? The deepest well which I have sunk is one of my own. It is 198 feet deep. The first water was struck at 80 feet. When we struck the second spring the water rose 110 feet in about three minutes.
2145. Has that occurred in any other well? Yes, in one which I sank for Mr. Duncan Robertson.
Exhaustion by pumping.
2146. Do you think it possible to exhaust the supply of water by pumping? No.
2147. Are there many such wells on the Yanko? Yes, I have sunk five or six wells like those on the Yanko.
Effect on supply of larger size of wells.
2148. Suppose that you were to enlarge the size of the wells to (say) 12 feet by 6 feet, do you think that you would get the same result? I think that there would be just as large a supply of water in larger wells.
2149. *Mr. Donkin.*] Have you ever found any large water-worn stones in sinking the wells? No, I have never found any stones larger than eggs.
Variation of water level.
2150. Does the height of the water in the wells vary? No; it is not affected by floods in the river, and it keeps about the same level winter and summer.
Time employed to sink a well.
2151. *Mr. Gipps.*] How long does it take to sink the wells? I have recently sunk one 102 feet in depth in three weeks; there were three men employed besides myself.
Cost.
2152. What is about the cost per foot? I find everything, and I get from 30s. to 35s. per foot.
Terms of contract.
2153. *President.*] The terms of your contracts are that you have to do the sinking and supply the timber, and strike water before you are entitled to any payment? Yes.
Wells marked on map.
2154. Could you mark on the map the localities of the various wells which you have sunk, and state their depth? Yes.
Effect of pumping.
2155. You said just now that you did not think that the water in the wells could be lowered by pumping? By pumping very hard all day you might get the water down a couple of feet, but in about two minutes it would rise to its ordinary level.

Mr. John M'Kersie was examined:—

Mr. J. M'Kersie. 15 Nov., 1884.

2156. *President.*] You are a selector on the Yanko Creek, I believe? Yes.
2157. Have you been residing there long? For nearly ten years.
2158. Do your selections front the creek? Yes.

The Yanko Creek.

2159. Have you found that the water has run down the Yanko for any great distance every year until the last? No; it has not reached us since 1879.
2160. How many miles down the creek are you? About 70 miles.
2161. Then you are below Yanko Station? Yes.
2162. Do you depend principally on the Yanko water for your stock? Yes, for the frontage blocks.
2163. What means of supply have you on the other blocks? Wells and tanks.

Quality of well-water.

2164. Do you get good water by sinking? Very good.

Depth to water.

2165. At about what depth? From 50 to 75 feet on many blocks.

Quantity of water.

2166. In what quantity? I have no idea of the quantity, but it is sufficient to water between three and four thousand sheep at each well.

Description of land.

2167. Have your frontage blocks been rendered almost useless for the want of water in the creek? Yes.
2168. Have you any portion of the country known as the Yanko Flats in your selection? Yes.

Quality of land.

2169. It is very good land? Excellent.
2170. Capable of growing all sorts of cereals? Yes, provided it is irrigated.
2171. Will it grow maize? I have had no experience in growing maize. The land will grow wheat and oats—in fact it is rich enough for anything.

Height of flat above Yanko.

2172. At what height above the bed of the Yanko is the flat generally? 20 to 25 feet.

Raising of water.

2173. Suppose a stream of water were to flow down the Yanko, in which way would you carry it on to the land? It could only be done by machinery.

Dams.

2174. Are there any dams where you are on the creek? Yes.
2175. Below you? Above and below.
2176. They have a by-wash? Yes.
2177. Is it your opinion that dams with a by-wash or overshot dams would answer the best? All the dams should be overshot.

Evaporation.

2178. Do you not think that the evaporation would prevent the supply from being permanent unless where there is a great depth of water? Not if the creek were to run every year; it would in the course of four or five years.

Permanent supply by overshot dams.

2179. Suppose you got a supply once every two or three years? An overshot dam 4 or 5 feet high would give a permanent supply for two years.

Storage of water for irrigation.

2180. Suppose the water flowed down the Yanko every year, could you store enough for irrigation to any large extent? I think so.

Effect of water running down the Yanko a month in a year.

2181. Would the selectors be satisfied if they had the water running down the creek for a month in the year? Yes, perfectly satisfied.
2182. That is without having a continuous stream? Without a continuous stream.
2183. Would such a supply greatly benefit the property of selectors in your neighbourhood? Yes, very much.
2184. Do they depend on their crops or on their stock principally? They combine agriculture with stock-raising.

Area of land held by selectors.

2185. What area of land do the selectors hold down there? From one to six or seven thousand acres.
2186. They combine depasturing stock with cultivation? Yes.
2187. If a scheme to supply water down there were carried out, would it prevent any of the selectors from leaving the Yanko? I believe it would.

Selectors leaving the district.

2188. Do you think that the hardships they have had to go through have had the effect of causing any selectors to leave the district? They are enough to frighten any one.

Selectors would irrigate.

2189. *Mr. Barton.*] Suppose the stream of water running down the creek were sufficient to provide for irrigation, do you think the selectors would avail themselves of the water for that purpose? I think they would.

Their willingness to pay a rate.

2190. In that case would they be willing to pay an annual rate? Yes, they would.

Value of land.

2191. Do you think that the effect of having running water down the creek once a year would enhance the value of the land on both sides of it to a considerable extent? Yes, very much so.
2192. To what extent? Land was bought on the Yanko three years ago for £2 6s. an acre, and to-day I do not suppose that you could get more than 30s. for it.
2193. If the water in the creek ran through once a year, what effect would that have upon the value? It would increase it to from £2 10s. to £3.

Width of Yanko cutting.

2194. *Mr. Murray.*] Do you know the cutting of the Yanko? Yes.
2195. Do you consider that it is large enough to supply the requirements of people on the banks of the stream? No.
2196. Do you know the proposed cutting? I have seen a section of it.
2197. What width of cutting would be sufficient, do you suppose, to supply a stream of water the full distance down the creek? I have no idea.

Enhanced value of property.

2198. To what extent do you think a constant supply of water would enhance the value of your own property? I should say that it would make it worth £2 10s. or £3 per acre.
2199. At what do you at present value it? I do not suppose that it is now worth more than 30s., in the present state of the market.

Payment of a rate.

2200. You would be quite satisfied to pay a liberal rate for the interest which would be required on the money needed for improvements? I would.
2201. *Mr. Barton.*] Are you aware that in some countries, California for instance, the effect of an unlimited supply of water has been to increase the value of land from 5s. an acre to £30 an acre? I have read so.
2202. *Mr. Franklin.*] You do not think it would be possible to improve the value of land here in the same ratio? It might be, in the course of years.

Sectional area of Yanko Creek lower down.

2203. Is the general area of the Yanko, as a water-carrying creek, much larger lower down than at the inlet? Much larger.
2204. In what proportion larger? Forty or fifty times as large as could be supplied through the inlet.

2205. The comparison might be something like the neck of a bottle to the bottle itself? The proportion would be much greater. Mr. J. M'Kersie.

2206. What is the length of the work which has been made by cutting—the length of the conduit—until it is lost in the creek? The creek has been made by cutting more or less for 14 miles, and some parts of the creek have been deepened. 15 Nov., 1884. Length of cutting.

2207. Could you give us any idea of the proportion which the inlet to the creek bears to the creek itself? I should think that the creek is capable of carrying forty or fifty times more than the present cut is capable of supplying. Water-carrying capacity.

2208. What distance would it be necessary to make the cutting to connect the Murrumbidgee with the full carrying capacity of the creek? About 2 miles, if I remember aright, according to Mr. James's plan.

2209. *Mr. M'Mordie.*] From the new inlet? No, the old.

2210. *Mr. Donkin.*] Do you know the Cudal Creek? Yes. Cudal Creek.

2211. Does any water run down it in flood-times? In high floods. If it ran through the Cudal Creek the flow would be very much greater than through the cutting.

2212. *Mr. Gipps.*] To guarantee an equitable allotment of water would it not be necessary to establish a Board of Trustees? I think so. Board of Trustees.

Mr. William Mooreland was examined:—

2213. *President.*] You are a selector, living at Yanko Creek? Yes. Mr. W. Mooreland.

2214. Do you live near Mr. M'Kersie? About 2 miles from him.

2215. You have heard his evidence? I have.

2216. Do you agree in all that he has said? I do. 15 Nov., 1884.

2217. You consider that the land down the Yanko, especially the flats, would be enhanced in value by a supply of water? I do. The land is good enough to grow anything.

2218. Have many selectors left? Yes; and a great many more would be glad to sell out now if they could get the value of their property. The rainfall seems to go down about as far as the water flows. Rainfall on Yanko.

2219. Do you consider that the conservation of water would attract larger rainfall? I do.

2220. Is there anything which you wish specially to place before the Commission? No; only this, that we want the water as soon as we can get it. Immediate want of water.

2221. *Mr. Barton.*] And you are willing to pay for it? Yes, if there is a rate levied, but not to subscribe the money and then pay a *pro rata* rate. Let the Government find the money, and we will pay the interest on it. Payment of rate.

2222. *Mr. Gipps.*] Would you have the matter placed under a Board of Trustees? No. Board of Trustees.

2223. *Mr. Franklin.*] How far is your holding down the creek? About 60 miles from here.

2224. With a small rise in the river, such as at present, or even with the river 2 feet higher, I suppose you would get scarcely any benefit from the quantity of water which would flow down the creek? No; it has not been down for five years. It went as far as Bundurce three years ago. Distance reached by the water in Yanko.

2225. Do you remember the height of the river at that time? I think it was about 19 feet.

2226. Above summer level? Yes.

2227. You do not take any record? We cannot down there.

2228. Is the reason that the water does not reach that distance, that the opening is not large enough to allow a sufficient discharge from the river? Just so.

2229. The Colombo would take all the water that flows through the cutting? The flow is to the Yanko more than to the Colombo—more to the right than to the left. When there is a flood there is water enough to fill both creeks. Waterflow to Yanko and to Colombo.

2230. What is the distance from the mouth of the cutting to the Colombo Creek? About 20 miles.

2231. *Mr. Murray.*] What do you consider would be the enhanced value of your property if you had a supply of water? It would be increased from about 20s. to £2 10s. I do not think that land can be sold now at any price. I have given £2 for land there with 15s. an acre to pay up. Enhanced value of property.

2232. *Mr. Donkin.*] The country is open plains? There is a good deal of boree in it.

2233. There is not much of it heavily timbered? No. Features of country.

2234. Has the timber any effect upon the rainfall? If the water were to flow down the creek, that might affect the rainfall. There is a good deal of pine and box in the back country, and there it is as dry as in parts where there is no timber. Rainfall.

2235. In times of heavy rain where does most of it fall? Sometimes more on the creek, sometimes more upon the timber—I do not think there is any general law.

2236. You do not think that you get more rain in the country where the trees grow? I think that we get more showers on the creek than further back.

2237. *President.*] Do you attribute that to the creek as well as to the timber? Yes.

2238. *Mr. Donkin.*] Has any ringbarking been done? Timber is too scarce for that.

Mr. Martin Brennan was examined:—

2239. *President.*] You live on the Yanko? Yes. Mr. M. Brennan.

2240. How far down? About 30 miles.

2241. Have you lived there a long time? About eight years.

2242. You have heard the evidence given by Mr. M'Kersie and Mr. Mooreland? Part of it. 15 Nov., 1884.

2243. Do you consider that your ground would be much improved in value if you had a good supply of water? Yes. Value of ground

2244. During the last four or five years how many times has the water run down to your selections? On an average there were three overflows in the year, except in 1878. How often the water reached the selections.

2245. How often have you had the water down this year? Three times.

2246. Is it sufficient to fill your tanks? No; the holes in the creek supply me.

2247. You have not attempted to irrigate? No. One year the creek went totally dry, and I used well water. Irrigation.

2248. What sort of water is it? Very good. Quality of water.

Mr. M. Brennan. 15 Nov., 1884.

2249. Has it any connection with the creek? I think the water I have tapped there has been tapped in all the wells within a radius of 20 miles.

Well connected underground with Murrumbidgee.

2250. Do you think it is connected with the creek? I think it is connected with an underground drift from the Murrumbidgee. Shallow wells have struck the water; my well is 61 feet deep; deeper wells supply a larger quantity. The wells which strike the lowest drift give any quantity.

Enhanced value of property.

2251. How much would your property be increased in value if you obtained water in any quantity? I could not say. Land will rapidly increase in value as water is permanent.

2252. Do you grow crops to any great extent? No.

2253. Would you if you were able to irrigate? No; I am not an agriculturist.

Quality of land.

2254. The land is capable of growing crops? It is very good land for cereal crops.

2255. What extent of land have you? My brother and I have 2,800 acres.

2256. You have some of the Yanko flats? About one-third of it.

2257. That land will grow anything? I think the timber land is better for growing crops than the alluvial flats; the flats are stronger pasture land.

Nature of soil.

2258. What is the soil? Black clay. I have never seen any grain crops tried on it.

2259. Have many selectors sold out in that neighbourhood? A few.

Effects of want of water.

2260. Would any of them stay if they had a better supply of water? Some would. Want of water has not been the main cause which has led many to sell out, but want of water will, I believe, cause others to sell out.

2261. It is absolutely necessary that the settlers should have a better supply? Every one feels it to be so.

2262. Do you know the country where Mr. M'Kersie lives? I have been as far as Jerilderie. They need the water to a greater extent there than we do. The further you go down the more is the water required. The dry bed of the creek absorbs the water as it leaves the Murrumbidgee, and the water diminishes in that way the further you go down until it ceases to run altogether. Once the bed of the creek is saturated a small quantity of water will be enough to make a flow.

Absorption of water in the creek-bed.

2263. Would the bed of the creek absorb much? Once it is dry it drinks up more than flows down, and it is not till the bed of the creek is well wetted that there will be any flow.

2264. When you have had a plentiful supply of moisture in the creek have you noticed that you get more thunder-storms? I cannot say that I have. I do not think that timber brings rain.

2265. Does water? Water produces fogs; but thunder-storms come north and south, and may extend a couple of miles across. The country will be quite dry on each side. I was told by an old resident that in

Murrumbidgee partly dry in 1839.

1839 the Murrumbidgee was running at Jugiong, and that it was quite dry 15 miles this side, at Oakey Creek; it was running again at Jones's Flat 6 or 8 miles this side of that; it was running again at Buck's Island, 8 or 10 miles beyond Wagga; and again at Deepwater.

2266. How far down is that? Mr. Devlin's, 30 miles above Narrandera. Then the bed of the river was dry until you got to Burrabogie; it was running again below Burrabogie.

2267. Was it a sandy bed where the water was not running? Yes; and the water was procurable in the sand. In 1851 I was able to walk across the Murrumbidgee, although there was some water in it.

2268. Where was that? Above and below Gundagai.

2269. At what time of the year was it? In December, January, February, and I think later.

Loss of water in drift.

2270. Your theory is that the water is lost in the sand? Yes, in the drift.

2271. It does not sink into the bed of the river and reappear at another point? It sinks into the drift, which has a clayey and rocky bottom. At the time at which I refer, it was running at Hay at a lower level.

Mr. John Witcombe was examined:—

Mr. J. Witcombe. 15 Nov., 1884.

2272. *President.*] You are the Mayor of Hay? Yes.

2273. And you have come from Hay to meet the Commission? Yes.

2274. The people living down the river are, I understand, rather anxious as to what is to be done in diverting water from the Murrumbidgee? I think it is in consequence of their anxiety that the Commission meet here to-day.

State of river at Hay.

2275. Has the Murrumbidgee been very low at Hay this year? About the beginning of the year—in February and March—it was so low that I could step across it, and we had to concentrate the flow to supply our water-works.

River-bed.

2276. Is the bed of the river composed of sand? On one side.

River dammed.

2277. I suppose there would be water all through the sand? We did not try it; we partly dammed it with the sand.

2278. But still it would percolate through? I suppose a little would.

Width of stream.

2279. What was the width of the stream flowing when you dammed it? About 7 feet. I jumped across it one day.

Depth of stream.

2280. And what depth? About 3 feet, running amongst logs. We dammed it in a narrow place where there was a sand-drift, and by that means we raised it about 2 feet, directing the water into a channel which supplies our water-works.

2281. Were you at Narrandera at that time? No.

State of river at other points.

2282. Could you form any idea of the quantity of water which was flowing past Narrandera at that time? No.

2283. Or at any other point of the river besides Hay? No.

2284. Have you any knowledge as to what proportion of water is lost by percolation through the bed of the river, or otherwise, between Narrandera and Hay? I do not think that there is very much lost. There is one place above Hay where teams are crossed to avoid paying the toll which is levied on the

Hard cement bottom.

bridge; there the bottom is very hard cement.

2285. But there may be points along the river's course where the water may get away—have you heard the evidence given by John Alford this morning? Yes.

2286. It is just possible that a great deal of water may leave the river? Yes.

2287. And it may get away between Narrandera and Hay? Yes.

Water lost between Hay and Narrandera.

2288. Have you any idea that it does? I have seen the river running at Wagga, at Narrandera, and at Hay; and at Hay the volume of the water would be very little less than at the other places.

2289. You accompanied the Commissioners yesterday to the proposed Yanko cut? Yes. 2290.

Mr. J. Witcombe.

15 Nov., 1884.

2290. And you saw the plans and heard the various ideas expressed on the subject? Yes.

2291. Do you think if a cutting was made as proposed—1 or 2 feet above summer level—to divert water into the Yanko, that would materially affect the river at Hay? Yes.

Effect of Yanko cutting on supply at Hay.

2292. The proposal being 1 or 2 feet above summer level? It might draw off all the water and would certainly divert the course of the river if made 2 feet below summer level as proposed.

2293. If the diversion of the water was controlled by sluices, would the people of Hay have much objection? They would not object to anything being taken above navigation point.

Water Trust.

2294. Would it be more satisfactory if the matter were placed under some definite head? It would be much more satisfactory; it is the opinion of people on the lower parts of the river that there should be a Trust.

Objection against diversion at summer level.

2295. There is a great objection to diverting the water when the river is at or near summer level? There is; we know from past experience that the water would be so much polluted as to be unfit for use for domestic purposes.

2296. The small cutting proposed would not affect the flood-waters? No; but if the diversion was made as has been suggested, considering the great difference in the height of the railway levels at Narrandera and Hay, there is great danger that the interests of Hay will be seriously damaged.

Difference of level at Narrandera and Jerilderie.

2297. You are referring to the railway levels? Yes, as given in the time-tables, which we assume to be correct. We find that we have 574 feet at Narrandera, and at Jerilderie, which is 65 miles distant, the height is 361 feet. There is therefore a fall all along the creek from here, and if the water does not flow it must be owing to the faulty construction of the channel.

Fall of Yanko Creek.

2298. You think there is a fall of about 4 feet to the mile? It is over 3 feet.

2299. You do not know the difference between the railway levels and the river or water levels? No, but I should think there is not more than a difference of 50 feet. That is a matter to be ascertained by the engineers.

Level at Darlington.

2300. Suppose we reduce the difference of the railway levels by one-half, that would give a fall of 2 feet or 1½ foot to the mile all the way down? Yes, at Darlington, which is 60 miles from here, the level is 412 feet.

Level at Hay.

2301. What is the level at Hay? I think 305 feet, but I cannot say for certain: it is not given for all the stations.

2302. How far is it from Narrandera to Hay? 101 or 102 miles.

Fall of Murrumbidgee.

2303. By comparison with the level at Darlington it would appear that you have a 3-feet fall? We do not know that we have the same at Hay—we do not think we have so much. If we had, it would bring us down a long way below 300 feet. The fall of the country seems to be towards the Murray River. Echuca is 320 feet, and Deniliquin about the same.

Depression of country between Murray and Murrumbidgee.

2304. As a matter of fact we have it in evidence that the depression in the country between the Murray and the Murrumbidgee is generally lower than the banks of either of those rivers? Yes, the Yanko Creek goes into the Edwards, which flows into the Murray; and that shows that if a large cutting were made and the water were admitted to it without regulation the ordinary flow of the Murrumbidgee might be diverted down the Yanko, and we at Hay should be left with the floods-waters only.

2305. When the Murrumbidgee is in heavy flood, the great volume of the water flows past Hay? Yes, and runs to waste.

Principal fall.

2306. That would show that the principal fall and largest outlet is at Hay? Yes.

2307. If a cutting were made under the Yanko, portion of the flood-waters would be diverted from Hay? Yes, there is plenty of water in flood-time if only it is taken at that time.

No harm to Hay if no water diverted under summer level.

2308. Having seen the cutting proposed and the quantity of water which is likely to be taken down it, if the cutting were governed by sluices under the control of a proper Water Trust, no water being diverted when the Murrumbidgee is below summer level, do you consider that there would be any material harm done to the people down the river? I do not think so, if only they get their proper quantity, but there are a hundred other places in a similar position to the Yanko.

2309. *Mr. Franklin.*] Your comparison of the levels between Hay and Narrandera is taken from the railway levels? As given in the time-table.

Railway station levels and river levels.

2310. You take Hay at (say) 300 feet and Narrandera at a much higher elevation, but is not the railway station at Narrandera a long way above the river level? I should think not more than 50 feet higher.

2311. *Mr. Donkin.*] What is the height of the railway above the river at Hay? About 4 feet above high-water mark.

2312. *Mr. Franklin.*] In considering the difference between Narrandera and Hay, we must consider the difference between the river levels at the two places? Certainly, your engineers can ascertain the levels.

River traffic.

2313. *Mr. Gipps.*] What was the amount of the traffic borne by the river between Hay and Narrandera before the railway was opened, and that which has taken place since? I will supply that information when I return my evidence after revision. (*Appendix* M.)

Objection against erection of a weir.

2314. *President.*] Suppose a weir were constructed across the Murrumbidgee near the cutting into the Yanko to raise the height there, would there be any great objection to that? Yes, very much; those lower down the river would object to it.

2315. On what ground? Because it would turn their water away.

2316. I am supposing that the cutting is protected by sluices and under the control of a proper Trust? I think there would be a great deal of difficulty in deciding the quantity to be sent down.

2317. Suppose that could be satisfactorily arranged, would the interference with the navigation be a matter of great objection? I think so. I think the best plan would be to send down sufficient in flood-time.

Dam across the river at Hay.

2318. *Mr. M'Mordie.*] I think you said that at Hay you put a dam across the river to divert the water for the supply of the town? Yes.

2319. Was objection raised to that? No. We did not put the dam quite across, but only so far as was necessary to make the water run in the direction which enabled us to take what we required.

Navigation.

2320. *Mr. Donkin.*] Does that interfere with navigation? There is no navigation in the summer; it is just about stopping now. I believe there are two steamers between here and Hay, and unless there is another rise, they will be the last this season.

Proposal to divert Snowy River waters.

2321. *President.*] Have you heard of a proposal to divert some of the Snowy River waters into the Murrumbidgee? Yes.

2322. That, I suppose, would be very acceptable? Yes; but I do not think that it would increase the supply at the time when we want it most.

Mr. J. Witcombe. 15 Nov., 1884.

2323. How is it that it increases the volume of the Murray? The Murray keeps up a little longer.
2324. Do you know that there is very little snow-water flows into the Murrumbidgee? Not so much as into the Murray.
2325. If fifty times as much as now flows in were diverted, it would appreciably increase the volume of the Murrumbidgee? Yes.
2326. It would to a great extent make up the deficiency, perhaps more so, by the diversion of water into the Yanko? For a time. Sometimes it happens that the dry season is prolonged to nearly June.

Locking of Murrumbidgee.

2327. Then it would have no effect? No. What we want down below is that the Murrumbidgee should be locked from its mouth, then there would be plenty of water for all.
2328. You would strongly recommend that the river should be locked from its mouth upwards? Yes.
2329. And the water which now runs to waste could be used? Yes.

Diversion of flood-waters only.

2330. *Mr. Franklin.*] Suppose that by the construction of a temporary or movable weir we were to raise the water at summer level for a sufficient time as to send it down the Yanko, would you suffer then? According to the evidence given here to-day that would be no use to them; if you only sent down the flood-waters that would not affect us.

Necessity of dams below Hay.

2331. The inlet is not sufficiently large for a quick discharge out of the river into the creek? There would not be any objection to supplying the creek if the flood-waters were sufficient. If dams were placed below Hay, there would be plenty of water for all. Sometimes the stream is so small that the sheep and cattle and the population at the stations make the water unfit for use for drinking purposes at Hay.

Probable effect of the cutting upon the course of the river.

2332. *President.*] You desire to give some further information as to the probable effect of a cutting upon the course of the river? Yes. Three years ago the river 5 miles below Hay ran round a block containing several hundred acres. Some of the steamers were blocked in the river, and the passage which was made to extricate them was so widened by the river that the water ceased to flow in its old channel, and left a block of land on the other side of it. The land belonged to Mr. Colin Simson, who had to turn it over to the owner of the property on the other side. That shows that any large cutting in the banks may have the effect of diverting the course of the river.

Mr. John Andrew was examined:—

Mr. J. Andrew. 15 Nov., 1884.

2333. *President.*] You reside at Hay? Yes; I have lived in the district over twenty years.
2334. You are the owner of the *Riverine Grazier*? Yes.
2335. You accompanied the Commissioners yesterday to view the proposed cutting into the Yanko? Yes; I came as one of a deputation from the people of the town and district of Hay.

Effect at Hay of the diversion of water into Yanko.

2336. The reason being that it is feared that damage might be done to their interests by diverting a portion of the water from the Murrumbidgee down to the Yanko? Yes; from the scheme as reported to us we felt certain that if it were carried out we should get no water at the time we most needed it. This year the water was flowing by in such small quantity that we had to make a small dam to get water for the town.

Waste of water.

2337. That fear would be removed if the water were never diverted except when there was a large quantity flowing down? There is an abundance of water goes down the river in the course of the year—almost enough to irrigate the district.
2338. *Mr. Franklin.*] And most of it runs to waste? Yes, every year.

Proposal to lock the river.

2339. *President.*] You have heard what Mr. Witcombe has told us about locking the river—do your opinions coincide with his? Thoroughly.

Value of land.

2340. And the water which now runs to waste could be conserved for use if the river were locked? Yes, I believe the value of this Riverine country would be increased twenty-fold. There would be irrigation to supply food for the stock in dry seasons, and the carrying capacity of the land might be increased from one sheep to 5 acres to three or four sheep to 1 acre.

Control of Trust.

2341. Having visited the locality, seen the plans, and heard what has taken place, I ask you if the diversion of water proposed under the control of a properly governed Trust would cause any harm to arise? If the Trust were appointed by people interested all along the river I do not think any harm would arise. If the matter were in the hands of a Department hundreds of miles away I should fear harm would arise. Under a Trust elected by the people interested, water could be dealt out to the Yanko people and anybody else who might require it with very great safety.

Constitution of Trust.

2342. Would you suggest that the Trust should comprise all who are interested in the Murrumbidgee and the Yanko combined? I think it should include all who are interested in the different effluents of the Murrumbidgee.
2343. Would it not be well to make a number of small Trusts? In actual practice it might be so, but it does not strike me that that would be the better course at first. If there were several Trusts over one river their various rights would have to be defined by statute, whereas if there were a general Trust over the whole river there would be no clashing of interests, and less legislation would be required.
2344. The Trust should not comprise people who lived at such a distance from the watercourses that they could receive no benefit? No—only of people who were interested. There should be a small tax upon the land, and all who paid rates should have a right to vote for a body which would be something analogous to a District Municipal Council.
2345. And the works should be undertaken by that body? Yes.
2346. Would you give them power to borrow money? Yes; and to levy tonnage dues on vessels going up and down the river.

Diversion of snow-waters into Murrumbidgee.

2347. You have heard of the proposal to bring some of the snow-waters into the Murrumbidgee? A very good thing it would be. At Deniliquin, where I lived for some years, the snow-waters usually came down in October, but we do not find that they make much difference to the Murrumbidgee. The snow-water always came down perfectly clear, and there were little bubbles on the surface of the stream. When the winter has been severe and the fall of snow heavy we have had the snow-water down the Murrumbidgee, but the occurrences have been few and far between.

Supply at Hay.

2348. Would the additional volume of the river from the snow-water remove the fears entertained of diminishing the supply at Hay? It would be very desirable if the snow-water which now runs to waste could be diverted into the Murrumbidgee.

The Hay water supply.

2349. The people of Hay have carried out a scheme for supplying water to the town? They have.

Mr. J. Andrew. 15 Nov., 1884.

2350. Is the supply used to any great extent to irrigate paddocks and gardens? The water is raised a height of 50 feet, and the cost of raising it is greater than can be paid for ordinary purposes of irrigation. The Chinese gardeners grumbled at having to pay the amount charged per annum. The cost of raising the water 50 feet high is 11d. per 1,000 gallons. Our surveyor calculated that they were not paying more than 3d. per 1,000 gallons, and when we placed meters to govern their supply they would not pay the cost. Nearly every house irrigates to a small extent, and now there are beautiful gardens full of flowers where before nothing would grow. The streets were planted about the same time, and now some of the trees have made so much growth that 100 men could stand in the shade of a single tree.
2351. It is only a matter of percentage as to whether you apply it to agriculture? That is all.
2352. Have you any idea what your water scheme cost? About £5,000, and we have spent £2,000 more lately. We also want to lay down larger pipes. Cost.
2353. The water is pumped from the Murrumbidgee? Yes.
2354. Does the quantity withdrawn affect the Murrumbidgee in dry times? It nearly all runs back again into the river. Effect on Murrumbidgee.
2355. The consumption for domestic purposes and for irrigation would not all go back? A great deal percolates through the soil.
2356. Have you any idea how much you pump per day or week? I will obtain the figures from the Mayor and return them with my evidence. (*Appendix* N 1.) I have heard several questions about summer level. The term is indefinite, and indicates different levels at different places. At Hay, however, it has a definite meaning, for when the bridge was built a gauge was put on, and summer level is there a fixed point. Quantity pumped per day.
2357. What is that point? About 24 feet below the highest flood. Summer level at Hay.
2358. Have you any records of the height of the river which would be of service to the Commission? The record has been taken twice a week and can be compiled from the newspapers, in which they have been published for the last ten years. I will supply the information. (*Appendix* N 2.) Some question has arisen as to the rise in the river. I have noticed that while the river is confined within the low banks the rise may be very rapid, but after it overflows it does not rise beyond an inch an hour; and when it overflows the high banks it does not rise one inch in twenty-four hours. A rise at Wagga usually takes three weeks to come to us. Records of height of river.
2359. Does the water lose much in volume between Wagga and Hay? It takes a considerable rise at Wagga to make any rise at Hay. Loss of water.
2360. Do you think that much is lost by soakage? There may possibly be a loss by soakage; it is very likely that there is some drift from the bed of the river. Soakage.
2361. *Mr. Franklin.*] Are you aware of any point where there is a high flood level within the banks marked for gauge purposes? On the bridge. I desire to say that the rise from Wagga takes ten days to come to Hay. Flood level mark. Velocity.
2362. Are you aware that there is any point nearer Hay where a high flood is kept within the banks which would be available for measuring purposes? There is a point near my house where the water comes up to the bank and does not overflow, but then there is a low bank on the opposite side. I do not know of any such point as you describe suitable for measurement. When there is any high flood it makes a perfect sea for miles out. Flood level mark nearer Hay.
2363. Do you know the velocity of the river when it is at a low level? No, but I have known it so low that you had to look closely to see it trickle over the sand. Velocity at low level.
2364. Even though it is confined to a narrow channel? Yes; it has seemed to me as if all the water brought down could then be carried through a 12-inch pipe without any rapid flow.

SATURDAY, 15 *NOVEMBER*, 1884.

At Jerilderie.

Present:—

MR. BARTON, M.P.,
MR. DONKIN, J.P.,
MR. FRANKLIN, C.E.,
MR. GIPPS, C.E.,
MR. LYNE, M.P.,
MR. MURRAY, M.P.,
MR. M'MORDIE, B.E.

R. BARTON, ESQ., M.P., IN THE CHAIR.

Mr. Evan Jones, selector, called in and examined :—

Mr. Evan Jones. 15 Nov., 1884.

2365. *Chairman.*] Where do you reside? On the Yanko Creek.
2366. Can you give us any evidence with respect to the Yanko Creek? About thirteen months ago I and two others were sent by the Yanko residents to see if there was any obstruction in the creek which prevented the water from coming to us. We followed the creek right up but we found no material obstruction. There seemed to be a great insufficiency of water. There has not been any running water in Yanko Creek, where I reside, for four years.
2367. On what part of the creek do you reside? In the middle of Sir Samuel Wilson's Yanko Station; about 2 miles from the Wilson Post Office, and about 60 miles below the junction of the Yanko Creek and the Murrumbidgee. The Yanko Creek has not run into the Billabong since I have been in New South Wales—that is ten years. Since the creek has been dry the rainfall has been diminished by at least one half, and the value of the Yanko land has been reduced by one half in consequence. Yanko Creek. Rainfall.
2368. From what you saw when you went up the creek, do you think that by widening the cutting or straightening the creek you could get a sufficient supply of water? I was very much disappointed when I saw the cutting, considering that such a large amount of money has been spent on it. The only means by which we can get water is by deepening the cutting 3 feet, widening it 8 feet, and removing the roots and snags. Deepening of the cutting.
2369. At what level do you think the water ought to be taken from the river? Three feet below the bottom of the present cutting. There was very little water in the cutting when I was there, notwithstanding that there was a good stream in the river. Diversion level.

2370.

Mr. Evan Jones. 15 Nov., 1884.

2370. Suppose that the cutting were made 10 feet or 11 feet wide, would that be sufficient to allow the water to run through when there was an ordinary rise in the river? It would, but there must be a flush in the river to force the water down so far as to the place where I live.

Water supply once a year.

2371. Would the wants of the people in the lower parts of the creek be fairly well supplied if the water were run through once in every season? Yes, that would be satisfactory—no one would have any cause to cry out for want of water. If a good supply were run through once a year the creek would retain a sufficient quantity for the rest of the season. I have no hesitation in saying that, because I know that the holes in the creek will hold water for nine months at a time.

Value of land.

2372. Would the value of the land be materially enhanced if you got such a supply of water? Unquestionably so.

2373. What is the value of the land which you occupy? Three years ago it was worth £2 an acre, but now I could not get 25s. for it—no one would buy it. It would be double its present value if we had a regular supply of water.

Irrigation.

2374. Do you think that many people would use the water for irrigation? Some might, but I do not think that the majority would. All the selections have very narrow frontages to the creek, and by cutting up the frontages for the purpose of irrigation we should deprive the stock of access to the creek, because any roads which might be formed would be so narrow that they would soon be entirely destroyed by the sheep traffic.

Payment of interest.

2375. Do you think the selectors would be willing to pay their share of the interest on the cost of making provision for a regular supply of water? I have not heard any one raise any objection to the proposal when it has been mooted. The amount which we should have to pay would be very slight compared with the great advantage which we should derive. I have spent more money to provide means for raising water from the creek to keep my stock supplied than would pay my share of the cost of the cutting twice over. I do not think that there would be a murmur from any one against a rate to pay the interest on the cost of the work.

Local Water Trust

2376. Would you be in favour of the constitution of a local Water Trust to carry out the works and to regulate the supply of water? Decidedly.

Execution of work.

2377. Would you be in favour of the work being done by a Trust or by the Government? It would not matter to us by whom it was done.

2378. Do you not think that a local Trust would carry out the work more economically and effectually than the Government would be likely to do? I have no doubt that it would, because I am aware that there are men in our locality who would be prepared to undertake to do the work at once, and who would do it in much less time than the Government.

Dams.

2379. You are aware that there are a number of dams on the Yanko Creek? Yes.

2380. Do you think that it is necessary to dam the creek to ensure a supply of water? I should say nothing against dams as long as they were constructed so as not to throw the water over the banks of the creeks. All dams should be overshot dams. The Coree dam threw the water over the flats, where it was of no use to any one. The country is not very well adapted for the construction of overshot dams. Ordinary dams with proper by-washes leading into the creek would be the least expensive, and I do not think that any one would object to them. There is not a man on the creek who would object to dams if properly constructed. We do not wish to see the water go to waste. A dam 3 feet 6 inches high will throw the water back 3½ miles. The more water is conserved in the creek the more rain we shall get.

Diversion into other creeks.

2381. Are there any other creeks into which it would be advisable to divert the water? The water will run from the Yanko into the Billabong, supposing that the stream is sufficient to fill the dams above that point.

Wells.

2382. Have you had any experience in well-sinking in the district? I have sunk seven wells on my property.

Quality of water.

2383. With what result? I have obtained fresh water in three, and hard and sweet water in the others, but the water in all can be used even for domestic purposes.

Depth to water.

2384. At what depth did you get the water? From 60 to 97 feet.

2385. Is there any difference in the rise of the ground between the wells where you strike water at 60 feet and at 97 feet? In the deeper wells I think we strike the water at a lower level, as it rises 30 feet when we strike it. It does not rise to that height in the shallow wells. We prefer to strike the water at from 80 to 90 feet, and if the wells are properly slabbed we can hardly exhaust the supply when we get water at that depth.

Supply from deep wells.

2386. Then you have an unlimited supply in the deep wells? Yes. It would be impossible to sink the wells any deeper, as the flow of water is too great.

Nature of strata.

2387. What is the nature of the strata? There is no rock—it is all alluvial deposit. The first 20 feet is through whitish clay; then there are from 15 to 20 feet of a sort of burnt clay; then there is a bed of gravel; then a bed of sand as fine as dust; then there is another bed of clay, and after this another bed of coarse gravel. This bed varies from 15 feet to 30 feet in depth. If we get this bed 30 feet in depth we know that we are sure to get a good supply of water in the bed of fine gravel underneath.

Fossils.

2388. Have you ever found any petrified wood or shells in the drift? We have found pieces of partly decayed wood, and I have found roots which appear to me to be the roots of ferns. We have found shells like cockle shells, only larger. I believe that they are marine shells.

Overflow from Cudal Creek.

2389. *Mr. Gipps.*] What was the height of the river when the Yanko Creek flowed into the Billabong? I do not think the water came down the Yanko cutting—I think it was an overflow from the Cudal Creek, which ran a banker. The race ought to have been made into the Cudal Creek, in which there is a good fall.

2390. From what source does the Cudal Creek derive its supply? From the flood-waters of the Murrumbidgee.

Diversion o flood-water into Cudal Creek.

2391. Suppose the flood-waters were directed into the Cudal Creek, would you get it quicker than through the Yanko cutting? Yes, fifty to one. There is a fall all the way in Cudal Creek, whereas there is very little fall in the Yanko. To be of any use the Yanko cutting ought to be deepened 3 feet, and ought to commence 3 miles further up the river.

Swamps.

2392. Are there any large depressions in the Cudal Creek country in which water might be stored? I do not think so; there are some swamps at the top of the creek, but they are very shallow.

Nature of strata.

2393. Have you any idea as to the nature of the strata below the bottom of the well to which you have referred? No, because we could not get through the sand drift in which we found the water.

Cost of sinking wells.

2394. What was the cost of sinking the wells? We did the work ourselves, but I would not undertake to

to sink a well and provide the timber for less than from 30s. to 35s. a foot. We have to get the timber from Narrandera and Deniliquin. Mr. Evan Jones. 15 Nov., 1884.

2395. What is the ordinary level of the water in the wells? In the deepest well the water is 30 feet high. The level in all the wells is about the same. The well from which I am pumping now is within 4 feet of what it used to be when there was water in the creek. I think that these wells are supplied by an undercurrent from the Murrumbidgee. The undercurrent of the Yanko Creek has been of more value to us than the surface water for the last four years. Level in wells.

Mr. Michael Curtin called in and examined:—

2396. *Chairman.*] Where do you reside? At Jerilderie. Mr. M. Curtin. 15 Nov., 1884.

2397. Can you give us any information with reference to the Yanko Creek? I have known the creek for twenty years; for the last five or six years there has scarcely been any running water in it at all.

2398. Can you give us any information in reference to the Billabong? I know that the bed of the Billabong is filling up year by year. Billabong.

2399. Have you ever heard the selectors on the creek complain of the want of running water? Yes, there is a general complaint from them. Want of running water.

2400. Do you think that, if the Government were to carry out works which would ensure a regular supply of water in the creek, the residents would be prepared to pay a rate equal to the interest on the money spent? From remarks which I have heard them make I should think so; I have heard several express themselves in favour of paying such a rate. Payment of water rate.

2401. Would you be in favour of a local Trust being empowered to carry out the work? Yes, I think the work would be better done by a Trust than by the Government, because the local people know the country very well. Local Trust.

2402. Does the Yanko Creek discharge into the Billabong? Yes, about 25 miles from here. Junction of Yanko and Billabong.

2403. Has the water ever run right through into the Billabong from the Yanko? Yes, several times.

2404. Do you know where the outlet of the Billabong is? Yes; it discharges into the Edwards, near Moulamein, but the Billabong is gradually filling up—there is not sufficient water to carry the silt away. Outlet of Billabong.

2405. Is there very much water in the Billabong at the present time? Very little—it is a chain of water-holes. It was the same last year. The water has not run through at all this season. Water in Billabong.

2406. *Mr. Gipps.*] Supposing a good supply of water were run into the Billabong, what number of people would be benefited by it? I suppose that the water would go all the way to Moulamein, therefore the people all the way down would be benefited. There are selectors all the way along the Billabong. Supply of water in Billabong.

2407. Do you think that if the water were diverted from the Murray into the Billabong it would be of any service to the settlers? I think that it would be better to divert the water from the Murrumbidgee, because then the selectors on the Colombo would get the benefit of it. Diversion from the Murray.

2408. From what source does Jerilderie derive its water supply? From the Billabong Creek. Sometimes the water comes from the Murrumbidgee into the Colombo and into the Billabong. There has been very little water in the township during the last two or three years. There are two dams near the township in which there is no water now. We have to cart water about 2 or 3 miles from a water-hole, in which very often there are dead horses and cattle. Jerilderie water supply. Carting water.

2409. Is not the health of the population affected by the use of such water? Such does not seem to be the case; but the majority of the people have underground tanks, from which they get a supply of water for domestic purposes. Poor people who have not tanks have to use the water from the creek. Underground tanks.

2410. At what height would the Yanko Creek have to run before it would flow into the Billabong? I do not think the water has flowed into the Billabong from the Yanko for years—it has been kept back by the dams. To flow over the dams the water would have to be 20 feet high. The dams throw the water back into blind creeks. The water must run clean over the dams before the people below can get it. Water from Yanko running into Billabong.

2411. *Mr. M'Mordie.*] Are the dams so high that they throw the water over the banks? I think so. I know that the settlers on the frontage of the Yanko have not had a drop of water this year. Dams.

2412. Is there any supply of water coming down the Billabong Creek from its own head? Sometimes, but for two or three years it has not come down; it did not come down last year; I think it is at least two or three years since it came down. Billabong head waters.

2413. Was there any considerable supply when the water came down last time? There was, but we had no dams here to intercept it. Last water supply.

2414. Does the water flow in the Billabong for any length of time? In dry seasons it does not, but I have known it to flow continuously for twelve months. Intermittent flow in Billabong.

Mr. Matthew L. Ashe, Manager of the Bank of New South Wales, Jerilderie, called in and examined:—

2415. *Chairman.*] Have you resided here for any length of time? About three years. Mr. M. L. Ashe. 15 Nov., 1884.

2416. What opportunities have you had for gaining information on the question of bringing water by the Yanko Creek? All that I know about it I have gained from the residents on the creeks. From what I have heard, I have no doubt that the proposed cutting would do an immense amount of good; I believe, from what I have been told, that it would give a supply of water through the Yanko and Colombo to the Billabong, and that embraces a considerable extent of country.

2417. Suppose the proposed work were carried out, do you think the people residing on the creeks would offer any objection to the payment of a rate sufficient to cover the interest on the expenditure? I do not think so. Payment of water rate.

2418. Do you think it would be advisable to entrust the work to a local body? The question of a Trust has not been mooted here, but I believe that if a Trust were appointed, the work would be done satisfactorily. Local Trust.

2419. Do you know anything about the dams on the creeks preventing the water from coming down? I have heard that the dams on the Yarrabee Station prevent the water from coming down, but I have not seen these dams. Dams.

2420. Do you not think it would be advisable to appoint a Trust to regulate the supply of water, so as to prevent one man from getting more than his fair share of water? The difficulty would be to get disinterested and practical men. If the Government undertook to regulate the supply, they would no doubt send practical and disinterested men. Supply of water regulated by Trust.

Mr. M. L. Ashe. 15 Nov., 1884.

2421. Have you had any experience of Water Trusts elsewhere? When I was in Mansfield, in Victoria, there was an agitation for the formation of a Water Trust there. I am aware that Trusts have been formed in Victoria, and it is said that they have done good work. The only difficulty about the formation of Trusts is, that you may not always get disinterested men. If we had a municipality here, that difficulty would be overcome to a certain extent.

Trusts in Victoria.

Run of water in Billabong.

2422. Do you know how often the Billabong runs? I have been given to understand that it has run through every year during the last ten years; I know that it has run through during the last two years.

2423. Did it run through last year? Yes.

2424. From what source? I believe from its head, and not from the Yanko.

2425. You are quite sure that the Billabong ran through Jerilderie last year? Yes; I suppose it was 10 feet deep opposite the township last year, but that was only for a few days.

Dams on Billabong.

2426. Are there any dams on the Billabong which conserve the water? Yes, and they were filled last year. The Coree dam was cut away by the people residing below it.

Destruction of dams.

2427. *Mr. Donkin.*] Do you think it likely that the people will cut away the dams which have been constructed for the supply of the township? I have been given to understand that it would not be lawful for the people to cut the dams, as they are not above summer level.

2428. Why did the people cut the Coree dam? They said that it threw the water out of the creek into another creek 4 or 5 miles away. I do not think that any objection would be offered by any one to the construction of overshot dams on the creek.

Supply of Billabong from Murray.

2429. *Mr. M'Mordie.*] Do not you think that a better supply could be got into the Billabong Creek from the Murray than from the Murrumbidgee? I do not see how you can get any connection between the Billabong and the Murray. If there is a sufficient supply in the Murrumbidgee I should decidedly think that it would be better to get the water from that river, but I have never heard any one suggest that the water of the Murray should be diverted into the Billabong.

Wool-washing.

2430. *Mr. Gipps.*] Is any wool-washing done on the banks of the Billabong? Yes, in the tributaries, but not on the main channel.

Natural supply of Billabong.

2431. *Mr. Murray.*] In an ordinarily good season the Billabong would be supplied from its natural source, without any water coming in from the Yanko? Yes, but only for a short time; it would perhaps run for four weeks during the year.

Ordinary flood-level.

2432. *Mr. Franklin.*] What is the ordinary flood-level—is it higher than the overshot dams near the township? Yes.

Length of Billabong.

2433. What is the length of the Billabong from here to its outlet? About 200 miles.

Floods.

2434. Are the floods continuous? No; the water runs away very quickly. I have seen the water over the fence close to the bridge, and the next morning it would be below it; perhaps on the following day it would be gone altogether.

Overshot dams.

2435. If there were a series of overshot dams on the creek, would they conserve a permanent supply of water? Yes.

2436. *Mr. M'Mordie.*] There would be no use in sending a supply from the Murrumbidgee once or twice a year? Only in the event of dams being constructed, because the creek dries up very rapidly.

Mr. James D. Rankin, auctioneer, Jerilderie, called in and examined:—

Mr. J. D. Rankin. 15 Nov., 1884.

2437. *Chairman.*] Have you been long in the district? About eight years.

2438. Do you know how often the water from the Yanko has run through into the Billabong? It has not run through since 1879—then the Yanko was running a banker.

Yanko and Billabong Creeks.

2439. What do you think is the reason of the water not running through more frequently? I think it is caused by the dams on the upper part of the Yanko. If the flood from the Murrumbidgee into the Yanko is not continuous the dams intercept the water, and then when the river subsides, a large quantity of the water flows back into it. I have been told that some of the dams are as high as from 15 feet to 18 feet. The water must have been thrown over the banks of the Yanko in the last flood. I am decidedly of opinion that all the dams should be overshot dams.

Dams.

Water rate.

2440. Do you think that the people on the creek would be willing to pay a rate equal to the interest on the cost of a work which would provide them with a supply of water once or twice a year? From what I have heard, I do not think they would offer the least objection to it.

Irrigation.

2441. Do you think that if there were a constant supply of water in the Yanko and Colombo Creeks irrigation would be carried on to any extent? The only person I have heard talk about irrigating is Mr. Killen, and I have no doubt that if one man were to do it, and the work were successful, others would follow his example.

Flow in the Billabong.

2442. Has the Billabong run through once a year during the last ten years? Yes, until this year.

Better supply in Billabong.

2443. Can you suggest any means by which a better supply of water could be obtained on the Billabong? I think that if there were a good supply on the Colombo and Yanko Creeks, a good supply in the Billabong would be ensured.

Dams.

2444. Are there any extensive dams on the Billabong which divert the water on to the plains? There may be one or two. There are a few below here, about which the people have been complaining.

Wells.

2445. Have you had any experience of well-sinking in the district? I know that a large number of wells have been sunk, varying in depth from 40 to 120 feet, and that in all cases water has been obtained.

Water-level in wells.

2446. Do you know whether the water in the wells rises to any particular level? I do not think there is any uniform level. The supply in the wells varies; there is a well at the railway station, the depth of which is 105 feet. There is about 8 feet of water in it.

Supply in wells.

2447. Generally speaking, is there a good supply of water in the wells? There is. It is a very rare thing to hear of a well being sunk without water being obtained on these plains.

Supply of the Billabong in 1879.

2448. *Mr. Murray.*] Did the bulk of the supply in the Billabong in 1879 come from the Yanko and Colombo Creeks, or from the natural source of the Billabong? It was a wet season generally, and a good deal of the water must have come from the Colombo and Yanko Creeks, as they were both running.

Mr. J. D. Rankin. 15 Nov., 1884.

2449. Do you think that any water came from these creeks into the Billabong last year? No, I think not. I believe there was an exceptionally heavy fall of rain near the source of the Billabong, and that the water which we had came from that source. Source of the Billabong.

2450. Do you know of any feasible plan of diverting the Murray waters into the Billabong? It might be done by canal, as I believe that the level of the Billabong is considerably below that of the Murray. Diversion of Murray waters.

Mr. Edward Killen, grazier, called in and examined:—

Mr. E. Killen. 15 Nov., 1884.

2451. *Chairman.*] Have you had any lengthened experience in the Jerilderie district? I have been here about nine years.

2452. Can you give us any information as to the time which it takes, under different circumstances, for the creeks to flow through at the present time? No.

2453. Can you suggest any means by which the rapidity of the flow in the creeks can be accelerated? If the Yanko Creek were cleared of snags, and the cutting into the Murrumbidgee made sufficiently large, I have no doubt that the flow of water would be increased. Acceleration of flow in the creeks.

2454. Do you think that it would be sufficient for the requirements of the people on the creeks if water were run through once a year for certain? Yes; I think that it would give them a supply from one year to another; it would supply the pressing wants of stock, but would not admit of irrigation being done. Frequency of supply.

2455. Do you think that if the Yanko were to run through whenever there was a rise above 5 or 6 feet in the Murrumbidgee that irrigation would be carried on to any considerable extent? I think that irrigation would be carried on to a considerable extent on the Yanko and the Billabong if there were sufficient water. Irrigation.

2456. Do you think that, in that case, the people who availed themselves of the advantage would be prepared to pay a rate which would cover the interest on the outlay? I think that they would, but I have no doubt that a great number would hold the opinion which I do,—that as the Government have received such a large amount of revenue from the sale of lands here, they ought to make provision for the supply of water to us. The expenditure would be small in comparison with the land revenue which the Government have derived from the district. At the same time I believe that the people would pay a fair rate rather than be in want of water. I think that it would be unreasonable for the Government to ask for a rate under the circumstances. The expenditure of the paltry sum of £7,000 or £8,000 would do all that we want to have done. Water rate. Water supply secured by Government.

2457. Can you give us any idea as to the amount of irrigation which would be done? No; I had intended to irrigate from 50 to 100 acres myself, but I would not undertake to do so with the uncertain supply of water which we have at present. Irrigation.

2458. Can you tell us how often the Billabong has run through here? I live on the banks of it, and I know that it has run through every year until this year. Supply in the Billabong.

2459. But we have been told in evidence that it did not run through last year? I know that it ran through here for at least six weeks last year.

2460. Do you think that the dams in any of the creeks are a hindrance to the water running through? I do not think that they are. I have not seen the Yarrabee dams, and it is quite possible that they throw back into the Murrumbidgee water which would come here if it had a free flow. Effect of dams.

2461. You have no objection to overshot dams being constructed? No man of common sense would object to them. Overshot dams.

2462. Do you think that a series of dams on the creeks would conserve a large quantity of water, which would benefit the district and affect the climate? It would be an immense benefit to the district, and I believe that it would affect the rainfall to a slight degree. Conservation by series of dams.

2463. *Mr. Gipps.*] Do not you think that it would be advisable to have sluice-gates in the dams, in order to allow the dams furthest from the source to be filled first and so on to the source? I think that that is a good idea, but it would be attended with considerable expense. It would prevent grumbling on the part of the people on the lower parts of the creeks, and it would prevent the water from returning to the river. Sluice-gates.

2464. Do you know of any springs in the district? No.

2465. Do you think that the necessary works would be carried out better by a local Trust than by the Government? I should be in favour of the Government doing the work. Trust.

2466. *Mr. Franklin.*] Are there many people who would be benefited by the improvement of the Yanko inlet? There are a large number of residents on the Yanko and the Billabong. Yanko inlet improvement.

2467. What makes you think that the necessary works may be constructed for £7,000 or £8,000? I have been told that amount would make the proposed cutting.

2468. As this is only a small portion of the Colony in which such works are needed, what real excuse is there for the people not paying a reasonable rate—such a rate as would cover the interest on the cost of the work? I do not think any one would object to doing so—I believe that all the landowners on the creeks would willingly pay a portion of the expense. Water rate.

2469. You must bear in mind that, according to your estimate of the cost of the work, £300 a year would pay the interest? I raise no objection as to the amount. My contention is that, as the Government have derived such a large amount of revenue from the sale of land in the district, they ought to bear the whole of the expense. Revenue from land sale.

2470. *Mr. Murray.*] Although you are in favour of the work being done by the Government, do not you think that it would be a good thing to appoint local Trusts to regulate the supply of water? I dare say that it would be. Local Trusts.

2471. Whence do you derive your supply of water? Principally from the Billabong. There has been a dam at my place for eight years; there has always been plenty of water in it, and no attempt has been made to cut it away. Supply of water from Billabong.

2472. From what source do the majority of the people derive their supply of water? From holes in the creeks.

2473. Has there been any loss of stock on the Billabong this season? Stock will bog in some places in the creek at the present time, and we are all shifting the stock for want of grass as well as of water. Loss of stock.

THURSDAY,

THURSDAY, 20 *NOVEMBER*, 1884.

At Sydney.

Present:—

MR. BARTON, M.P., | MR. GIPPS, C.E.,
MR. DONKIN, J.P., | MR. LYNE, M.P.,
MR. FRANKLIN, C.E., | MR. MURRAY, M.P.,
MR. M'MORDIE, B.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. W. B. Henderson further examined:—

Mr. W. B. Henderson. 20 Nov., 1884.

2474. *President.*] What is the name of the other well to which you referred in your last evidence? Bore D, 7 miles beyond the Goonery well.

2475. What further information have you obtained since you last gave evidence? I have struck water in another bore.

Water in a bore.

2476. In that particular bore? No, we have been stopped on that line, owing to the drought.

2477. Did you go on sinking after you had got water? Not far—the rock was too dense for steel cutters.

Quantity of water.

2478. What quantity of water did you get? 4,320 gallons a day.

2479. Can they raise that to the surface? It is flowing over the surface.

2480. Then why should there be any want of water? I refer to that line further ahead.

2481. You are not going further? No; but I believe we shall get an immense supply in that well. The object for which we started has been attained.

Section.

2482. Have you a section of that well here? I have.

Well beyond Goonery.

2483. Can you give the Commission any further information about the well 7 miles beyond the Goonery? The only information I can give is that we have gauged the water, and the quantity obtained is 4,320 gallons a day, flowing 3 feet over the surface. It has been flowing for some time. This is the last water from the lowest level.

2484. And have you given up sinking in that well, or are you going further? We have given up for the present. I was thinking of recommending a diamond drill there, as the rock is hard.

Nature of rock.

2485. Do you know the nature of the rock? Yes, it is cretaceous mud rock.

Tank.

2486. Are you sinking further out? No. We went out and made a tank, and had to have water carted to it a distance of 18 miles. The tank was intended for the domestic use of the party. Since we made the tank there has been no rain to run into it, and we have had to give up.

Cased bore.

2487. *Mr. Franklin.*] Is that an open bore or a cased one? It is cased for some 357 feet.

Carrying of water.

2488. *Mr. Barton.*] What was the object of sinking so near, instead of going further into the Goonery Plains? It was considered that we should not be able to carry water further; the road is very heavy. We had a team of eight horses, and it was found they would not be able to carry the water much further. The original intention was to go 15 miles away. An inspector was sent out, and he thought that the distance would be 10 miles, instead of only 7 miles. It would take two other points between Bore D and the Paroo to open up the road. I got a telegram recently to say that some rain had fallen towards the 75-mile site. It is the intention to put bores down at the 75 and 95-mile posts, should rain come to admit work, and so open this route.

Wells about Walgett.

2489. *President.*] Are you continuing to sink wells in any other places? Yes, about 40 miles from Walgett is one point.

2490. Since you last gave evidence have you struck any fresh water near Walgett? Yes.

Position.

2491. Describe the position? It is about 5 miles from the former bore.

2492. North, south, east, or west? West.

2493. Can you point it out on the map? No; the owner of the station has promised to get me information as to the exact spot.

2494. What is the object of sinking for water in that neighbourhood? There is not a drop of fresh water near there.

Payment for use of machine.

2495. At whose instance is it done? That of Mr. Capel, the squatter who owns the station. He pays the Department so much a week for the use of the machine.

2496. Under your guidance? Yes, the Department sends out a machine and one man in charge. The hirer pays for use of machine and finds the other labour required.

2497. It is not a stock route? No.

Supply.

2498. What is the supply of water in that well? They cannot gauge the supply with available appliances, as after they lower the water to a certain depth it stands at one level.

2499. Is it an artesian well? No, it rises to within 78 feet of the surface.

Salt water.

2500. Did you strike any water above that? Yes, salt water.

Depth from surface.

2501. At what distance from the surface? Between 70 and 80 feet, then at 30 feet below that, and again at about a depth of 180.

Salt water.

2502. Is this a tube well? Yes. We have also struck an immense supply of salt water between Callarandrie and Angledool since my last examination.

2503. You say this is salt water? Yes.

Depth.

2504. At what depth? We have struck a very strong supply at a depth of 166 feet.

2505. Is that in a tube well? Yes.

Rise.

2506. Does it rise to the surface? No; it rises close to the surface.

2507. Do I understand you to say that it is so salt that it cannot be used for stock? It is as salt as the sea.

Crust of cemented gravel.

2508. *Mr. Barton.*] Is it your intention to go through it? Yes; they are on a very hard crust of cemented gravel at present.

Nature of country.

2509. *President.*] What is the nature of the country where you found the water? I do not think it is cretaceous.

Water-worn gravel.

2510. Is it drift? It is gravel, drift, and clays. I think there is fresh water underneath. The gravel there is more water-worn than in the borings west of Bourke.

Wells between Wilcannia and Silverton.

2511. Are those the only two wells that you have any further information about? We are sinking between Wilcannia and Silverton, and since I was here last they have struck brackish water. On going a little deeper the water is found to improve slightly. A great deal of limestone is met with. This point is between Wilcannia and Silverton, about 20 miles west of Wilcannia.

2512.

Mr. W. B. Henderson.

20 Nov., 1884.

2512. Do you find as a rule that, throughout New South Wales where you have been sinking, you strike salt water above the fresh? Yes.

2513. Then the supply of fresh water that you strike below the salt water is in most cases artesian? Yes. One thing noticeable about it is that each stratum of water struck has its own particular level. If we strike the water (say) at 80 feet in a well it rises to a certain point; if we strike water in another stratum below that, it does not rise to the same point. Fresh artesian water below salt water.

2514. Then each water is distinct from the other? Generally. With very few exceptions I find that each layer has its distinct point of level. Sometimes it does not rise so high as the water struck above it. As a rule, the deeper the water is struck the higher it rises. Distinct point of level of water strata.

2515. Have you any further information that you particularly desire to give to the Commission? None except as to the supply of water which I have observed in the high lands. When connected with mining I used to pay particular attention to it all over the Colonies. I have taken notes of my observations for over twenty years. Supply of water in the high lands.

2516. What observations have you made? In working the mines on the old basaltic formation in the Colonies I have found in several instances the water so strong in those old river-beds that there was no chance of overcoming it except by tunnelling. In instances I have followed the water down from 100 feet to 200 feet under existing watercourses. Water in old river-beds in the basaltic formation.

2517. What deduction do you make from that? That these are old river-beds starting all along the dividing range, covered by basalt, and once they take a trend out to the west they are gorged with an almost unlimited supply of water, and are covered over with this formation much deeper than the present rivers and creeks. Unlimited supply.

2518. Can you give us any information as to these cases? Yes, there is one case at Tumberumba where the basalt crops out covering a defined lead commencing at a point known as Surface Hill. Out-crop of basalt at Tumberumba.

2519. From towards Adelong? Yes. I was superintending workings there ten years ago, and followed that lead down towards and below Tumberumba. A tunnel was put in above Tumberumba to tap the lead from the level of the existing creek. Some tunnels were also put in below Tumberumba. The tunnel furthermost up the creek referred to, after being down some 200 feet, came on the lignite, dipping at an angle of 40 degrees into the hill directly under the run of basalt, which run averaged about 300 feet in width. The water tapped here below the lignite was so strong that it was considered impossible to follow the dip downward even with powerful machinery, so the work was abandoned. The tunnels below the township, from level of existing creek, came on the lignite fast dipping, water also strong—too strong to follow downwards. The water continued to flow from the tunnel deepest tapped strong and steadily, and was so years after, on my last seeing it, without any apparent diminution. Water tapped below the lignite.

2520. That was where you found the lignite? Yes, under it the water flows strongest.

2521. How far is that from the Tumberumba township? The tunnel referred to is about 1½ mile.

2522. Up the creek? Yes.

2523. Does the water come out of that tunnel into the creek? Yes. I traced this lead down below Tumberumba.

2524. Still in the hill? Yes. The existing creek crosses the basalt, and it is on the top of the basalt. A little further on it trends towards the Murray, and disappears altogether. There is a dip of 350 feet in about 10 miles. Creek on top of basalt.

2525. Where you lose the basalt you lose also this flow of water? The present creek is on the top of the basalt, some distance below Tumberumba. Further down the basalt is covered out of view.

2526. You struck the water below the lignite above Tumberumba? Yes. Water below the lignite.

2527. You also struck it below the lignite in the same formation below Tumberumba? No, I was above the lignite there. I proved further down the creek the dip of the basalt.

2528. But you could prove the water? The water lodges under the lignite all the time. The lignite follows the old creek or river-bed, and is bound to be full of water. Old river-bed.

2529. You struck the water above Tumberumba in a certain formation—you also struck that formation below Tumberumba? Yes, the top of it.

2530. Is there water below that? Yes.

2531. This formation dips under the Tumberumba Creek; or rather, the creek goes through a gap? Yes. Dip of formation.

2532. And dips so rapidly that you lose it entirely in its course towards the Murray? Yes.

2533. Your theory is that that formation still continues? Yes.

2534. And the lignite also? Yes.

2535. But this underground watercourse is tending towards the centre of the Colony? I thought, in following it first, that it was tending due east, and I followed it down, but I found that it turned right round to the south, then to the south-west. Direction of the old river-beds.

2536. That is towards the centre of the Colony? Yes. I could give ten or twelve cases, and in every case these old river-beds trend westward. In examining the Bingera district some six weeks ago I had occasion to examine one of these old river-beds, basalt-capped, containing diamond-bearing drifts under the basalt. I crossed it at different points extending over 30 miles in length. Old river-bed in Bingera district.

2537. What width is it? From a quarter of a mile—even less in some places—to, at the most, 1½ mile; that is the outside—the lip, but I should think that the centre or deepest part would be about 300 yards. Width.

I took the measure from Bingera of the present river-bed, the Gwydir, a very big river. By aneroid measurement, from the top of the basalt lead nearly opposite Bingera, I found that the height was 1,010 feet over the Gwydir. That is the highest basaltic peak. It goes due west, and disappears under the said river, being lost sight of altogether. The diamond drift is comparatively high up in the range. I followed the line of basalt down, and found one shaft sunk over 200 feet, being considerably under the deepest level of the existing creek. At this point the dip of rock from bottom of shaft trended still deeper. Water was met with, and work was suspended. Lignite was passed through in sinking. A miner named Cross put down the shaft and supplied me with the information. I observed that the wash obtained from bottom of shaft was highly water-worn. That is a proof that the old river-bed exists under the existing creek course in that instance. A few days after I inspected another basalt lead, about 10 miles to the west of Bingera. The one first referred to is about 10 miles to the east. Cross, the miner referred to, had been prospecting the former lead east of Bingera. I also found him at work prospecting the second lead west, with somewhat similar results. He was prospecting on the flanks of a high basalt-capped hill—a defined old river-bed. Had sunk shaft after shaft under the level of existing watercourses, and found the wash dipping into and under the hill in every case. At this point he had come across a The Gwydir. Height of basalt lead. The diamond drift. Lignite. Water-worn wash. Another basalt bed. Old river-bed.

Mr. W. B. Henderson. 20 Nov., 1884.

nice prospect of heavy water-worn gold, which I examined, obtained from highly water-worn gravel-wash. Lignite and water in abundance existed in this case also. Our conclusions agreed, viz., that these two leads take their rise from the high lands on the dividing range in the New England district.

2538. *Mr. Murray.*] What hill is that? It is in a direct line with Bingera and Inverell. There is, I understand, tin not far from there. Mr. Cross informed me that he had prospected, he thought, on this same lead for nearly 100 miles towards its upper end. I had observed the existence of such a lead trending west, at Uralla, years ago.

2539. *President.*] Are they both full of water? Yes; and there is no chance of the miners working them except on the high ground further up in the mountains.

Old river-beds in Victoria.

2540. Have you any other cases? Yes; there is another case in Victoria to which I may as well refer. I happened to be the lessee of the Seven Hills Estate in 1861. The estate consists of 7,000 acres, and, as is well known, contains some rich gold mines. I have ridden over the plains there, through a mass of basalt. For 20 or 30 miles it is comparatively flat country. In those days I had no idea that we were sleeping over gold, or I should not have left there to look for gold elsewhere. I am acquainted with the ground held by the Madame Berry's Claim. The diamond drill was set to work in this district in 1877.

Birch's Creek.

Birch's Creek is the largest in the immediate district. As nearly as I can estimate, Madame Berry's Claim is about 250 feet below the level of Birch's Creek. The lead is making directly across the creek. They have traced it making at right angles to it, and with all the machinery they can supply the miners

Basalt formation.

are nearly forced out with water. It is a basalt formation, and a notable point in connection with the matter is that the lead has started from the high ranges towards Ballarat, just as those leads described start from the highest ranges with us. There is so much water that all their engineering appliances can hardly cope with it. I know that this basalt formation continues through Smeaton Plains at least 40 miles, but where it goes to I do not know. That is trending about north-west also.

Other instances in N.S.W.

2541. Do you know of other instances in New South Wales? Yes, there is the Gulgong one. Hanging Rock, near Nundle, is the starting-point of another. I have crossed those basalt-covered lands several

Ben Lomond.

times at several places. There is another starting from Ben Lomond, the highest point in New England.

2542. *Mr. Franklin.*] On the western shed? Yes. Another well-defined basalt lead further north—one

Vegetable Creek.

which I have worked upon a great deal—starts from the table-land near Vegetable Creek. That trends towards Inverell. I have worked on it, starting on the high ground and down to and below the existing creek. I pointed out where this lead was trending to when I went over the ground ten years ago. There

Caroola. McIntyre River.

is another lead which starts near Caroola, and they are working that, making for below the level of the McIntyre River.

Direction and inclination of the leads.

2543. *President.*] Is that leading west also? It is. They all trend toward the west, some going a little northward. The inclination of the leads is to the north-west; the existing rivers go more to the south-west.

Cases west from Sydney.

2544. Do you know cases out west from Sydney? Yes, Gulgong, near Mudgee, to which I have referred, a deep lead of basalt formation, with water very plentiful under.

2545. Were you ever at Hill End? Yes, I know almost every mine at Hill End.

Rock formation at Hill End.

2546. Is there anything similar there? No; it is a high-lying primitive rock formation. The outline of the trap rocks bears nearly right along the main range. Large deposits exist at Kiandra, Canoblas, Nundle, Uralla, Ben Lomond, and Mole Table Land.

2547. Have you any plans showing those leads? No, but I might be able to sketch them out. I had plans accompanying reports when I was employed by private people. I supplied over 300 such reports, but I do not suppose I could lay my hands on them now.

Plans.

2548. Can you give us information as to where we are likely to get plans, if we are desirous of following out these leads and placing them on paper? Looking at the geological map, I should think it is no

Flying surveys.

assistance to trace through leads. It would be very easy for the Commission to take flying surveys. I could obtain certain reliable information by writing to miners I know, and asking them to fill up the gaps unknown to me along such leads.

2549. Could you take a skeleton map of the Colony and place these leads approximately? Yes, but there

Special geological surveys.

are others not sufficiently known to me; the work refers to a large scope of territory, and I think should have special geological surveys made for this purpose alone.

Underground streams in the basalt formation.

2550. To sum up the whole matter: I suppose your opinion is that there are large underground streams of water running in the basalt formation; that these start from the main ranges which run north and south, and go in a westerly or north-westerly direction? Precisely so. I have travelled on and adjacent to the high lands right through Victoria and New South Wales on to the Darling Downs in Queensland ranges. I have mined underground in many of such ranges and paid close attention to my work. All bear out the same theory.

Artesian water in western plains.

2551. You are now sinking for water in the western plains of the Colony—do you find it artesian in many instances? Yes.

Source of artesian water.

2552. Is it your opinion that artesian water comes generally from the source you have referred to to-day? Yes, and I am convinced that there is such a large quantity of water existing that no one has any conception of the quantity that will be got by searching for it, within the next ten years. If we prospected to the head of the leads which I have been describing, we should find immense quantities of water.

2553. But you cannot have more than falls from the clouds? I think so. The matter has been very

Two different underground streams.

little looked into by scientific men. I have struck two streams of water underground within 10 feet, differing entirely in trend, quality, and temperature.

2554. What I mean is that the original source is rain? Yes, but water is taken into the earth in one

The action of the earth's crust on the water.

part of its surface, and thrown out in another by forces other than gravitation. The earth's crust acts like a steam pump or hydraulic ram, taking in the water in one place, compressing it into force, and thus throwing it out elsewhere. I believe that if we tap the primitive rocks in the interior, in certain instances,

Water in primitive rocks.

to say nothing of the old river-beds, such rocks will be found to give water other than that resulting from the local rainfall. I am sure of it, because I have proved it in practice.

Water from other parts of the globe.

2555. Have you a theory that water comes from other parts of the globe and makes its exit here? I decidedly think so, at least adjacent parts of the globe. I could not say how far the water comes. I have seen it stated on good authority that water has issued out of the earth's surface 500 miles away from where it originally fell in the shape of rain.

2556. I said that we must look to the rainfall in the first instance, but I understood you to say that we must

Mr. W. B. Henderson. 20 Nov., 1884.

must look to some other source? I would not say positively to force my opinion that water comes from a given line outside the Colony; but where does the water in cases of artesian hot springs come from, unless it is accounted for by the proximity of some volcano near by?—That is not so in all cases; water does not come from the immediate clouds, or from surface lines laid down or known to man.

Level of underground water.

2557. *Mr. Franklin.*] The water discharging through these leads I suppose is traced below the ordinary levels of the beds of rivers? Yes.

Interception and storage.

2558. Do you think it would be possible to intercept the water and store it in large bodies? Yes. I have worked under the surface of the earth in the several Colonies during a great part of my life, and my impression is that throughout Australia we shall yet find a very large number of artesian wells, because there is an outlet or escape. The water will, in my opinion from practical experience, be found to come up a certain distance and then escape; but there will be immense quantities of water to be got over large areas of Australia, at depths ranging from 40 to 80 feet. Water rising to such a level will be very easy got at by pumping it up. A return from South Australia, Victoria, and New South Wales, herewith in part handed in (*Appendix* O 1), shows that more than two-thirds of the bores put down have struck good water. In working out returns of water found in the Colony, I endeavour not to over-estimate the results obtained. I found, as a rule, that the water is the strongest when it is first struck. Sometimes pumping is kept up for a couple of days, then when it is finished the standard is ascertained and the return is given. We have obtained more fresh water in proportion than South Australia, and much more than Victoria. In looking for an explanation of this, I find that Victoria has the shallowest bores and South Australia has some of the deepest; but New South Wales has, on the average, the deepest, and it is the depth that has given us the largest proportion of fresh water. If, in Victoria, the wells or bores were made deeper no doubt the result would be more favourable. Some of the wells sunk under my supervision give salt water, but we are proving every day that the salt water is merely superficial. If we go to a medium depth, no doubt we shall get yet more good or fresh water. We ought, I think, to go to a depth of from 500 to 1,000 feet if fresh water is not obtainable sooner. I believe, however, in going down to a considerable depth to test the matter of primitive rocks. So far we have been lucky in getting water at shallow levels.

Immense quantities of water.

Returns of water found in the Colony.

Depth of bores.

Interception of permanent leads of water.

2559. If these permanent leads of water are intercepted at such places as Ben Lomond, would it not be best to store it on the slopes of the hills? Yes; the best course is to make it available for gravitation, and so to catch what is actually available first without allowing it to go to waste. A bird in the hand is worth two in the bush.

Ground for storage.

2560. Do you think we should find impermeable ground on the mountain slopes where we could store water? Yes; there are nice clays on the high lands which could always be depended upon in making excavations.

Sites for practical operations.

2561. With reference to the places you have pointed out, could we, without much difficulty, pick out sites for practical operations? Yes, easily. The more trouble people generally take with regard to the construction and cutting out of dams, the worse they are generally to combat with Nature's laws of force of penned-up water. I have had a great deal of experience with regard to dams. People, as a rule, dam creeks in the wrong places. If they would observe the provision that Nature has made, and make dams where there are side-way flats, it is there that the water will stand. If they dam the water in the confined precipitous situations everything goes.

Position of dams or creeks.

Boring at Warrigul.

2562. *Mr. Barton.*] Do you know anything of some experiments in boring which have been carried on by a Mr. Bignall at Warrigul? Yes, I supplied him with a list of things necessary to carry out that work.

2563. Do you know whether he has been successful? Yes, he has got water in the three bores which he has put down, but he had in instances to sink shafts. In the first case he sank the shaft to a certain distance, then bored. I retain a paper giving particulars of the boring. (*Appendix* O 2.)

Diamond drill.

2564. Is it the diamond drill that he has been using? Yes, but I converted the drill into a steel cutter as well. It could not have gone to work without water, but he had water in a shaft which he had already sunk. I supplied him with a list of the necessary tools and tubing, and made the undertaking a success.

Cost of machines.

2565. *Mr. Murray.*] I should like to arrive at the cost of these machines. You say that Mr. Capel pays £5 a week for his water auger: are there many availing themselves of these augers? There are two out on hire now.

2566. How many augers have you? Eleven.

2567. Are they all at work? All except one.

2568. All working for the Government in dry country? Yes, on stock routes.

Particulars of cost.

2569. Have you made any calculation as to the cost per foot? Yes, I gave all the particulars of cost to the President to-day. (*Appendix* O 3.)

Result from hiring out augers.

2570. Have the augers as a rule been hired out at a loss to the Government or at a profit? The object of letting them out at £5 a week as per regulation is to make them pay all expenses. The foreman in charge who goes with the auger generally receives £3 10s. a week, and the balance is taken to be sufficient to cover the cost of wear and tear. The hirer supplies everything outside the plant as originally sent out. The man in charge who goes with the auger reports what he does every week to the Department.

Report on operation of the drills.

2571. Will you let us have a report as to the operation of these drills? I lay the annual report before the Commissioners, which will give the most minute information for the past year. I have taken great pains in putting the particulars on record, in order that some information might be afforded to the public, to whom the working of the diamond drills and augers seems to be a mystery hitherto. Some bores cost as low as 4s. 9d. a foot, but the average, as per report for the year 1883, is 10s. 3d. I have taken pains to provide the fullest information, so that the public shall know what a drill is, its cost, and how or for what it is worked.

Ballarat deep leads.

Rise of water in the shafts.

2572. *Mr. Gipps.*] Do you know anything of the Ballarat deep leads? Yes.

2573. Do you know the level to which the water rises in the shafts? I have handed in a statement which contains particulars. (*Appendix* L 7.) That statement will show that a few mines there have been pumping on the aggregate as much water as all Sydney. If that is on the top of the watersheds or dividing range of that Colony, it shows what we may expect in the west of the watersheds of this Colony. The "City of Ballarat" mine alone pumps something like three to five million gallons a day, and has been doing this for two and a half years without showing any sign of abatement. From a comparatively small area seven mines on the aggregate pump upwards of twenty million gallons per diem; one mine pumping for two and a half years with little or no signs of decrease.

Mr. W. B. Henderson. 20 Nov., 1884.

2574. Have you adopted any system in examining the subterranean waters of the interior? Yes, we test the water both when we strike it and at stated periods after it is struck—after a time.

Weekly tabulated reports.

2575. How far have you adopted any system of sinking your bores to show the inclination of your shaft? A tabulated report is filled in weekly by the foreman in charge that gives the strata, the depth of the water met with, and other particulars.

Direction of inclination.

2576. What system do you adopt in actual boring; do you make a bore, then go 7 or 8 miles away; or do you test the inclination by boring again a mile north, south, east, or west? Yes, we test the inclination, and when I get the different sections out I am able to see the direction of the inclination. By the aid of such sections I find that there is a dip of 60 feet to the mile from the Goonery Bore B 3, and the one (D) 7 miles further to the west.

Machinery.

2577. What machinery for boring do you recommend? The Australian water auger is by far the best. I herewith give in a statement of the results of the test of each class of borer named. (*Appendix* O 4.)

2578. Does that apply to soft strata and rocks? Not to rocks; nothing will touch the diamond drill for hard or dense rocks.

Diamond drill.

2579. What diamond drill do you recommend? Bullock makes one far superior to any that I have seen. It will work with half the diamond cost that any other requires—it will work a revolution in diamond drills.

Improvements in boring for water.

2580. Do you think you could suggest any improvement in the system of water-boring in the interior? Yes, by making the machines applicable to the different districts. For instance, where the carriage would be difficult, the machines should be light and made of steel. Where water is scarce diamond drills or steam power cannot be used. Where strata is medium hard to soft, steel cutters are best; but the most important of all is to have a practical knowledge of the many peculiar strata met with in inland Australia, and to be able to adopt and lay out the tools applicable to each stratum; without this knowledge (Australian) costly failures will ensue.

Corrosion in tubes.

2581. Do you find much corrosion in the tubes? No, not so far.

2582. Yet you go through this salt-water stratum? Yes, that does not seem to affect the tubing.

Pierce and Tiffin borers.

2583. Are you acquainted with the Pierce and Tiffin borers? Yes.

2584. Is there any similarity between them? They are almost exactly similar. If there is any difference, the Tiffin is an improvement on the Pierce borer.

Australian auger.

2585. You think that the Australian auger is the best? Its main parts of mechanism stand first for inland circumstances. It will do one fourth more work than one of the other augers, and doubtless at a less expense.

Shutting off salt water.

2586. What plan have you adopted for shutting off the salt water? When we desire to shut off the salt water, we drive the tubing down till we get to the rock or impervious clays. It is quite easy to combat with salt water.

Use of cement.

2587. Do you use any cement at all? Yes, we drop cement in between the two sized tubes in our telescopic order of boring, and it makes the joint as hard as a rock. In the event of no suitable clays being met with to drive the tubes down into, cement in cartridges is dropped into the bore, filling the hole up some feet; the drill-rods are then lowered, plugged in, and pressure is then applied and the tubes driven down, and thus behind and upwards in the tube a perfect water-tight bore is the result, boring being continued deeper after the cement sets, which, as a rule, does not require time so to interfere with work of boring going on. If you use tubing you are obliged to reduce your bore, but with cement you

Diamond drill.

can keep it one size—cementing on the method last described. The experience which one gets with diamond drills is the best. You cannot bore with a diamond drill unless you keep the bore perfectly water-tight. Experience with a diamond drill under steam, hydraulic water pressure in the bore, surpasses all that a man gets with the water augers—well-drilling machines. I have used brown paper, wheat, and linseed occasionally to keep the water out, but I never found anything equal to cement, which never fails. As a rule we lose the water five or six times every bore put down with the diamond drills, so the necessary experience to shut out or shut in water in boring is very soon learned.

Fresh water beneath salt water.

2588. *Mr. Barton.*] Have you ever found a large quantity of salt water without fresh water underneath? Not when boring was continued to any ordinary depth.

Cost of tubing.

2589. What is the cost of the tubing? The last tendered price was from 4s. a foot for 7 inches in diameter down to 10d. per foot, 2¾ inches in diameter. The best tubing is got from Europe, and it is remarkably cheap, the cost being about half that of equal gauge lining from America. The representative of a Company carrying on boring works in New Zealand, under the American principle, recently applied to me for some information as to this class of tubing known as artesian tubing. There is only one house that makes this special tube that I am aware of in Great Britain. There is another house in Germany that comes close to it in form, quality, and price.

Joints.

2590. *Mr. Franklin.*] Is the lap flush on the outside? You would not notice the joints. They are differently made from any other tubes I have seen. They are made by Messrs. A. and J. Stewart of Glasgow, who, I understand, are sending them all over the world. If it had not been for this class of tubes I should have been stuck fast with the boring in search of water inland in this Colony.

THURSDAY,

THURSDAY, 27 NOVEMBER, 1884.

Present:—

MR. BARTON, M.P.,
MR. DONKIN, J.P.,
MR. FRANKLIN, C.E.,
MR. GIPPS, C.E.,
MR. LYNE, M.P.,
MR. M'MORDIE, B.E., C.E.,
MR. R. L. MURRAY, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Cornelius Haylock called in and examined:—

Mr. C. Haylock. 27 Nov., 1884.

2591. *President.*] You are a licensed surveyor? I am.
2592. In what district? I have been in charge of parts of the Cooma District for about seventeen years.
2593. Have you had charge of work in any other parts of the Colony? No; I have worked in other parts of the Colony, but I have not had charge.
2594. In what parts? I was at Grafton a little while.
Murrumbidgee and Snowy Rivers.
2595. Can you give us your opinion in reference to the country at the head of the Murrumbidgee and the Snowy Rivers? I can.
2596. Will you tell us what you know about those places? I was employed to survey the boundaries of the Tantangara Run some years ago. At one point of it, where the eastern boundary of Tantangara strikes the Murrumbidgee River, there is a remarkable gap. It strikes me that a reservoir might be formed there. I hand in a tracing of the spot; it is at the point marked A on the tracing. (*Appendix* P.)
Remarkable gap.
Unsettled state of country.
2597. *Mr. Donkin.*] Is there any township near the place? No. At the time of the survey no measurements for sale or alienation of land had been made there. There is a selection of 600 acres marked on the tracing, and there are pre-emptive leases, but the country was then in an unsettled state, no alienations of land having taken place.
Position.
2598. What is the general position of the locality from Queanbeyan or Cooma? It is to the north-east of Kiandra. The gorge is a cut through what appears to be an even ridge.
Reservoir.
2599. *President.*] And you consider that a reservoir could be built to store an immense quantity of water? It is some years since I was there, but it struck me at the time that a large area of country might be put under water.
Altitude.
2600. Can you give us any idea of the altitude? I cannot form an opinion; but it may be readily determined approximately by the use of the aneroid barometer.
Area.
2601. Have you any idea of the number of miles? I should say that the area would be 10 miles square—varying from 10 square miles to 100 square miles, depending on the height of the dam.
Depth.
2602. And about what depth? It would be very difficult to say, because I have lost the exact recollection of the height of the ridge.
2603. *Mr. M'Mordie.*] Do you mean 10 square miles or 10 miles square? I mean 10 square miles.
2604. *Mr. Donkin.*] What is the depth, roughly speaking? I think it is about 100 feet. I should not like to hazard a guess.
Nature of country.
2605. What kind of country would be covered? Judging from its appearance it has at some time been under water. The river has gradually cut its way through the rock, and by degrees has formed the channel of the Murrumbidgee.
Inland sea.
2606. *President.*] Has there been a lake? A sort of lake or inland sea, I should say, at some former time.
Quality of land.
2607. Is it good or inferior land? It is tolerably good land.
Snow.
2608. I suppose it is covered with snow in the winter? Yes, to a depth in some seasons, I believe, of 6 or 8 feet.
Height.
2609. Do you know the height? I do not; I was on the point of going up with the barometer when I was called to Sydney by telegram.
Snowy River.
2610. Have you been to the head of the Snowy River? I have not been to the head of the Snowy River, but I know it at a point at and a little above its junction with the Eucumbene.
Eucumbene River.
2611. Have you been further up the Eucumbene or Snowy River? Considerably further up the Eucumbene, but not further up the Snowy River.
Width and depth of Eucumbene River. Good stream.
2612. What size is the river at the point of junction—of what depth is the bed? It varies from 2 to 3 chains across. It is a very dangerous river to cross. There is a solid rocky bottom with crevices, into which horses are apt to get their feet. The water comes up about half way between the girth and saddle flap. There is a quantity of water at a certain season, but at all times there is a good stream running in the Snowy River.
Velocity.
2613. *Mr. Franklin.*] What is the velocity? When I was working on the Snowy River at Buckley's Crossing, I estimated that with a very slight fresh the river ran about 4 miles an hour.
Dividing ridge.
2614. *President.*] Have you been along the ridge above Cooma dividing the Snowy River from the watershed of the Murrumbidgee? I know it well.
Levels.
2615. Have you ever taken levels there? I have.
2616. Have you taken any levels at the junction of the Snowy River and the Eucumbene? No; I have taken them at the top of the range and at Buckley's Crossing on the Snowy. I have them in Sydney, but have not brought them with me now.
Nature of country.
2617. What is the nature of the country between the junction of the Snowy River and the Eucumbene and the Dividing Range? Hilly.
Varney's Range.
2618. Is it very rugged? Not very rugged. The main road passes over what is known as Varney's Range. Whether you could avoid it or not I cannot say, but I think it might be done by a detour.
Diversion of Snowy River water.
2619. Can you give us any information as to the possibility of diverting the water from the Snowy River and the Eucumbene and throwing it over the range into the Murrumbidgee valley? I have no information upon that point. The lowest part of the range is between the two roads, and at the lowest point there would be a natural flow into Slack's Creek.
2620. That is one of the heads of the Murrumbidgee? Yes.

Mr. C. Haylock. 27 Nov., 1884.

Survey. 2621. What is the distance from the junction of Eucumbene and Snowy Rivers to Slack's Creek? Roughly speaking, about 20 miles.

Levels. 2622. Do you think it would be desirable to take levels and make a survey—do you think there is sufficient prospect of our being able to carry out the work? I do not think I should be right in hazarding an answer, because I do not know the levels. I have not worked out my own levels on to the Coolringdon Road. I can give you the difference of the levels by barometer from the gap near Coolringdon, at the head of Slack's Creek, and the levels of the river at Buckley's Crossing. Allowance must be made for the fall between the junction of the Eucumbene and Snowy Rivers and Buckley's Crossing. It would be impossible to say, without a knowledge of the levels, whether the work could or could not be carried out.

Discharge of Eucumbene River. 2623. Is there a great body of water coming down the Eucumbene? Not so much as on the Snowy River. The Eucumbene always runs; but the Snowy is the main river.

Snow water 2624. It is snow water? Yes—beautiful water.

Season of greatest discharge. 2625. At what time of the year has the Snowy River most water? It carries most when the summer is coming on.

2626. How long does it last? Until about January. It always flows, but the main body of water comes down when the snow commences to melt.

Diversion from Eucumbene and Snowy Rivers. 2627. *Mr. Donkin.*] You could not say from your own knowledge whether it would be possible to bring water from the junction of the Eucumbene and Snowy Rivers over the Dividing Range? I could not say from my own knowledge.

2628. *President.*] Have you any further general knowledge of the rivers which flow into the Snowy River? I have no further knowledge.

Width of gorge. 2629. *Mr. Donkin.*] Of what width is the gorge on the Murrumbidgee of which you speak? It is some years since I made the survey.

Depth. 2630. Is the river deep at that point? It was not running in any great body when I was there. It embraces a large watershed.

Fall of Murrumbidgee. 2631. *Mr. Gipps.*] What is the fall of the Murrumbidgee at the point you mention? I can hardly say.

2632. Can you give us no idea? It might be 5 or 6 feet in the mile.

2633. *President.*] Is it 5 chains across? Not the bed of the river.

Banks. 2634. Do the banks rise perpendicularly? The rocks come right into the alluvial banks of the river.

Rise of country. Area. 2635. *Mr. Donkin.*] But are you sure there would be 10 miles of water above this point? As you get to the range the country rises rapidly.

2636. That would be about 100 square miles? About that I think.

2637. You are returning to Cooma? Yes.

2638. Are you likely to be at the Eucumbene? I am not likely to be over there.

Reservoir in the Murrumbidgee. 2639. *President.*] You know of no other places similar to these? No, excepting on the Murrumbidgee—it is an unsurveyed portion of the river—there the river bed itself could be converted into a reservoir.

2640. Where is that? Just above Cooma. The country is very rough and precipitous, and it has never been surveyed. The reservoir could be made only by a masonry wall.

Masonry wall. Building material. 2641. That would be an expensive work? The material is to be found on both sides, and it is workable stone; lime is tolerably abundant.

Depth of rivers. 2642. What is the average depth in the case of the Eucumbene and Snowy Rivers? About 3 feet 6 inches—or say 3 feet taking the average.

Tantangara Creek. 2643. *Mr. Donkin.*] Is there any quantity of snow-water coming down the Tantangara Creek? There is not very much snow lying on Tantangara in the summer months.

2644. Is the river always running at this gorge? I believe it is.

THURSDAY, 4 DECEMBER, 1884.

Present:—

Mr BARTON, M.P.,	Mr. GIPPS, C.E.,
Mr. DONKIN, J.P.,	Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E.,	Mr. MURRAY, M.P.,

Mr. M'MORDIE, B.E., C.E.

W. J. LYNE, Esq., M.P., President, in the Chair.

Mr. Richard C. Webb called in and examined:—

Mr. R. C. Webb. 4 Dec., 1884.

2645. *President.*] Your residence is—? Kilfera, Darling district.

2646. How long have you resided there? A little over three years.

2647. Have you had experience of a variety of seasons? Yes, as I have been in the Riverina district about twenty years.

Kilfera Run. 2648. Have you effected any improvements on Kilfera Run? Yes, we have effected large water improvements in the shape of tanks and wells.

Wells. 2649. How many wells have you sunk? We generally sink trial shafts first. Within the last three years we have sunk from 150 to 200 trial shafts.

Trial shafts. 2650. Do you mean that you put down bores? No; the trial shafts are about 4 feet by 2 feet, and we run them down until we strike water.

Depth to water. 2651. At what depth do you strike water as a rule? From 40 to 190 feet. About 200 feet is the lowest depth which we have done without striking water. The water is always very salt at the shallow depths.

Depth to salt water. 2652. At what depth do you get salt water? The nearest the surface is 40 feet. I have had some of the water analysed, and it contained 2,200 grains of salt to the imperial gallon.

Strata. 2653. In what kind of strata do you find the salt water? In different kinds of strata; sometimes in clay and ironstone, and sometimes in drift.

2654. Have you ever had samples of the strata submitted for analysis? No. I have not heard of any one having had that done. The greater part of the strata through which we pass is clay and gypsum.

Rise of salt water. 2655. Does the salt water rise in the shafts? Yes, in some cases as we go down the water rises very high.

Mr. R. C. Webb. 4 Dec., 1884.

2656. How near to the surface? About 30 feet is the greatest rise we ever had.
2657. Do you put down bores? Yes, in nearly all the wells; we could not use the water unless we put down tubes a good distance below the salt water. We find that the deeper we go the better the water is.
2658. Does not the water rise to the surface when you tube the bores? No; we have not gone deep enough for that. We continue the bores until we get a sufficient supply of water for the stock. The further we bore the higher the water rises. We have not gone beyond 320 feet in any of the bores. — Depth to water. Rise of water.
2659. In how many of the 200 trial shafts did you succeed in getting good water? We have only two wells in which there is really good water, and that is water on which human beings could not live for any length of time. The water which we call very good contains about 500 grains of salt to the gallon, but we use some which contains as much as 900 grains to the gallon; but it is not a good thing to use such water in a dry season. — Good water.
2660. In how many of your wells is the water sufficiently pure for stock? Twelve. North of the Willandra we cannot get good water. — Water north of Willandra.
2661. Have you any wells north of the Willandra? We have one or two about 10 miles back, but after that there is not one good well.
2662. How do you account for the water being struck at different depths? If we sink a well in a hollow we strike water much sooner than in a well on an eminence. — Cause of varying depth to water.
2663. Then the water must come from the same strata in the different wells? That would appear to be so, judging by the depths in relation to the surface; but it is not so judging by the quality of the water, as in some of the wells it is very much salter than it is in others. — Source of water. Quality of water.
2664. What is about the average depth at which you strike water? About 100 feet; but we have to go down from 160 to 180 feet to get a good supply. — Average depth.
2665. Is the strata between the two points water-bearing? Nearly always; but sometimes there is a break of a few feet. — Water-bearing strata.
2666. Is the strata all the way down the description of clay which you have mentioned, or is there any sand drift? The strata is always changing; there is a change every 2 or 3 feet, except when we get a sandstone bar. — Nature of strata.
2667. And what is the thickness of the sandstone? The thickest bar we have had has been about 20 feet. — Sandstone bar.
2668. At what depth was that from the surface? From 90 to 100 feet. We had to sink 165 feet in that shaft before we got water. — Depth from surface.
2669. Do I understand you to say that the strata through which you pass from the time when you first strike water until you discontinue sinking is generally water-bearing? Yes, the quantity increases as we go down; we continue the shafts until the water gets too strong. I have seen the water rush up carrying 4 feet of earth with it. — Supply from water-bearing strata.
2670. To what height does the water usually rise in the wells? It varies; in some cases it rises 60 feet from the main spring, and in others only 16 feet. — Rise of water.
2671. Take the well in which you say that the water rises 60 feet, can you reduce the water materially by watering stock from it? We can lower it about 10 feet.
2672. How long does it take before the water regains its original level? I have not taken particular notice of that, but I should say about half an hour.
2673. What quantity of stock can you water at that well? Any number; there is an endless supply of water. — Supply.
2674. How do you raise the water? We have steam pumps in some of the wells; but we generally use whims with 60-gallon buckets, which will raise from 2,000 to 2,500 gallons per hour. — Raising of water.
2675. What is the nature of the surface of the Kilfera country? It is covered with salt and cotton bush and scrub, and is very flat, there not being a rise of more than 100 feet all through it. — Nature of surface.
2676. How far is your station from the Darling? The nearest point is about 60 miles. — Distance from the Darling.
2677. Have you observed that the water flows in any particular direction in the wells? No, the water seems to come in on all sides. I have heard it stated that there is a flow from the north-east to the south-west. — Direction of water-flow.
2678. Then the water comes from the mountains? Yes; the well-sinkers have told me that.
2679. Have you made any improvements for the storage of surface water? Yes; we have some very large tanks, and we have found them much more successful for stock than wells are. — Storage of surface water.
2680. Is the nature of the surface such as will hold water? Yes. — Nature of surface.
2681. What is the size of your tanks? From 10,000 to 17,000 yards. (*Appendix* Q 1.) — Size of tanks.
2682. What depth? From 15 to 20 feet.
2683. What do you consider the best depth for a tank? It depends on the size; a 10,000 yards tank ought not to be less than 15 feet in depth, and any size beyond that 20 feet; you cannot have a tank too deep. — Depth.
2684. Do you use ordinary scoops? No, the work is done with ploughs and horses and drays. The seasons have been too bad to permit of scoops being used. — Appliances to dig the tank.
2685. Why? Because it takes more horses to work them.
2686. What is about the cost per yard? We have let large contracts of 100,000 yards each, and in consequence have had the excavation done for 11½d. per yard. — Cost.
2687. But there are other expenses? Yes; the cost of boxes, shoots, drains, and fencing, brings up the total cost to about 14d. per yard.
2688. Have you made any dams in the watercourses? No; the country is too low for dams to be of any use. — Dams.
2689. Are there any inundations? There are small swamps where we make the tanks. If cane grass is growing in the swamp we make the tank on the edge, because these swamps are generally very dirty; we divert the water which would run into the swamp into the tank. If there is a box swamp, we make the tank in it, because in box swamps the water is clear. — Swamps.
2690. The tanks in the box swamps are of larger capacity than those which are made on the edges of the cane swamps? Yes, because they hold twice as much water above the surface as in the excavation. — Capacity of tanks.
2691. Have you any idea as to the extent of the evaporation? I have not made actual tests, but I do not think that the evaporation is as great as it is supposed to be. There is a good deal of soakage when the water is stored above the surface, but not much where the water is contained in the excavation. — Evaporation. Soakage.
2692. Have you seen any of the ana-branches of the Darling? Yes, I have crossed them. — Ana-branches of Darling.

Mr. R. C. Webb. 4 Dec., 1884.

Value of country. 2693. Do you think that any advantage would be gained by diverting water from the river into the ana branches? The advantage would be very great, and I believe that by putting weirs in the river the advantage could be gained without any injury whatever to the people lower down. By diverting water into the ana-branches the value of the country would be enhanced 400 or 500 per cent. The Lachlan and the Darling country carry a great deal more stock after the ana-branches have been flooded than at other times.

Nature of country. 2694. Is the country of such a level nature that water could be thrown back a considerable distance in time of flood? There is very little rise or fall in the Darling country—it is almost level. If a weir were put in the Lachlan so as to run water into the Willandra, that country would carry much more stock than it does at the present time.

Quality of land. 2695. It is all good country there? Yes, when there is water; but during the last three years the country has carried next to no stock, owing to the want of water.

Weir on the Darling. 2696. Do you think that an ordinary weir would stand on the Darling? If it were well constructed, I should think that it would; there would be nothing to prevent it standing, as there is no heavy rush of water in the river; it is a very sluggish stream. The Lachlan is dammed in many places now. These dams stand well enough, but they are generally cut away when water is wanted.

Dams on the Lachlan. 2697. They are large dams? Yes, they are above the level of the channel.

Overshot dams. 2698. Do not you think it would be better to have overshot dams? Yes, I think that they would be much the best.

Danger to banks. 2699. Do you think that with an overshot dam there would be any danger of the banks giving way? No, there would be no risk beyond that which usually exists in connection with dams. A large quantity of

Waste of water. water is run to waste owing to the want of a system of dams. The other day there was a rise of 8 feet in the Lachlan; the water ran for some time, and if there had been a weir across the stream a fair flood would have been sent down the Willandra.

2700. If you were supplied with a parish map could you mark the positions of your wells on it? Yes.

Depth of bores. 2701. *Mr. Franklin.*] Have any bores been put down in your part of the country to a greater depth than you have stated? There are no bores deeper than 300 feet. Boring is a difficult and an expensive undertaking.

Record of strata. 2702. Have you kept any record of the strata passed through in sinking the various wells on your run? No.

Formation. 2703. Is the country in which you find water in your district nearly the same formation as is seen in a section of the Murrumbidgee? I have not seen the strata of the Murrumbidgee wells, but I know that the water from those wells is much superior to that in ours.

Sample of strata. 2704. Can you supply us with a general sample of the strata passed through in your wells? Yes.

Situation for tanks. 2705. What, in your opinion, are the best situations for large tanks in that country? On the edges of the large swamps. I should never make a tank in a cane-grass swamp, because those swamps hold a tremendous lot of earth in suspense, and if a tank were made in one of them the water would soon become impregnated with clay. If you were to take a 10-inch bucketful of water from one of those swamps, and were to precipitate the mud with gypsum, you would find 2 inches of sediment settled on the bottom.

Drainage levels. 2706. In selecting a site for a tank how do you prove the drainage levels—by instruments? We do if we have any doubts, but as a rule this is not necessary, as there are sufficient indications to show which way the water runs. If we are making a tank on the edge of a swamp we select the lowest corner, and make drains all around the swamp.

Collecting the water by open drains. Silt-tanks. 2707. What means do you adopt for collecting the water from the drainage area beyond any given point above the tank? Open drains which lead into a silt-tank, from which a flume conveys the water into the large tank. The majority of people have not made silt-tanks, and the result is that the tanks are filled up with mud in the course of a year or two, and become large bogholes.

Disposal of spoil. 2708. How do you dispose of the earth taken out in excavating the tanks? It is formed into banks a chain and a half away from the tanks. These banks prevent the sand from blowing into the tanks, and they have this further advantage, that is, if there has been a good fall of rain we can pump a large quantity

Storage above level of ground. of water into the tanks from the swamps. This water is stored above the level of the ground.

Slope of batters. 2709. Do you make the tanks so that stock may go to them for water? Yes, in all cases. I notice that the Government make tanks with steep sides of 1 in 1, but this is a mistake, as the wash undermines the banks, carries dirt into the tanks, and ultimately reduces the slope to 3 to 1. The tanks might as well be made on this slope in the first instance.

2710. With a 3 to 1 slope is it necessary to have any protection in the shape of an apron? No; that slope is rather steep for stock, but they can get to the water from it. All our dams have slopes of 4 to 1 or 5 to 1.

Trees around tanks. 2711. Have you done anything in the way of planting trees around the banks of the tanks? No; the seasons have been too dry, but I think that it would be an advantage.

Cost of trial shafts. 2712. *Mr. Murray.*] What is the cost of sinking the trial shafts to which you have referred? From 2s. 6d. to 5s. a foot. The average depths of the shafts is about 100 feet, and we reckon that they cost £15 each.

Abandoning the shafts. 2713. When are the shafts abandoned? As soon as water is struck generally. Directly the men strike water they bring me a sample of it, and if I find that it is too salt for stock the shaft is abandoned, but otherwise the shaft is proceeded with. We do not proceed with the shafts now if we find that the water contains more than 800 grains of salt per gallon.

Particulars sent to Department of Mines. 2714. What are the depths of the wells in which you have struck what you call good water? I have sent full particulars respecting the wells to the Mines Department.

2715. *President.*] Would you have any objection to the document being added as an appendix to your evidence? Not the least. (*Appendix* Q 2.)

Proportion of salt. 2716. *Mr. Murray.*] What is the maximum proportion of salt in water which is fit for stock? It all depends on the feed which the sheep get. If they get good feed they may drink water containing 900 grains of salt to the gallon; but as a rule it is not safe for them to drink water containing more than from 600 to 650 grains per gallon.

2717. Is it upon the quality or quantity of feed that the use of the water depends? If there is abundance of feed the sheep can drink salter water than they can otherwise.

Nature of strata. 2718. What is the nature of the strata in the shafts when you get down from 130 to 160 feet? In some cases there is coarse drift, and in others a sort of white pipeclay.

2719.

Mr. R. C. Webb. 4 Dec., 1884.

2719. Do not you think it likely that if you were to go down deeper the water would improve in quality? I am convinced that we should get an artesian supply of fresh water if we were to go through the salt beds.

Depth to perfectly pure water.

2720. At what depth do you think that you would get perfectly pure water? Between 700 and 1,000 feet.

Test boring.

2721. *President.*] Do you think that the indications are sufficient to justify the Government in putting down a bore to test the water at lower depths? Yes. In putting down bores we found that in almost every 10 feet there was an improvement in the quality of the water; but we have not been able to bore any deeper, as the men do not understand the working of the apparatus.

Price of excavating.

2722. *Mr. M'Mordie.*] You said that you had tanks excavated at 11½d. per yard: did the contractors find horses, plant, and everything necessary for doing the work? Yes, but we allowed them grass for their horses. That price was paid for excavating only. The price was low because the job was a large one. We have paid as high as 1s. 6d. per yard for excavating.

Cost of well sinking.

2723. *Mr. Donkin.*] What is the cost of sinking wells? The mere sinking costs 30s. per foot; we find the casing, and the contractor puts it in.

Piping.

2724. What do you tube the bores with? 3-inch iron piping.

Boring rods.

2725. What boring machine do you use? Ordinary boring rods, worked by hand power.

Tiffin borer.

2726. Have you tried any of the American machines? No. I have seen the Tiffin borer at work, but it is only good to about 250 feet.

Cost of bore 700 feet long.

2727. What do you think it would cost the Government to put down a bore 700 feet and to case it? I cannot speak with any authority, but I should say about £3 per foot.

Test bores.

2728. Have the pastoral lessees in your district asked the Government to put down test bores? I do not think so.

Supply from wells.

2729. I suppose that in time of drought you look upon the wells as the only reliable source of supply of water? Certainly they are the most reliable, but I do not think that a well is as valuable as a good tank.

2730. Have you heard of any instances of the water flowing over the surface from wells sunk in your district? No.

Artesian supply.

2731. Do you think that if a bore were put down 1,000 or 2,000 feet, that an artesian supply would be found? I do.

Silt in Lachlan River.

2732. *Mr. Gipps.*] Does the Lachlan River bring down much silt? No.

Weir across the Lachlan.

2733. *President.*] Is there any more information which you can give us? I think that it is important that a weir should be put across the Lachlan; it would provide water for almost as much country as the Lachlan does in its course from where the Willandra outlets to its junction with the Murrumbidgee. That country is practically useless now in dry seasons.

Wells between Mossgiel and Wilcannia.

2734. *Mr. Franklin.*] Do you know whether the wells on the stock route between Mossgiel and Wilcannia contain a permanent supply of water? They do, but the water is very salt.

Well at Jumping Sand Hill.

2735. Do you know the well at Jumping Sand Hill? Yes; it is a good well as far as a supply of water is concerned. Sheep will drink the water, but horses and cattle do not care about it. A 20,000-yard tank would be much more useful there.

Lakes below Oxley.

2736. Do you know whether the lakes into which a diversion has been made from the Lachlan, below Oxley, contain permanent water? I think that they are dry at the present time.

Diversion into the Willandra.

2737. *President.*] Suppose a weir were to be thrown across the Lachlan to divert water down the Willandra, do you think that the work ought to be undertaken by the Government, or by the inhabitants—they borrowing the money from the Government and guaranteeing the payment of principal and interest? The country being Crown Land, which is open to selection, I think that the Government ought to do the work. They might demand a contribution from the men on the frontages.

Local Trust.

2738. Do you think that the work ought to be done under the direction of the Government or of a local body? I think that a local body would be the best.

Rate.

2739. *Mr. Murray.*] Do you think that the pastoral lessees or others who would be benefited by the work would submit to a tax which would cover the interest on the money expended? I think that they would be only too glad to do so. I think that the men on the Willandra proper would pay nearly the whole of the cost of a weir, if the Government would ensure them against the weir being damaged by other people.

Mr. Alexander M'Queen called in and examined:—

M. A. M'Queen. 4 Dec., 1884.

2740. *President.*] Where do you reside? At Nap Nap, on the Murrumbidgee, 45 miles below Hay.

2741. Have you been there for any length of time? Six years.

2742. Has Nap Nap a frontage to the Murrumbidgee? Yes.

Flow in Murrumbidgee River.

2743. Is there always a good stream of water running down the river? It has been very low this year; there are some places where a man might have stepped across the river this season.

Bed of the river.

2744. What is the nature of the bed of the river? Stiff marly clay.

2745. Is it not sandy? No, there is not much sand in our part of the river.

Depth of water.

2746. What depth of water has there been running down the river this year? I do not suppose that at any time there has been more than 7 or 8 feet.

Width.

2747. By what width? Perhaps 50 or 60 yards.

2748. But you said just now that a man might step across it? That is where there are logs. I do not think that the water would reach more than half-way to a man's knees in crossing at any of the fords.

Diversion into the Yanko.

2749. I suppose that you have heard that a proposal has been made to divert a portion of the water of the Murrumbidgee down the Yanko Creek? Yes. I think that if it were carried out, it would seriously affect the water below.

Injury to the country below.

2750. That is presuming that the water is taken when the river is low? The lower the water is taken from the river, the more will the country below be affected.

Widening of Yanko cutting.

2751 But do you think that any injury would be done to the country below if the water were taken when there was a good stream running down the river? The Yanko cutting might be widened, and by this means a large quantity of water might be stored at flood-time, but the cutting ought not to be lowered. You must bear in mind that the greater part of the Lower Murrumbidgee country depends upon being flooded.

Mr. A. M'Queen. 4 Dec., 1884.

2752. What effect has a flood on it? Very little grass grows until after the country has been flooded. I have about 80,000 acres of polygonum country there, and if a large quantity of water were diverted higher up, that country would be very much depreciated.

Diversion at flood-time.

2753. Suppose that water were diverted into the Yanko Creek at flood-time, do you think that a sufficient quantity would be taken away to materially affect the height of the flood in the river? It all depends upon the height at which the water is taken.

Protection by a sluice.

2754. Suppose a cutting were made into the Yanko, and were protected by a sluice, and only as much water taken off as was absolutely required, do you think that it would affect the flood-water below? I think that any cutting would be objectionable. From what I know of the people below, I do not think that they would object to the opening into the Yanko being widened at the present level, so that when there was an outflow in the river a larger quantity of water would go down, but the idea of making a cutting to let the water run into the Yanko would be very much objected to.

The present cutting.

2755. But there is a cutting there now? Yes, but that is very different from the one which it is proposed to make. We do not believe in the water being diverted at all. The country from Hay to the junction of the Murrumbidgee and the Murray is dependent on plenty of water going down the river.

Effect of a weir.

2756. Do you think that if a weir were put in the Murrumbidgee at Wagga or Narrandera, it would affect the water flowing below? I think so.

2757. Even supposing that the diversion of the water into the creek was regulated by a sluice, and was under the control of a responsible person? I think that any diversion of the water except at a certain height would be injurious to the lower part of the river.

Level of diversion.

2758. What height would you suggest? The river must be 20 feet above summer level at Wagga before it will flood our country and fill up the lakes and lagoons.

2759. You would not like the water to be run into the ana-branches at a lower height than 20 feet? I should not like the water to be taken at a lower level unless there happened to be two good floods in one season, when the people higher up could take as much as they pleased.

2760. You would object to the water being interfered with in the first flood? Very much so.

Wells.

2761. Have you any wells on your run? Yes.

Depth.

2762. What are the depths? From 100 to 150 feet.

Quality of water.

2763. Is the water good as a rule? It is fairly good water for stock, except in one well.

Rise in shafts.

2764. Does the water rise in the shafts? There is plenty of it.

Source.

2765. Have you any idea as to the source of the water? It is usually found in beds of lignum, and I think that the source of it is the Murrumbidgee higher up, and that the water runs down an old channel.

Tanks.

2766. Have you any tanks? A large number.

Position.

2767. Where do you usually construct them? On hard ground where there is a good catchment area. The country is very level, and we generally select the base of an eminence.

Depth.

2768. What depth do you usually make the tanks? Up to 12 feet.

Capacity.

2769. What capacity? Up to 10,000 or 12,000 yards.

Evaporation.

2770. Is there much evaporation? A great deal.

2771. Have you made any tests to ascertain the amount of evaporation? No, but I have noticed that the water disappears more quickly in dry hot windy weather than it does at other times.

Dams.

2772. Have you any dams in the ana-branches? I have some on creeks into which the water flows at flood-times.

Overshot dams.

2773. Are they overshot dams? They are overflow dams.

2774. When the water rises to a certain height it flows over and runs into the next dam? Yes. Some of the creeks are not dammed because the people lower down would object to dams being made in them.

Objections.

2775. Suppose that you constructed overshot dams in those creeks, do you think that any objection would be raised to them? I think so. Some of the creeks terminate in large water-holes, and the water spreads over the plain. We make the best use of these natural features for the storage of water. Where the creeks have a continuous course the people object to dams being made.

Height of creeks.

2776. What is the height of the creeks above the ordinary level of the Murrumbidgee? I think that a survey which has been made of the Murrumbidgee shows that the fall of the river from Hay downwards is about 8 inches to the mile.

Straightened length of the river.

2777. *Mr. Franklin.*] What would be the difference in the length supposing that the river were to run straight, and the length of the river with all its sinuosities? About three times.

2778. So that a straight cut would increase the fall three times? I suppose so.

2779. Does the country fall at right angles to the river? It rises slightly on both sides of the river.

2780. Have you made any comparison of the ordinary level of the river and the level of the most depressed portion of your run away from the river? No.

Banks.

2781. *President.*] What is the height of the ana-branches above the summer level? As you go towards Balranald the banks get lower and that country gets flooded first. The further up you go, the higher the flood outlets are.

Height of flood outlets.

2782. What is the approximate height? Quite 15 feet, if not more.

Weirs.

2783. Do you know of any place on the river where a 3 or 4 feet weir would divert the water over a large extent of country? Not on the upper part of the river; on the lower part such weirs might be of some use.

Utilization of the flood-water.

2784. Do not you think it advisable that some means should be adopted to utilize the large quantity of water which runs to waste? It all depends on how it is to be utilized. The country on the lower part of the river must be flooded, to be of any use.

Canals.

2785. I am referring to flood-waters? Canals to carry the flood-water further inland would be of great value.

Government and Local Trusts.

2786. Do you think that such works should be undertaken by the Government or by local Trusts? I think that the Government ought to initiate the works or provide the means, and then allow local bodies to decide in what directions the canals should be made.

Navigation.

2787. *Mr. Franklin.*] Do you think that the maintenance of the navigation of the river (say) to Hay, is of greater consequence to the holders of property than the regulation of the flood-waters? The navigation of the river is of great importance to all the station-holders below Hay. It would require a great deal of consideration to determine which of the two things is the most important. The distribution of the flood-water would be of immense advantage, and I think that it might be regulated without in any way interfering with the navigation. It would be a bad thing for the district if the navigation were interfered with.

Mr. A. M'Queen. 4 Dec., 1884.

2788. We find that there is an enormous volume of water carried away by the Murrumbidgee, which is simply wasted, in order to keep up a certain level for navigation only to a point as far as Hay: would it not be of greater benefit to the district to conserve that water than to provide for the navigation? That is a very difficult question to answer—I should not like to express an opinion.

Velocity.

2789. Could you supply us with a monthly statement showing the velocity of the river at your place? Yes; I shall be most happy to supply the Commission with any information which it is in my power to supply.

Depth.

2790. *Mr. Murray.*] What is the depth of the river at your place at the present time? Up to 4 feet.

Waste of water.

2791. Does not a large quantity of water go past your place to waste? Occasionally, but there has been no waste water during the last two or three years.

2792. I suppose that in flood-time only a small proportion of the water is required to fill the tanks which you speak of? Yes; a vast quantity of water goes to waste in flood-time. This is the water which ought to be stored.

Effect of weirs.

2793. Could not the water be raised by weirs to answer the same purpose as floods? Yes, on the lower part of the river, but it would be useless on the upper part, as the tanks are too high.

2794. *Mr. Gipps.*] What is the value of the river traffic at Hay? I have no idea.

Pumping water into canals.

2795. Suppose that the river were raised by a movable weir 10 feet, could not sufficient motive power be got out of it to pump up a large supply of water? I know that some years ago Mr. C. B. Fisher had an idea of that kind—he thought that he might be able to pump water into canals several miles back from the river. Such an undertaking is quite feasible, but I do not know whether it would be profitable. So long as the river flows we can run the stock 6 miles out, and the water would have to be conveyed beyond that to be of any use.

Low state of the river.

2796. *President.*] Have you ever known the Murrumbidgee to be so low that there was a danger of the supply of water for stock running short? I have not, but I have heard of it. There has always been a stream in the river since I have been in the district, and I believe that the river was lower last spring than it has been for twenty-five years.

Mr. James Tyson called in and examined:—

Mr. J. Tyson. 4 Dec., 1884.

2797. *President.*] You have a number of stations in Queensland and in New South Wales? Yes.

2798. Have you any stations on the banks of the Murrumbidgee? Yes.

2799. Is the Murrumbidgee as low this year as you have ever seen it? No, it is not low at all.

Low state of the Murrumbidgee.

2800. How many years is it since you knew the river to be lower than it is now? I remember three occasions when I have seen the river dry; in 1841 you could walk along the bed of it for 5 or 6 miles in places.

2801. How many years since? In 1841, and the last time in 1852; the other time was between those years.

2802. In what part of the river? At Groongal, near Hay.

River bed.

2803. Is the bed of the river sandy or hard? The bed is generally clay, with sand in the angles.

Dry river.

2804. And I suppose although the river was dry on these occasions, there was water in the bends? Yes.

2805. But there was no running stream? For miles there was no stream. In 1841 you could walk on the bed of the river for 5 or 6 miles.

Influence of stocking.

2806. Do you think that the stocking of the country since that period has caused a larger flow of water? Yes.

Filling up of the river.

2807. Then it is hardly likely that the state of things which you have described will exist again? The flow into the river is far greater than it used to be; but at the same time I notice that the river is filling up gradually. At one time there used to be large waterholes in the river, but these are all being filled up with silt now, and the river is a continuous stream. I think that this silt is washed in from the surface, which has been broken by stock grazing on it.

Mud

2808. Is that silt, sand, or mud? Mud generally; in some places it may be sand. Where the holes are filled with mud, they will not absorb water as they will where they are filled with sand.

Diversion into the Yanko.

2809. I suppose that you have heard of the proposal to divert a portion of the water in the river down the Yanko? I did not hear of it until just now.

Yanko cutting.

2810. Are you aware that some years ago a cutting was made into Yanko Creek for the purpose of diverting a portion of the flood-water in the river? I have seen the cutting.

Its effect further down.

2811. Do you think that it has in any way interfered with the flow of water further down? Not in flood-time. An overshot dam in the river at the entrance to the cutting would throw a great quantity of water into the cutting; and taking all the surroundings into consideration, I think that perhaps it would be wise in the interests of the country to put a shallow dam there, so that when there was a flood, a large quantity of water might be forced into the cutting.

Overshot dam.

2812. By doing that, you do not think that the people lower down would be injured? Not when there was a high flood.

Firm ground.

2813. Do you think that if such a channel were made, it would be wise to leave it unprotected? There is no fear of any wear or tear in a cutting there, because the ground is very firm. It is where the sides of a cutting get undermined by the water that the mischief is done.

2814. You do not think that there would be any danger of earth from the cutting being washed into the river? No

Danger to banks.

2815. Suppose that the inlet to the creek were inclined and the earth taken away, do you think there would be any danger of the banks being undermined? I do not think so, as the work would not dam a sufficient quantity of water to do any damage or to enlarge the creek all the way along—it might do so to a slight extent at the inlet. My idea is that where the channel is narrow it should be widened—all obstructions should be removed, so that when there was a flood in the river there would be a big gush of water down the channel. Let it be understood that I recommend that a dam should be made in the river only to force the water down the cutting while the flood lasted. It would have to be understood that the water should not be used for irrigation, but simply for the purpose of making provision for a supply for stock in dry seasons.

Widening of the channel.

Water supply for stock.

Sluice.

2816. Do not you think that, to prevent the people wasting the water, it would be a good thing to have a sluice under the control of a responsible person? That would be a judicious and useful plan, as the water could be shut off when a sufficient supply had been sent down.

Height of weir.

2817. You do not think that an overshot dam in the river would interfere materially with the flow of water down the river? That would depend on the height of the weir.

Mr. J. Tyson, 4 Dec., 1884.

2818. What do you say about a weir 3 feet high? It would not do any harm when the river was high.

2819. Do you consider that the navigation of the river from Hay upwards is of any material importance? Not at all, considering that there is a railway to Hay.

Navigation.

2820. Is it of such importance that it ought to be allowed to stand in the way of the construction of a weir such as we have been speaking of? I do not think that under any circumstances there would ever be a great deal of navigation between Hay and Wagga. The stream is full of snags and overhanging timber, and altogether it is uncertain.

2821. What is your opinion as to the navigation between Hay and Balranald? The river is shallow at Gelan, 30 miles below Hay.

Effect of weir on inundation.

2822. Do you think that the construction of a weir at the inlet to the Yanko cutting, to intercept a portion of the flood-water, would lessen the inundation of the country lower down? It would. I am dependent in a large measure on floods—I should be starved off the country if it were not for flood-water. I may explain that the supply to the Yanko from the Murrumbidgee is dependent solely on the duration of the floods; it takes days and weeks before the water will run through. As illustrating the extent of absorption in some places, I may state that at Juanbung, above the junction of the Lachlan and the Murrumbidgee, you will see the water running into a creek for three weeks at a time, and all of a sudden the water disappears in a large fissure on the surface. You can hear the water rushing into the fissure a quarter of a mile away. By-and-by you will find that the water comes out half a mile away. After the water has been running for some time, if you ride over the ground underneath which the water passes, your horse will sink into it.

Large fissure.

Local supply in Yanko country.

2823. Is there anything further that you would like to say respecting the Yanko cutting? They ought to get a large local supply in the Yanko country, because it is such good holding ground there. I know that, in consequence of the levelness of the country, the water which may be run into the cutting is likely to back into the river unless the rise is of long duration or you put a dam at the inlet.

2824. Suppose that the water were diverted at half flood or full flood, for the purpose of enabling the people in the Yanko country to fill their dams and tanks, do you think that it would be seriously objected to, or that it would seriously affect the flow of water further down? I can hardly answer that question. Any water-holes which the people might make would not materially affect the flow in the river, but if they were to make a cutting into the back country and let a large quantity of water run on to the low land, that would affect it.

2825. Your experience extends over the whole Colony? Yes.

Holding nature of ground

2826. What is your experience of the country in the north of New South Wales, that is with reference to the holding nature of the ground? In some places it is good, and in other places bad; you cannot lay down any rule which will apply alike to all parts of the Colony. Everything is governed by local circumstances, and in dealing with the important question which you have in hand you must give full consideration to those local circumstances.

The Darling.

2827. Do you know much about the tributaries at the head of the Darling? I am familiar with the Darling from its source to its outflow, and with all its tributaries.

Places for impounding water.

2828. Do you know of any places at the heads of the river where it would be possible to impound any large quantity of water which could be run off and utilized in dry seasons? On the tributaries of the Darling there is good holding ground—there being abundance of grass which binds the soil—and I think that it would be quite possible to construct dams which would not be detrimental to the interests of the lower country; but this doctrine will not hold good in the lower part of the country, because you must remember that the country west of the dividing range is an inclined plane, and that the fall is much greater at the commencement of the plane than it is further, and ultimately it becomes almost a dead level.

Natural gorges.

2829. Do you know of any natural gorges across which dams might be constructed which would impound any large quantity of water? I cannot think of any such places at present. If it can be done—and I think that it can—it will be a great advantage, because the water will be under control. If you wish to impound any large quantity of water you must do it before the river reaches the level country—you must do it on the high land separating the watersheds of the rivers.

Weirs across the Lower Darling.

2830. Do you think that any good would be done by putting weirs across the Lower Darling? No, because it is not high enough, and besides the ground is too absorbent to enable you to get the water away. The ground is like ashes, and if you make an ana-branch the chances are that it will become the main channel in the course of time. If you were to put in a weir it would cause the river to silt up. The country is entirely different from the Yanko country.

Sluices.

2831. Do not you think that the cuttings into the Darling might be protected by sluices? No, because the action of the water would enlarge the cutting outside of the sluices, and then channels would be formed around the sluices, which would become quite useless. There is no stone or suitable material of any kind to enable you to make a good job of any such work.

Absence of building material.

Movable sluice.

2832. *Mr. Gipps.*] But suppose that we had a movable sluice, which would be raised when the river was low? It is all right in the river, but the difficulty is when you let the water go abroad. I have tried it myself many times. I know of places on the river where, if you were to put a dam across, the river in those parts would become dry and a new channel be formed, perhaps flowing 100 miles away. The land is usually higher on the banks of the river than it is anywhere else.

Dry lakes.

Dam across the Lachlan.

2833. *President.*] I suppose that there are many places where by diverting the water the dry lakes could be filled up? Yes; if a dam were made across the Lachlan below the Willandra Billabong, and other dams below that, the water would be turned across into the Darling.

Wells.

Salt water.

2834. Have you sunk many wells on your station on the Lachlan? Yes, but I got salt water in all of them. None of the wells is more than 80 feet deep, and the water is as salt as the sea. I may tell you that I have made several cuttings from the back-waters which has filled up a number of lakes, in some of which I have a supply of water for years to come. In one of these lakes the water is 50 feet deep. This cutting is from 1 to 6 miles long. I am making another cutting from Waljeirs, which will be about 20 miles in length. I make use of the natural depressions so far as they follow the course which the cutting is to take, and I excavate a canal in the ground between the depressions. Where I am making the cutting it is 30 feet wide, and from 4 to 7 feet in depth. I made another cutting between Lake Bonarey and the Merowie Creek; the lake was filled, and the water lasted for seven years, but during the last three years there has been no water in the lake.

Supply in lakes.

Canal connecting natural depressions.

2835. I suppose that the 20-mile cutting which you are making will divert nothing but flood-water? I only wish to intercept the flood-water.

Mr. Evan Evans called in and examined :—

Mr. E. Evans. 4 Dec., 1884.

2836. *President.*] Your residence is —? Roto, Lachlan District, near Hillston.

2837. What is the nature of the country? It is level country principally.

Wells. 2838. Have you done much in the way of searching for water by sinking wells? We have sunk several wells.

Depth to water. 2839. To what depth do you generally sink before you strike water? Our best wells are from 120 to 170 feet deep. The wells at about 120 feet are the best.

2840. Do I understand you to say that the shallow wells are the best? Yes.

Good water. 2841. Is it good fresh water? Yes, we have very good water; that in the wells at 120 feet deep is perfectly fresh. We have a couple of wells at 165 feet deep, in which the water is slightly sweet.

2842. Can you use that water for stock? Yes, it is fit for any purpose.

Rise in shaft. 2843. To what height does the water rise in the shaft? Very little—only about 8 feet; but there seems to be a very strong supply.

Supply. 2844. What number of sheep can you water at a single well? We could water as many sheep as you could bring to any of our wells.

2845. Have you any difficulty in lowering the water? Sometimes we have to work the whims extra fast to reduce the water to make repairs, but we find that we cannot get it down very low. In hauling the water for stock we could not reduce it; you might water 20,000 sheep at one well and you could not reduce the water.

Quality of water. 2846. Have you any wells in which the water is so salt that you cannot use it? No; the water is generally good—when we get it. There are one or two wells in which the supply is not very great, and we have sunk shafts 300 feet without getting water.

2847. Did you pass through any rock? No.

Nature of strata. 2848. What is the nature of the strata? A white clay; when we get through that, we come into sand drift in which we find the water.

2849. Is there a division between the fresh water you get at a shallow depth and the salt water? There is no apparent connection between the two supplies.

Tanks. 2850. Have you any tanks? Yes.

Size. 2851. Of what size? 10,000 yards.

Depth. 2852. Of what depth? About 16 feet.

Permanency of supply. 2853. Do you consider a 16-feet tank a permanent one? That all depends upon the catchment area. If you have a good drainage area into a 10,000-yard tank you will never see the bottom of it.

Silt tanks. 2854. Do you construct silt tanks? Yes, we always make a small tank of 2,000 yards to catch the silt.

Banks. 2855. Have you any tanks with banks around them into which you pump water above the ordinary surface level when there has been a heavy rainfall? Yes; we usually make our tanks in depressions on the surface.

2856. Do you consider that tanks are better than wells for stock purposes? I think so—where you make the tanks in good sites.

Distance from the Lachlan. 2857. How far is Roto from the Lachlan? The nearest point is about 15 miles.

Source of well water. 2858. Have you any idea of the source of the water in your wells? Certainly it is not connected with the river, because the depth is too great for that.

2859. Do you think it is simply surface water which gets away in flood-time, or does it come from any distance? I think that it must come from a great distance.

2860. If it came from a great distance would it not be artesian? We have never put down the bores sufficiently deep to test that; we are satisfied if we get a good supply.

Willandra Creek. 2861. Are there any ana-branches or billabongs running out of the Lachlan? There is the Willandra Creek.

Diversion of Lachlan waters. 2862. Do you think it would be advisable, in the interests of the people there, to attempt to deepen the channel into the Wallandra Creek and throw a portion of the Lachlan water into it? That has been done already—there are two cuttings into the Wallandra.

Willandra cuttings. 2863. Are they sufficiently large to divert any considerable quantity of water? When the river is running nearly a banker the water runs through the cuttings in the Willandra. The country is very level, and it would require a very deep cutting indeed to cause the water to run down the Willandra from summer level.

Direction of fall of country. 2864. In which direction does the country fall when you go out some distance along the Willandra? West.

Discharge of Willandra into the Murray. 2865. If the stream on the Willandra continued to run, would it go towards the Darling or the Murrumbidgee? I think it has been discovered that it runs into the Lower Murray near Euston.

Merowie Creek. 2866. Do you know of any other dry creeks on the Lachlan into which water might be diverted? There is Merowie Creek, which has a long course, into which a cutting might be made from the Lachlan.

Diversion into all creeks. 2867. Do you think it would be practicable or desirable to divert the water in flood-time into all the dry creeks? Yes.

Enhanced value of land. 2868. Do you think it would materially increase the value of the land? Certainly, because it would give us a plentiful supply of water.

Government and local Trusts. 2869. Do you think that any work of the kind ought to be undertaken by the Government, or by local Trusts, who would borrow the money from the Government and repay the principal and interest in the course of a term of years? I have not studied that question sufficiently well to justify me in giving an answer. If the squatters only had a tenure when they had the country, they could have done the work themselves in the same way as they made cuttings into the Willandra.

Origin of salt-water. 2870. Have you any theory as to the cause of there being salt water in the interior? I think there is a deposit of salt in the ground, because I find that after the wells have been freely worked for some time they become very much fresher, thus showing that there must be an exhaustion of minerals.

2871. Have you any wells where the salt water is above the fresh water? No.

Willandra cutting. 2872. Has water run into the Willandra through the cuttings from the Lachlan? Owing to the drought, the Lachlan has not been a banker for five years in these parts.

2873. Do you think it would be a wise thing to deepen the cuttings? I do.

2874. Could it be done without interfering with the flow of water further down? If the cuttings were deepened so that the water would run when the river was half a banker, there would be any quantity of water

Mr. E. Evans. 4 Dec., 1884.

water for the people lower down. After the dams were filled the water would have a tendency to go back to the river—(this would occur only in very high floods such as that of 1870)—so that the people below would not be deprived of their supply.

Dams.

2875. Are there any dams on the Willandra Creek? Yes.

2876. Are they overshot dams? No, they are all dams with high embankments, but they are situated so that the surplus water finds its way through a natural by-wash into the creek. Where there are two channels, one lower than the other, we dam the lowest. As far as I am concerned, I know that there has been no diversion of water from the creek.

Permanent supply.

2877. To make the supply in the dams permanent I suppose you would require a supply down the creek each year? Yes, the dams will not retain the water more than a year; my dams have not received any water from the river for four years—it is only when there has been a local thunder-storm that any water has run into them.

FRIDAY, 12 *DECEMBER*, 1884.

Present:—

MR. BARTON, M.P., | MR. GIPPS, C.E.,
MR. DONKIN, J.P., | MR. LYNE, M.P.,
MR. M'MORDIE, B.E., C.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. James Tyson further examined:—

Mr. J. Tyson. 12 Dec., 1884.

2878. *President.*] You produce a map of your station at the junction of the Lachlan and the Murrumbidgee Rivers (*Appendix* R)? Yes.

Juanbung station.

2879. What is the name of the station? Juanbung.

2880. You stated in your evidence the other day that you had made extensive cuttings to take water into the back country? Yes.

Cuttings to Lake Kerrish.

2881. Would you point out the cuttings as shown on the map? Yes. The first cutting is ¾ of a mile long, from the Murrumbidgee flooded country into lake Kerrish. The flooded country is about 12 miles from the river. The cutting is from 18 inches to 4 feet deep; it is 15 feet wide, and has a batter of 18 inches to the foot.

Fall of country.

2882. What is the fall from the flooded country into the lake? The lake is surrounded by a sand-hill, and when that is cut through the fall is very great—about 2 feet to the chain.

Fall of cutting.

2883. What is the fall of the cutting all the way through? At some remote period water ran into the lake through creeks, and in forming the connecting channel I have made use of portions of the old creeks which have not been filled up. The fall from the flooded country into the bed of the lake would be about 30 feet. The next cutting is into Bunumbur Lake. It takes the flood-waters of the Lachlan and the Murrumbidgee into the lake. The cutting is about 5 miles long; it is 8 feet wide, from 2½ to 5 feet deep, and has a slope of 3 to 1. The lake is about 10 miles from the Murrumbidgee, and 5 from the Lachlan.

Cutting to Bunumbur Lake.

Box country.

2884. Is that lygnum country? No; it is flooded box country; there is lygnum in some places. The next cutting is into Boochatam Lake. The cutting is from the Lachlan flooded country. It is from 4½ to 5 miles long, from 2 to 5 feet deep, 12 feet wide at the bottom, and has a slope of 3 to 1. The next cutting is from the Lachlan River into Comayjong Lake, and from that Lake into Box or Merowie Creek. The cutting is about 7 miles in length from the Lachlan; it is from 4 to 16 feet deep, 10 feet wide at the bottom, and has a slope of 1½ to 1. The cost of the cutting was £14,000.

Boochatam Lake.

Comayjong Lake.

Cost of cutting.

2885. How far down the Merowie Creek is the water conveyed? 50 or 60 miles.

Outrun of the water.

2886. Where does it go to then? It runs into open swamps.

2887. Does it not run into the Murrumbidgee? If there is a general overflow of water it runs into Lake Waldare. At ordinary times it goes into quagmires for scores of miles. The next cutting is on the east side of the run, within 5 miles of the boundary between Juanbung and Walgiers runs. A portion of the cutting was made about thirteen years ago, and it filled Lake Bungarie. The water which ran into the lake at that time lasted for eight or ten years. The cutting was about 2¼ miles long. The area of the lake is about 1¼ mile by 1 mile, and about 20 feet deep. The size of the cutting is 20 feet wide at the bottom by 5½ feet in depth, the slope being 3 to 1. This 5½ miles must be added to the 2¼ first made, giving a total of 7¾, besides from 12 to 16 miles of cutting and damming through flooded country on the Walgar Run, leading the water in a continuous stream towards Lake Bungarie.

Lake Bungarie.

Area of lakes.

2888. What is the area of the other lakes? Comayjong is about 1½ mile by 1 mile. It is a shallow lake, only about 8 feet deep. The area of Boochatam Lake when full is 4 miles by from 1 mile to 1¼, and from 30 to 50 feet deep. Bunumbur Lake is about 1½ mile by 1 mile, and 18 feet deep. The area of Kerrish Lake is 1½ mile by 1 mile, and the depth about 20 feet.

Stock watering from Lake Bungarie.

2889. Did you water your stock at Lake Bungarie for eight or ten years? Yes—a large number of stock. The lake watered four paddocks without any assistant supply except such as was collected during thunder-storms. No water has run into the lake from the river except on the occasion to which I refer. Two of the paddocks are 8 miles by 5, and the others 10 miles by 5.

Carrying capacity of the run.

2890. What would be the difference in the carrying capacity of the run without these improvements, and with them? It would be vast, as the cutting is into the sole of the run, and there is water all around that—the river frontage is nothing compared with that. In an unimproved state the eastern part of my station in which this lake is situated would not carry more than 20,000 sheep; there are now on it 50,000 sheep; I have had more than that number of sheep on it. The other part of the run is uncertain, as it depends on flood-water. The Murrumbidgee throws water about 12 miles up the Lachlan channel and irrigates the intervening country. When the waters of the two rivers meet, there is a general overflow and the country is flooded for a considerable distance. When you get down the Lachlan you cannot find any regular channel into the Murrumbidgee—there is a series of small channels. There is not sufficient current for the waters to form a defined channel. The whole country becomes inundated, and in good seasons it is fine country, but without being irrigated by floods it will not keep many stock. The only lakes which have water in them at the present time are Bungarie and Bunumbur. Without the lakes the run would not carry more than 20,000 sheep, but at present it would keep between 40,000 and 50,000 sheep.

Mr. J. Tyson. 12 Dec., 1884.

2891. Is that in a bad season? In an ordinary season.
2892. What is the acreage of the first part of the run which you have described? Twenty miles by 20, or about 256,000 acres. Area.
2893. What is the area of the other part of the run which you have described—the part which you say is uncertain? About 400 square miles. I pay £500 a year rent on this run on which, without the improvements which I have made, there would not be a drop of water, and the only portion of it which would be available for stock would be that which is contiguous to the rivers.
2894. What is the total area of your run? Juanbung back run is 400 square miles; Sahara and Sahara North, 100 square miles each; Sahara No. 2, 60 square miles; Cooncombera, 70 square miles; Toorong, 50 square miles; Juanbung proper, 30; or about 810 square miles in all.
2895. And you say that country will carry only from 40,000 to 50,000 sheep? I do not know where you could pack them to make it carry more. It is waterless country. I have had tanks there without water in them for the last five years. Waterless country.
2896. How many wells have you on this run? Over ten have been dug, but there was salt water in them all. Wells.
2897. How many tanks are there? I could not give the exact number; I believe there are nearly thirty. Tanks.
2898. And there is not a drop of water in them? Not a drop.
2899. What area do they represent? It is marked on the map in each case.
2900. Have you any other runs mapped out and showing similar works conveying water from rivers? I have no other runs upon which so much work has been done. I have been in occupation of this run since July, 1846. Works on other runs.
2901. Have you carried out similar work on any other rivers? I have not.
2902. Do you think that weirs placed on the Darling at suitable places would stand? I do not think they would. Weirs on the Darling.
2903. Can you give us your reasons for thinking so? Readily. It appears to me that a large portion of the Riverina was at one time a lake; which evidently broke out at the Mallee Cliffs on the Lower Murray, between Euston and Wentworth. I speak generally of the water systems of the Murray, the Murrumbidgee, the Lachlan, the Darling, and the Warrego. These rivers run down an inclined plane westerly; but the fall is gradually lost and a dead level is almost eventually reached. This appears to me to have been the bed of the lake. The earth in the neighbourhood of the rivers is a sort of silt; there is no clay—it is a deposit; you could not make bricks out of it; it is vegetable matter that has been in solution. When the rivers run down into the neighbourhood of the low country there is an overflow, and as they get down lower a general inundation. The rivers mingle with one another. If there is a heavy flood, and the Murray comes down first she discharges her water into the Murrumbidgee, and if the Murrumbidgee comes down first she will discharge her water into the Murray near their junctions. Riverina a former lake. Nature of deposit. Floods. The rivers discharging mutually one into the other.
2904. And the same with the Lachlan and Darling? Precisely the same. The water will flow from the river which is highest into the river which is lowest or its next neighbour. This country being composed of silt, I think you could not make a dam which would stand. The country is a perfect quagmire in flood-time. If you were to make a dam, the water would run out and make a course in another direction. Country composed of silt. Dams.
2905. You think it would wash out? Yes; you have nothing to hold it. From the nature of the country, it becomes generally inundated; it is inundated at times 20 miles wide.
2906. Do you think it would be possible to keep the channel clear by removing the silt, and to prevent the bywash by giving the protection of a sluice? The sluice and all would go. Anything you did would be affected by the flood. I have been living in the neighbourhood of the Murray and its waters ever since I was nineteen, and I know of nothing which you could do. When you find the river bank high at any one place, such as Wilcannia, it is low on the other side. I should regard the construction of weirs in this part of the country as a perfect waste of money. If you turn the river out of its natural channel you have a difficulty before you; you can fill up the channel, but then you must make provision for the outflow, and how are you to do that? Removal of silt. Effect of floods.
2907. *Mr. Donkin.*] Then you think it impossible to weir the Darling or the Lower River Murrumbidgee? I do. These rivers, however, run out of country which is fit for cultivation—country in which clay is to be found, and in which weirs or cuttings could be made. Weirs on the Darling and Lower Murrumbidgee.
2908. Could you say approximately what is the northern boundary of the lake to which you refer? It ran through all the Colonies—at least that is my impression. The Barrier Range, I think, divides the waters of the Darling from those of Cooper's Creek. Northern boundary of the Riverina lake.
2909. *President.*] And the dip would come in from South Australia at the Bight? There is a dip on South Australia at Lake Eyre. The low country extends southerly and westerly into Victoria. There is more or less a border of mallee on the right, and on the left you have the western slopes of the main range as you look south. Dip.
2910. *Mr. Donkin.*] Have you been at Brewarrina—you know there is a natural weir there? Yes. Weir at Brewarrina.
2911. There is a fall of 4 feet—how does that weir stand? That is in accordance with what I have endeavoured to describe—it is a stone reef across the river. Here is a great elevation between the eastern and western waters. Going westerly the greater part of the elevation is lost in the first 100 or 200 miles; within that distance the country is firm, and is more or less fit for cultivation.
2912. Why does it not silt up at Brewarrina? Because it is high, and the water is swift.
2913. There is only a fall of about 8 inches to the mile? But it is solid ground. It seems to me that the water has been drawn out of an inland lake between the Gulf of Carpentaria and Spencer's Gulf. I believe that not so very long ago there was no Lower Murrumbidgee. If you examine the lower river closely you will see that there are evidences of newness as compared with the upper river. On the upper river there are trees 10 or 12 feet through; as you go down the river the trees grow smaller. The bed of the river is newer. There are roots in it, and I know of a place above Balranald where there is a tree standing in the middle of the river. Solid ground. Inland lake. Lower Murrumbidgee.
2914. Might not that have been caused by the silting up of the river—a tree growing there? It might. I admit that the river might change its course and leave a tree standing on an island, as it were; but there are other evidences of the newness of the river. Newness of river.
2915. Do you not think that the scanty timber might be attributed to the want of natural facilities for its growth in this plain country? It would be an indication of the poverty of the soil. Higher up, however, the river is well formed; it is deep, and has every appearance of an aged river. Cause of scanty timber.

Mr. J. Tyson. 12 Dec., 1884.

2916. *Mr. Gipps.*] Is the flood-water thrown back on each side of the Murrumbidgee—north and south? Yes, on both sides. If you find high land on one side it is generally low on the other, especially on the lower part.

Flood deposits.

2917. Does every flood deposit silt? Yes, every flood carries with it a sluicing of earthy matter. This cream is as it were left on the first flooded country—it enriches it; as the water gets down towards Hay or thereabouts it is comparatively clear.

2918. *President.*] The solution which is deposited is as good as a coating of manure? Yes; it renders the country more or less fertile.

Mallee country.

2919. *Mr. Donkin.*] The rich country then would be the mallee country? No; you find it long before you get to the mallee country. The flats in the neighbourhood of Wagga are formed by these silt deposits. The eye has a great deal to do with education in these matters, and I think that a school should be established in the country by the State. Young men might be taught engineering there; they would obtain a practical acquaintance with the country; and what they saw near them would be of great assistance to them.

Establishment of a school.

Inclination of the country.

2920. *Mr. Gipps.*] As regards the deposition of this silt, does it seem to preserve the level character of the country, or does it seem to give the plain gradually an inclination from north to south, bringing the rivers down to a focus? The general tendency is from east to west. It varies at certain points.

Stability of weirs.

2921. As regards the weirs, you think that no stability could be obtained? The whole country is a quagmire in times of rain.

Depth of deposit.

2922. *Mr. M'Mordie.*] What is the depth of the deposit? Several feet.

2923. Is there firm ground underneath that? As far as I am aware there is no firm ground. I do not know how it would be possible for you to carry out any works there.

Movable weirs.

2924. *Mr. Gipps.*] Suppose you constructed a movable weir, which in flood-time would offer no obstruction? I do not believe in movable weirs.

Worst part of country.

2925. *Mr. Donkin.*] Where is the worst part of this flooded country on the Darling? From the junction of the Warrego downwards—especially when you get down below Wilcannia.

Mr. John Clark Bowden called in and examined:—

Mr. J. C. Bowden. 12 Dec., 1884.

2926. *President.*] Your residence is at—? Balranald.

2927. Have you lived there for any length of time? Eleven years.

2928. Have you had any general experience of that part of the country; Yes; of the Murrumbidgee, the Lachlan country, and the Darling country, as far as Wilcannia.

Diversion into dry creeks, &c., of the Darling.

2929. Are you of opinion that any large quantity of flood-water could be utilized by being diverted into dry creeks and ana-branches of the Darling, without interfering with the general flow of the river? The Darling is the most difficult of the rivers to treat, because the floods are irregular. When there has been no "fresh" for a considerable time, the river becomes a chain of waterholes.

Weirs.

2930. Suppose weirs were placed across the river at various points, to impound water and in flood-time to divert it into dry creeks, do you think that that could be done to any great extent without interfering with the flow of water below? I do not think that it could be done to any great extent.

Volume of water.

2931. Do not you think that there would be sufficient volume of water in flood-time? In flood-time there would be; but the river does not rise regularly, like the Murray and the Murrumbidgee. If the river rose annually what you suggest might be done.

2932. Of course it could be done when the river did rise? Yes, when the river rose above a certain point.

Darling country.

2933. The Darling country is very level? Yes.

2934. Suppose a weir were put across the river, to what distance back do you think it would throw water—say a weir 10 feet high? I could not give any reliable idea.

Scour.

2935. Suppose weirs are constructed, do you think that there would be much scour at the outlets? Yes, unless great precautions were taken.

Sluices.

2936. Unless they were protected by sluices? Yes, any ordinary cutting made on the rivers would widen very rapidly.

Stability of weirs.

2937. Do you think that it is possible to erect weirs in the river which would stand? That will be for a professional man to say.

Talyawalka Creek.

2938. Do the flood-waters of the Darling run down Talyawalka Creek? Yes, very rapidly—the banks of the creeks are very steep.

2939. Do you know at what height the water must be in the river before it will run into that creek? No.

2940. You have had experience of the Lower Murrumbidgee? Yes.

2941. As far as Narrandera? No.

Lygnum swamp country.

2942. Is it absolutely necessary that the lygnum swamp country on the Lower Murrumbidgee should be flooded to make it productive? Yes.

Weir on the Murrumbidgee.

2943. Do you think that a weir 4 feet above the summer level of the Murrumbidgee, at (say) Narrandera would interfere with the flood-waters? I think that a weir would be very objectionable at that level. If the water is to be diverted a much higher level ought to be named. Any diversion of water at the level you state would interfere with navigation in bad seasons—such seasons as we have had during the last three years.

Navigation.

2944. Has there been any navigation this season? It has been spasmodic as far as Hay.

2945. Can you explain in what way a weir 4 feet above summer level would interfere with navigation? Because it would prevent the water coming through unless it rose above that height.

Diversion into the Yanko.

2946. Suppose a weir were put on the river where the Yanko cutting is, and this were protected by a sluice so that the water would be diverted only when there was a surplus, do you think that it would seriously affect the flow of water further down? That would all depend upon the height at which you took the water from the river.

2947. What height would you suggest? We judge the state of the river from the heights of it at certain points—say at Wagga and Gundagai. When it reaches a certain point at these two places, we can judge with tolerable accuracy what extent of country will be flooded lower down. My opinion is that

Diversion level.

no water should be diverted from the river until it has reached a height of 15 or 20 feet at Wagga or Gundagai. If the water were diverted at a lower level it would seriously affect navigation and also the

runs

runs and the lower part of the river, which rely solely on flood-water to make a large portion of them available for stock. Mr. J. C. Bowden.

2948. Suppose a stream of water 4 feet deep by 10 feet wide were let into the Yanko cutting when the river was 4 or 5 feet above summer level, would that seriously affect the flow below? It would certainly make a great difference in the river. I judge that from experience which I had at Balranald through the breaking of a dam on a creek running into the Murrumbidgee. When the water ran into the lake a dam was made to keep it back. This dam broke and raised the water in the river to such an extent that it was quite noticeable. 12 Dec., 1884. Effect of diversion on the Murrumbidgee.

2949. Did the water run out of the lake into the river? Yes.

2950. How did the water get into the lake? It ran down the creek from the river in flood-time.

2951. *Mr. M'Mordie.*] What is the fall of the channel from the lake to the river? I do not know; but the river is very level there. The rise in the river between high-flood and summer level would be about 12 feet. High floods and summer levels.

2952. What is the length of the channel from the river to the lake? Between 2 and 3 miles.

2953. What is the size of the lake? It is about 8 miles in circumference.

2954. *Mr. Barton.*] Have you any runs in the district? No; I am in business at Balranald, Hay, and Echuca.

2955. You lay particular stress on the necessity for a large flow of water in the river for navigation? Yes; and also because of the effect which the flood-waters have on the low-lying lands between Hay and Balranald. Wants of navigation.

2956. You cannot offer a professional opinion as to the effect of taking a certain quantity of water from the river? No.

2957. You simply imagine that if a certain quantity of water is taken from above a certain level it will have a certain effect—you have no knowledge to guide you? Except the knowledge which I have formed by watching the rivers most carefully. The rivers are watched daily. Balranald depends on navigation because it is the port of a large area of country.

2958. What is the draught of vessels trading on the river? The loaded draught of some is from 6 feet to 6 feet 6 inches, but there are smaller vessels. Draught of vessels.

2959. What depth of water would there be in the river in the shallowest places at ordinary summer level? From 1 foot to 1 foot 6 inches. I have seen it year after year as low as that in numerous places. Shallowest depth of water.

2960. Does the river remain long at that level without any rise in dry seasons? From January until the end of May at Balranald, and much longer—probably two months—at Hay.

2961. Then in bad seasons the river is navigable for six months in the year? To Balranald for five or six months, and to Hay for a period of one or two months shorter. Season of navigation.

2962. Every year? Yes.

2963. Have you any idea as to what height the river has to rise before the low-lying lands would be benefited to any considerable extent? At Balranald, 13 feet, and at Hay about 16 feet. These rises would flood from the Lachlan Junction downwards. I have figures showing the effect of the rises in the rivers in various places. Effect of rise of the river.

2964. Can you supply us with a copy of these figures? Yes.

2965. Have you any idea as to the mileage of the flood at various heights? Yes; I can supply that with the other information.* Mileage of the floods.

2966. *Mr. M'Mordie.*] How often does the river rise to 15 or 20 feet above summer-level during an ordinary year? It rose regularly from 1873 till 1877. We have not had a beneficial flood for five years. Frequence of rise above 15 feet.

2967. So that according to your idea, no water ought to have been diverted during that time? Yes.

2968. Have you any idea of the quantity of water which would run to waste to the sea? No, but it must be very large.

THURSDAY, 8 JANUARY, 1885.

Present:—

MR. DONKIN, J.P., | MR. GIPPS, C.E.,
MR. FRANKLIN, C.E., | MR. LYNE, M.P.,

MR. McMORDIE, B.E., C.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Charles Fartiere examined:—

2969. *President.*] Where do you live? I live at Marfield, near the 70-mile track, about 10 miles from "Hardy's Hotel," on Kilferra. Mr. C. Fartiere. 8 Jan., 1885.

2970. Is it near the road to Wilcannia? Yes, it is 10 miles north of the road.

2971. What is the area of the station? We are interested in two places; that one is between seven and eight hundred square miles.

2972. What kind of country is it? Scrub country. Nature of country.

2973. I mean the soil? It is sandy soil.

2974. Are there any claypans about it? There are cane-grass flats—not numerous, only scattered at long distances, quite sufficient for pastoral purposes, but not for cutting up into small areas.

2975. Have you improved the country much by making permanent water? Yes, we have made extensive improvements. Those improvements were commenced between three and four years ago, and they have been going on up to the present time. I can show large tanks of twelve and fifteen thousand yards that had never had a foot of water in them. To these tanks we have always put large drains—sometimes from 3 to 5 miles of drains. We have done all that we could to preserve water, and what I have stated has been the result. Improvements on the run. Tanks.

2976. Have you any tanks filled? At the present time I have only one tank on the run filled.

2977. What size is that? It is a 12,000 yards tank. Size.

2978. What is the general size of the tanks that you have made? From ten to twelve and fifteen thousand yards—generally from 10,000 to 12,000 yards. I find that tanks of a small capacity generally fail when they are most wanted.

2979.

* NOTE (*on revision*):—I regret I cannot furnish this information, as I have been unable to visit Balranald to obtain it.—J.C.B.

Mr. C. Fartiere. 8 Jan., 1885.

2979. How long do you consider that a 12,000 yards tank will last if there is a moderate quantity of stock on the run? I may mention that we make embankments round them. If we succeed in getting the tanks filled and embankments pumped up, we consider that they are good for a two years' supply for the number of stock that you can put on the country.

Capacity. 2980. How much water would a 12,000 yards tank hold? Approximately about 2,025,000 gallons, that is the contents of the excavation, when filled, irrespective of what can be retained in the embankments round the tank.

2981. How much difference will the embankment make? The embankment would increase the capacity of the tank by about one-third.

Evaporation. 2982. That would make it 16,000 yards? Yes; you cannot fill it to the top of the embankment—only half way. The increase is from one-third to one-half. Taking the evaporation into consideration, I should say one-third. There is a much larger evaporation when the water is above the surface, because it catches every breeze, and it goes much more quickly.

2983. You consider that it protects the lower water? It does decidedly.

Position of tanks. 2984. In what spots do you generally make your tank—in what kind of country? Always in the clay—in the hardest soil, in the cane-grass flats. If we are not able to get this country we go in for a larger amount of drainage, and we try and get into some natural depression in the soil.

Dry country. 2985. Have you any creeks running through Marfield? No, it is an entirely dry country; there is not a creek on it.

2986. You are entirely dependent on tanks and wells? Entirely.

2987. The country is not subject to floods at all? No, there is not a watercourse in it.

Nearest river. 2988. What distance off is the nearest river? About 90 miles.

2989. *Mr. Franklin.*] The nearest ana-branches? The nearest ana-branches will be about 70 miles distant.

Ana-branches. 2990. *President.*] Are there any dry ana-branches from the Darling coming near Marfield? No, they branch off lower down.

Central canal. 2991. Do you consider that it would be of great advantage if a central canal were brought down midway between the Lachlan and the Darling to convey water for filling those tanks at certain periods? I do not think that that would be practicable—we could never hope to get water by that means.

Objections. 2992. Why? I believe decidedly in a scheme of that kind being carried out, because according to my experience the larger amount of water that is conserved the greater is the rainfall. I do not think, however, that we could get a supply of water for our tanks by that means unless it was returned in the form of rain—the expense involved in bringing the water in small channels from the canal to the tanks would be too great. I think that the natural absorption of the soil would consume all the water that you could bring. I am a thorough believer in the idea of getting communication to the back country; it would be of great service as a means of transit for wool and supplies—it would materially lower the expense of working the stations.

Railways. 2993. That can be done by railways? Decidedly, if we get them.

2994. Of course you have been to the Darling? Yes, I have resided there. I am speaking now from twenty years' experience of the back country and fifteen years on the Darling.

The Darling. 2995. You know the stream of water running down the Darling? Yes; I travelled the Darling in 1868 and 1869, when it was looking as bad as it possibly could, and in 1870, when it was just at the other extreme.

Central canal. 2996. Do you not think it is practicable to bring down some of the waters of the Darling by a central canal? I do. I can show you the road that I travelled in 1870, and I know that then the waters of the Lachlan and the Darling were only a few miles apart.

Weirs and locks. 2997. But that was at a time when you did not want it? Yes, but if the water is conserved by means of weirs and locks we might have sufficient to bring it up to the requisite level.

Supply of tanks. 2998. I understood you to say that it was not possible to bring the water by a canal? I think you can bring the water down, but I doubt whether you can bring a sufficient supply for the tanks.

2999. Suppose it is practicable to bring the water down in the way I suggest, I suppose you will acknowledge that it is only a question of supply and demand as regards utilizing it in the tanks? Yes.

3000. If we can get a sufficient supply to fill the tanks, there is nothing to prevent it from being done? No; if you can get a sufficient supply of water it is practical enough, but that is what I doubt.

Flood waters. 3001. I should like you to point out on the map the route you took and the extent of the flood-waters in 1870? [*Witness indicated the route on the map.*] In 1870 I made a trip from Balranald to Pooncairie, and from Pooncairie to Wilcannia, taking a circuitous route through the whole country lying between Reed's Lake. those points. I was then acting as an appraiser. There is a lake in Monaro country called Reed's Lake that is not shown on the map. The lake was flooded in 1870 by the Darling River.

3002. How many miles is it from the bed of the Darling River? About 70 miles. Going from Balranald Lachlan water. near to Pooncairie I had to swim a strong running stream which came from the Lachlan. It must be between 40 and 50 miles from the river. I have gone over the country several times since then. I am Flow to the Murray. sure that there has been in past times a flow of water from the Lachlan to the Murray. At the time of which I speak the water would have found its way into the Murray if it had not been blocked by sand-hills a little higher up.

3003. Do you consider that the stream which you crossed was water which had flowed out of the Lachlan Willandra River. through the Willandra River and found its way down towards the Murray? Yes. If it had been Lake Golgol. assisted a little it would have found its way into the Murray at Lake Golgol, about 20 miles higher up the Murray River than the junction of the Darling and Murray Rivers, but being interfered with by the sand-hills it was turned and found its way into Lake Benenee, and some into the Warialda Lake. Warialda and Benenee Lakes.

3004. How far do you think the detour of that water went towards the Darling? The Lachlan water must have gone considerably over 100 miles.

Distance from the Darling. 3005. Towards the Darling? Yes.

3006. And how far would that be from the Darling water which you say flowed into Reed's Lake? A distance of from 30 to 40 miles.

3007. You have another station? Yes.

3008. Where is it situated? It is in the extreme north-west portion of the Colony, near the Queensland border.

3009.

Mr. C. Fartiere.

8 Jan., 1885.

3009. Is it near Mount Brown? Yes, the Connopie Downs is the name of the station. It is about 700 square miles.

3010. Is that a dry country? It is.

3011. Are there no creeks there? There are water-courses, but not regular running creeks.

Clay-pans.

3012. *Mr. Donkin.*] Are there no clay-pans there? Yes, there are, but there is a difference between creeks which are running regularly and water-courses which only run occasionally.

3013. *President.*] Where does the water come from? From the rains.

Local rainfall.

3014. Is there no connection with a river? No; we are simply dependent upon the local rainfall.

Bulla River. Salt water.

3015. Does not the Bulla water come down? That is in the clay-pans—not in creeks. The Bulla River ends on one of our blocks in an enormous swamp—one of the largest in the Colony. In connection with that I may mention a thing which much surprised me. I expected from the fact of so much water passing down the Bulla River and disappearing in the swamp that we should have very little difficulty in obtaining plenty of good water by sinking. Within 10 feet of the surface we have struck water, but it is as salt as the sea. It is perfectly useless, and the supply is so great that it seems almost impossible to get through it.

3016. Did you ever try to get through it by putting a pipe down? Not at Connopie, but I have been boring on the Marfield station.

Dry seasons.

3017. I am speaking of this particular swamp? No; I have had dry seasons to contend with the whole time. I have had the station three years, and there has been a drought from the commencement. It has been a struggle to get rations on to the station: I have had to pay as much as £4 a bag for flour as black as this cloth. I have had every disposition to get boring plant on to the ground, but I have been unable to do it.

Mineral salt.

3018. From your knowledge of the quantity of water that comes down the river, there must be a great deal that soaks into the ground? That is what I thought. My impression was that we should have no difficulty in getting a good supply for the stock. The water appears, however, to be so impregnated with some mineral salt that it is useless.

Soakage.

3019. Do you think that that water has soaked into the ground from the swamp? I believe it is the soakage water, and that the water is impregnated with minerals which exist in the ground.

Diversion.

3020. Is there any natural means by which the water that runs down there could be diverted to other parts and conserved? Yes, that could be done.

Cost.

3021. Without any very great cost? Yes, without any very large cost. It would require a few cuttings.

3022. Where could you send it to? The difficulty is that you would have to deal with a neighbouring Colony—we are close to Queensland.

Inlet of canal in Queensland.

3023. Would the water have to be diverted into Queensland? No, but some of the work in making the first cuttings in opening up the canal would require to be made on the Queensland side, to prevent the spread of the Bulla waters over the large flats and swamps before reaching the New South Wales boundary. The operations would have to be commenced further north than the boundary of New South Wales.

Swamp on the Queensland border. Lake Yantaira. Canal to the Bunker and Turkey.

3024. Suppose arrangements were made to divert the water, what part of the country of New South Wales would you bring it through—would you divert it from its present channel? There is a swamp on the Queensland border about 12 miles broad and between 40 and 50 miles long, which fills to a depth of from 12 to 15 feet when the Bulla River is in flood. The waters of the river could be diverted round one edge of the lake by a canal, and brought all through the dry country down to Lake Yantaira, a distance of about 30 miles. It is a mistake to allow the water to spread over a wide area. If a canal is made, the water is kept in a more confined space and there is less evaporation and soakage. The water could be prevented from entering any of those shallow dry lakes, and conveyed through the country by means of a canal into the Bunker and Turkey, which are fine natural water-courses. There are several other creeks, and a surveyor going out might discover a better route for the water. Taking the general lay of the country, I think it would be possible to do what I have suggested.

Flood of Bulla River. Soakage.

3025. You say that when the Bulla River is in flood large quantities of water overflow into the large clay-pans or lakes, from which the water soaks away or evaporates? Yes, it becomes useless, because when it goes into the ground it becomes salty.

Diversion to Bunker Creek.

3026. You suggest that that water could be diverted and taken round the edge of the lake, and conveyed through the dry country to the Bunker Creek? Yes.

3027. And by that conveyed towards the Darling near Wilcannia? Yes.

Filling tanks. Sandy nature of soil and heat.

3028. If that were done, do you not think it would be practicable, by making off-shoots all along that water-course, to fill any tanks that may be made? That is the same question that you asked before. I think that would mean such a consumption of water that you would not be able to obtain an adequate supply. You must take into consideration the sandy nature of the soil and the great heat there in the summer. An enormous quantity of water disappears even in a hard clay soil, by absorption and natural soakage, during the heat of the summer months.

Conservation in narrow channel. Water led by piping. Natural basins.

3029. But does not the water go into the swamps now and escape in that way, and could it not be conserved by being kept in a narrow channel: once the water was stored in that way, do you think the absorption would be so great that there would not be a supply for the tanks? I do not think that there would be no water left, but I do not think you could get a sufficient quantity to supply the tanks. You must consider the position of the tanks, and their distance apart. You would require many miles of communication to reach them. If it could be done by piping or something of that kind such an undertaking might be successful, but if you were to use open channels subject to evaporation and absorption I do not think that the supply of water would be sufficient. The quantity required would be something enormous. The tanks are from 7 to 12 miles apart, and in many cases they are much longer distances apart. I admit that there are plenty of natural basins which might be filled in the way you suggest, and no doubt if they were filled it would tend to increase the rainfall. That is where I think the beneficial part of the scheme would come in.

Tanks near canal —evaporation.

3030. But suppose that tanks from 15 to 25 feet in depth were made near the canal, the evaporation being small, do you not think that when they were once filled they would be almost permanent? Yes; where the tanks were within a short distance of the canal that would be quite practicable. My remarks apply only to the tanks as they are now dispersed over a large area of country, and situated in a very sandy soil; and to reach those tanks it would require cuttings which would chiefly have to be made through light sandy country.

Flow in the well.

Supply.

Artesian water.

3031. Suppose that the tanks were filled with the water which now goes into the swamps, do you not think that the loss by evaporation and soakage would be very much diminished? I am sure of it.

3032. You have sunk wells, have you not? Yes; but before leaving this question I wish to mention that from travelling over the country for a long time I know that there are many natural reservoirs which merely want a little assistance in the way of dams to make them very useful.

3033. It is necessary to raise the water to a sufficient height to fill these natural reservoirs at ordinary times? Yes, at ordinary times. A number of these have been great lakes; they are in good hard soil, and when once you have filled them and are able to keep them at anything like half their level it would add very materially to the rainfall of the district, because the amount of evaporation which takes place must tend to bring about a better rainfall than we have at present. In connection with this matter, I may say that I am quite sure that Mr. Russell's estimate of rainfall is far above what we have been getting—it is far above the average.

3034. But he makes his statements from ascertained facts? But he gets his records from stations which are on creeks or lakes, or something of that kind—places where there always is water, and where consequently the rainfall is much heavier than in other districts not far distant. Water on the surface always seems to have the effect of drawing the clouds, and there is always a bigger rainfall at those particular places where the records are kept than elsewhere, even greater than in localities not far from them. I have known a heavy rainfall in one spot, when 30 miles away there has been no rain. I can show you accounts which will prove that there has been no rain in some districts for the last eighteen months. How, therefore, can we agree with Mr. Russell when he tells us that in those districts the average rainfall has been 10 inches? I have kept a record myself, and I say I have not had an average of 6 inches. Mr. Russell originally estimated it at 15 or 16 inches.

3035. That is a matter we can only decide by getting a large number of private station-holders to send in their reports as you might do. One further question about the Darling: suppose the water were raised by weirs in the manner you speak of, do you think there would be such a scour that the stream might thereby be diverted? No.

3036. You think the banks are of such a nature that the stream would not be able to alter its course? Yes. A private piece of work was done at the junction of the ana-branch with the lower Darling, and it proved satisfactory; a cutting was made from the Darling, and the channel of the ana-branch was lowered, I think, 8 or 10 feet, and that made no difference whatever.

3037. What length was the cutting? I think about 300 or 400 yards.

3038. And that is not scoured at all? No. Originally the water only flowed down when there was a very high flood. A large cutting was made, the squatters defraying the expense amongst them.

3039. Have you sunk any wells at Marfield? I have.

3040. Many? About forty trial shafts.

3041. To what depth do they generally go? From 100 to 300 feet.

3042. What kind of water do you generally get? Salt water.

3043. Have you got any fresh water? I have got one good well and one salt one. I have two wells out of these forty trial shafts—one sufficiently good for stock, but salt; the other a very good one. The rest are all too salt for use.

3044. What is the nature of the drift in which you get the water? It is coarse white sand.

3045. Is it always the same? Yes.

3046. And do you always go through the same class of country down to the water? In some of them there has been a slight change, but there is very little variation. Generally speaking we find clay for a distance of about 60 feet, then after that we get into alternate layers of coarse drift and light sandstone.

3047. Do you find the water in the light sandstone or in the drift? We strike the water in the drift.

3048. Have you tubed any of these wells? I got tired of the trial shaft business, and two years ago I got a boring plant on the ground and have been working away with it. We have not been able to get through the salt water—it seems to be a regular underground river.

3049. Have you in any case found what appears to be an old river-bed? Yes; the old well-sinkers generally say it is an old water-course.

3050. Do you sink these shafts promiscuously, or do you select particular lines of country for them? We pick definite lines of country. We have gone east and west and put shafts down over 2 or 3 miles, where we considered the locality favourable; then we have gone north and south.

3051. What I mean is, do you try to follow any surface indications of underground water-courses? No, we do not. In our country there are no surface indications of water-courses; it is thoroughly dry sandy country, without any indications of water.

3052. Suppose you sink east and west and strike one well here and another there, and you strike what seems to be an old water-course, do you therefrom infer that the whole country in that direction has been a water-course? No, decidedly not. In sinking we always try to find out the nearest points where good water has been obtained, and our endeavour has been to get the same run of underground water when it can be traced; but that means a large expenditure in prospecting for the water.

3053. In how many cases have you struck what has been termed an old river-bed? I do not think in more than three or four.

3054. Not in all? No.

3055. But you get water in all? Yes, we get water in all.

3056. What is the difference between the water generally and the water when you strike the old river-bed? One good well is on what we consider to have been a water-course, but I consider that the next one is not on an old water-course.

3057. Have you any idea what way the water seems to flow in these old water-courses? It seems to me to be making in a south-westerly direction from the north-east.

3058. That would indicate that the direction was from the Lachlan? Yes; I believe that the well I have contains water that has come from the Lachlan in some way or other.

3059. Is there any flow in the well—or did you ever test it to ascertain that? No, I have not tried it for that purpose, but from the extent of the supply I do not think there is any flow. If there were, the supply would be much greater.

3060. What is the supply? About 800 to 1,000 gallons an hour.

3061. In any well have you got artesian water? That is what I have been endeavouring to do, but I have been blocked—I have never been able to get through the layers of sandstone. We generally get through

Mr. C. Fartiere.

8 Jan., 1885.

through two upper layers but get stopped by a third, and this one we have sunk from 25 to 30 feet in solid hard sandstone before giving up.

3062. The water you have got is not artesian? No; that is why I consider it is an old water-course. It is well washed sand that that water goes through; the other water is flowing through the natural soil, and it is salt. This well of ours is the last, and we have been able to trace that water too. It is a strong well-developed creek, and known as the Sandy Creek on the neighbouring runs, and as Crowl Creek further up nearer the Lachlan. On the adjoining station they have a very good well, and after searching considerably we succeeded in getting this well. Our discovery of this well shows the uncertainty there is as regards the position in which the water is found. The men had been engaged under a bonus to get water, and they had tried several shafts in the same locality, but did not succeed. They were then induced to try again, and they put down three more shafts. The third shaft was put down in a thick bit of scrub, when good water was struck. The scrub was cleared away, and it was found that the good water was within a stone's throw of one of the shafts where they had failed to get good water. Had the men known this they would not have sunk the third shaft at that particular spot, and probably not have found the good water.

Sandy Creek, Crowl Creek.

Trial shafts.

3063. You think that this water has been brought down in an old water-course from somewhere further north—that it has found its way northwards underground? I believe, as far as my experience with sinking for water goes, that the water is making a south-westerly direction by an underground course from the north-east.

Direction of underground watercourse.

3064. Have you sunk on your northern station? Yes.

3065. With what success? Better than at Marfield. We have one very good well there, the water of which is fit for domestic purposes, and we have two very good stock wells. We have sunk about six shafts there altogether.

Wells on northern station.

3066. What depth? The good well is nearly 120 feet deep; the others, from 70 to 260 feet.

Depth.

3067. What supply of water do you get? About 600 gallons per hour.

Supply.

3068. Have you any indications there of old river-beds? It is a different soil altogether. We go through a stiff bed of clay, and then get the water in the drift underneath.

Strata.

3069. Where do you suppose the source of that water is? I imagine that it must be water that comes down from Cooper's Creek. There must also be underground water making its way from the Wilson and Bulla in this part of the country as well as the Cooper; the large bodies of water that are collected by the extensive watersheds in Queensland during the summer rains must have an underground drainage passing through the north-western portion of New South Wales, and locally known as the Albert District.

Source of the water.

3070. You consider that it is water from the nearest river, not finding its way in a channel, but generally underground through the drift? Generally underground drift.

Underground drift.

3071. Have you tried to see whether it is artesian or not. No, but I believe it is artesian. I intend to try and get an artesian supply at Marfield.

Artesian water.

3072. *Mr. Donkin.*] What boring apparatus do you use? The Tiffin borer. I believe that boring will be found the means of watering the back country, but the difficulty is to get the proper kind of labour.

Tiffin borer.

3073. *President.*] You want skilled labour? Yes, if I could have got good men I believe I should have got good water long ago, but the difficulty is to get the men. They seem to be right enough as long as they have every appliance at hand, but when they are out in the bush and thrown on their own resources a difficulty occurs—they cannot get on.

Labour difficulty.

3074. What is the cost per foot of putting down a bore? That is according to the kind of men you are able to get. With us the cost has been about 30s. a foot.

Cost.

3075. *Mr. Franklin.*] What is the nature of the difficulty that occurs in boring? You can get through the top soil, the clay, right enough, but after that you generally strike on the drift, and to get through that you require to use piping. You get the piping through the first drift and probably strike some more clay. You get through that right enough, and then very likely get into a sandstone formation. Well, the auger that goes through the drift and the clay must be of a smaller size when it has to work inside the piping. A difficulty then arises; we have to employ different instruments for enlarging the hole to let the piping through, and there is where the jam takes place. I have got through two layers of sandstone, but on getting on to a third layer I have always been stopped, at a distance varying from 120 to 280 feet. It seems that each successive layer of sandstone is harder than the last, and at last it becomes so hard that instead of the tool cutting the stone, the stone cuts the tool and alters its shape. We cannot get the pipes through, although we use great power. We have put as much as 10 tons on to sink them, we have broken things and even killed horses in our attempts to get down. What I mean by having killed horses is to show the difficulty of keeping such work going at times like the drought we have been passing through. I kept on working carting water required at the boring camp, until at last my horses became so poor they died, and I had to suspend operations for the time; that was over twelve months back, and I have not had water sufficient to start the boring work again since that time. I employed one man who brought credentials from India, where he had been employed in well-sinking; he had been also at the Mont Cénis operations. I gave him a high remuneration, and he did not think he would have any difficulty, yet when he attempted to carry on operations he only smashed things and did more harm than good.

Boring difficulty.

3076. What appliances have you for recovering the rods that jam? The machinery will raise the rods itself on its being reversed. We have tugs and an arrangement like a reversed umbrella; you pass that down and it brings the thing up. I am strongly inclined to think that if we get through the salt water a good supply of fresh water will be found underneath, but the difficulties are very great. I thought I should be able to get through it by manual labour, and I went to Ballarat and engaged some of the best miners there. I kept a gang of men going day and night for three months. We went through 40 feet of water and had to give it up—it was coming in like a water-spout.

Raising of rods

Good water under salt water

3077. And you were in a drift? Yes.

3078. What do you estimate to be the value to a large run like yours of any certain means which could be adopted of going to a depth at which reliable water could be obtained—what amount would you voluntarily spend if it could be done at once: the calculation must of course be based on the amount of money which you have lost in these futile attempts? It would pay a man well to pay £1,000 to get a good and certain supply.

Value of a good and certain supply.

3079. If a canal were constructed near to stations like yours, where water is so valuable as to be worth

£1,000

Mr. C. Fartiere. 8 Jan.; 1885.

£1,000 per well, do you think that the station-holders would take the water? They would take it very readily I am sure.

Duration of supply from tanks.

3080. You have a tank with an area of 12,000 yards full of water—that is 2,000,000 gallons—how long will that last? It is a matter of very great uncertainty whether it will last through the summer. I am very anxious about it, and feel sure the supply would not last me this summer if I allowed the stock to use the water direct from the tank, and I have erected troughing and use a 3-inch Tangye steam pump to water the stock; by this means the water is economized to its fullest extent, but the extra plant and labour necessary make a large additional expense to the station.

3081. How many tanks have you that are a failure? I have eight that are empty, and I have three others with about 3 feet of water in them.

Supply.

3082. With all those tanks full you would have a supply of about 20,000,000 gallons? Yes.

3083. What do you consider to be the value of a full dam? It is hard to estimate it. It means the value of the whole place. If any one offered me the value of the run for my water supply I could not take it.

Daily consumption.

3084. What is the daily consumption on the run when it is lightly stocked? It would be 50,000 gallons a day.

3085. Is the surface water at Marfield fresh in all cases? Yes.

Quality of clay-pan water.

3086. *Mr. Donkin.*] Is the clay-pan water fresh? Yes, until it gets down to a certain level. When the water gets shallow it becomes impregnated with decomposed vegetable matter.

Area and depth of Bulla River waters.

3087. *Mr. Franklin.*] What is the approximate aggregate area and depth of the water discharging from the Bulla River? At the narrowest place two years ago when it was in flood it was about a quarter of a mile wide, and there must have been an average depth of about 4 feet.

Length.

3088. What was the length? Well, that point was between two lakes; I suppose it would be a mile long.

3089. That was a sheet of water? That was a sheet of water. I am sure it was a mile. We took the neck between two basins. The average depth would be about 4 feet.

3090. Does the whole of the water disappear by evaporation and soakage? Yes.

Duration.

3091. How long does it remain? About fifteen months, and then it disappears entirely.

3092. *Mr. Donkin.*] How many years did you say you had been on the Darling? Fifteen years.

3093. Were you there when Mr. Gordon visited the Darling to see if dams and weirs could be constructed? I was in the district, but I did not meet him.

Effect of weir on the Darling.

3094. If a weir was constructed so as to raise the water 10 feet, do you think that would cause the stream to cut its way in another direction? No; it would fill a number of natural basins.

3095. If we put a weir across the stream 6 feet in height, do you think that it would cause a scour? No, the Darling has fine hard banks. It is good clay soil. Each one of those lakes has a natural water-course, and they work through lignum, and it generally takes a wide spread, and the overflow water usually moves along in a wide steady stream at a moderate rate. There are not any great or sudden changes in the general level of the Lower Darling country likely to cause any great scour.

Natural weir at Brewarrina.

3096. There is a natural weir at Brewarrina, and we are told that the stream has forced two channels almost as deep as the original bed of the river? I have not been there.

3097. You think that a weir would not force another channel up above? From my knowledge of the river I do not think it likely. I have been down both sides of the Darling, and I know the outlets.

Outlets.

3098. What causes the outlets? Perhaps some peculiarity of the soil at the spot.

Tallywalkas.

3099. What causes the tallywalkas? They are a natural formation—the natural run of the water in times past. When an excessive volume of water came down the river in times past, the tallywalkas formed outlets by which the surplus waters escaped from the river and found their way back subsequently.

Bulgary swamp.

3100. *Mr. Gipps.*] Is the Bulgary swamp surrounded by high land? Yes, there are some ridges of stone higher than the bed of the lake.

Causes of saltness of water.

3101. Do you not think that the saltiness of the water may be attributed to the evaporation, because all water contains salt? I think there is a mineral deposit in the soil. Large cracks frequently appear in the soil, and these take away large quantities of water which finds its way into the sub-soil; but when once the lake is properly flooded it becomes a good holding ground. We do not always find deposits of

Salt deposits.

salt. One of these lakes is known as a salt lake, and you can gather salt on the surface, but on the other lakes there are no indications of salt; they are fresh on the surface, and we find no indications of any saline matter until the water has become low and vegetable matter has begun to decay in it.

Effects of canal from Bulla River.

3102. Then you think that a canal, by diverting the Bulla River, would serve a twofold object—that it would give a supply of water for distribution, and that it would render the soil more prolific by causing a greater rainfall? Yes, we should get a better vegetation. In some of the swamps the salt is so strong

Lachlan River and Golgol Creek.

that no vegetation can grow. If the Lachlan water were dammed and brought towards the Murray, as I have suggested, it would give a vastly increased value to all that country. I feel sure that in times past the water has run down from the Lachlan into Golgol Creek, and if it could do that again it would mean a permanent water supply for all those stations in the intermediate country.

THURSDAY, 15 *JANUARY*, 1885.

Present:—

Mr. BARTON, M.P.,	Mr. GIPPS, C.E.,
Mr. DONKIN, J.P.,	Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E.,	Mr. McMORDIE, B.E., C.E.

W. J. LYNE, Esq., M.P., President, in the Chair.

Mr. Andrew Kelly called in and examined:—

Mr. A. Kelly. 15 Jan., 1885.

3103. *President.*] What is your employment? I am a drover.

3104. In what part of the Colony? I have been on the Lachlan and all over the Colony.

3105. What other parts of the Colony? All about Wilcannia and the Bogan way; from there to Walgett, and through those parts. I have been backwards and forwards at different times to the boundary of Queensland.

3106.

3106. Have you not been a well-sinker? Yes; I sank wells on the Groongong station, and also on the Tippery station. Mr. A. Kelly.

3107. Whereabouts is that? Tippery station is on the Lachlan; it is Mr. James Tyson's place. 15 Jan., 1885.

3108. What number of wells did you sink at Mr. Tyson's station? Only on that we got watering in. We tried two or three more places. Wells.

3109. What depth was that one? I think about 105 feet. Depth.

3110. That was the one you got the water in? Yes.

3111. What quantity of water did you get—how many sheep and cattle would it supply? It supplied a good quantity of sheep in a drought. Supply.

3112. How many? Say about 6,000 a week for about six months.

3113. You mean 6,000 altogether during six months? Yes.

3114. Was the water good? It was brackish. Quality.

3115. Did it rise to any height in the well? Yes. Rise.

3116. About what height? Well, I suppose that from where the stone gave way—that is, where the stone broke at the bottom and the water came in, it might have been 10 feet.

3117. What kind of stone was it? Hard stone. Stone.

3118. Flinty stone or sandstone? Flinty stone. We never got any good water in sandstone, not even on the diggings, unless we came to a hard rock to split at the bottom. I have searched more for water on the diggings that at any other place. Water in sandstone.

3119. On the Temora diggings? Yes. There is good water procurable there; it is good for stock, though not for human use. Water on Temora diggings.

3120. You say you sank several wells in the Lachlan district, but could get water only in one? Yes. You get all the one water in the Lachlan district, but a greater supply in one place than in another. Water in Lachlan district.

3121. But the water is all of the same quality? Yes, except when you get it near the surface. Quality.

3122. And is it your opinion that all the water in that part of the country comes from the same source? It must be, as all the wells contain the same kind of water. Source.

3123. And all brackish? And all brackish. For your own use the water has to be carted.

3124. At what other places did you say you had sunk wells? I sank for water at Temora.

3125. But you said somewhere else? On Tippery and Groongong.

3126. Where is the Groongong? On the Lachlan, about 60 miles from Hay.

3127. Did you get good water in wells there? Yes, one good one; there was one good one at Tippery. Wells at Groongong.

3128. Have you had any further experience in well-sinking in New South Wales? Yes, in the same district.

3129. Where? About Illillawa. At Illillawa.

3130. That is near Hay somewhere? Yes, near Hay, on the other side of the river.

3131. What sort of water did you find there? We sank three different wells.

3132. Was the water good? No; we were not successful in getting good water. Quality.

3133. To what depth did you sink? We sank to various depths; one well was about 80 feet, another 100 feet, and the third about 130 or 140 feet. The three wells were sunk round about in the same district. That was of course keeping pretty close to the river. In the interior it is different altogether. Depth.

3134. But you have not searched for water in the interior? No, but I have searched for water on the surface and in the creeks.

3135. But simply for surface water? Yes; but I believe sufficient surface water could be got for a small supply. We have done that in other places where we have been pushed for water. Surface water.

3136. In the sand, do you mean? In the sand, where there have been some symptoms of a spring. But as soon as ever the water shows itself, it is rushed with stock and tramped in, so that there is no chance of making use of it. But in some places sufficient water is got to supply an immense number of people. Spring.

3137. Did you sink shafts or wells at Temora? Lots of them. Wells at Temora.

3138. Did you ever get any quantity of water? We only got it in one out of ever so many shafts sunk.

3139. What depth was that? I think it was 160 or 170 feet. Depth.

3140. Was the water good? It was not to say good for drinking—it was brackish. Quality.

3141. Was there a good supply? There was a tremendous supply. Supply.

3142. Did the water rise high? It rose as fast as an engine with a 4-inch pipe could throw it for twenty-four hours without stopping. Rise.

3143. Was it an open well or a pipe? An open well at first, and a pipe was put down afterwards. Pipe.

3144. But the object of putting the pipe down was to pump the water out? Yes.

3145. It was not so much for the purpose of consumption that the water was raised as for the purpose of doing the well? No, it was for consumption. Purpose of water-raising.

3146. You were working in that shaft which you sank, were you not? Yes.

3147. Have you had any experience in any other part of New South Wales? I have traversed the country all over. I have not been much pinched for water except at Hay and Temora.

3148. You have never had any experience on the Darling? Only by travelling over the country. I know where the dams are and so on. There was one place up the Darling where we got water in a sort of blind gully; and when we were in Temora we found two or three little springs, from which after a time we got very good supplies of water. On the Darling.

3149. You have no idea what was the source of the water you got at Temora? Yes, I have; I believe it springs out of the mountain. Source of water at Temora.

3150. How far is the mountain away? It is directly on the road as you go to Hillston, about 100 miles distant from Hillston.

3151. Do you suppose that the spring comes from that mountain? It must come from that.

3152. *Mr. Donkin.*] What is the name of the mountain? It is close to Mick's paddock; you may say it is at Temora. There were springs about the place, not far apart. Springs.

3153. Do you think that any amount of water could be got from the mountain? If it was opened out I believe you could. Water from mountain.

3154. Is it all brackish? No, it is very good water; but at some times it is not so good as at others. When you get a large quantity it is brackish, but when a small quantity comes in contact with the air it is good. The same thing happens on the Lachlan. Quality.

3155. Then you say it is better when it comes out first? Yes, when it comes in contact with the air, but after a little time it becomes of a green colour.

Mr. W. J. Farrer called in and examined :—

Mr. W. J. Farrer. 15 Jan., 1885.

3156. *President.*] Are you a surveyor? Yes.

3157. In which district have you been surveying? The district on the Lower Macquarie, from Warren to Mount Harris, back to the Bogan, Nyngan, and down to near Nymagee.

3158. Is it a defined district—is it named? Yes, but I forget the number.

3159. Have you been surveying any length of time? About seven years. I have been in the district more or less for the last nine years.

Macquarie creeks.

3160. What particular information do you wish to give the Commission? With reference principally to the creeks that break out from the Macquarie.

3161. Will you give us any information that will be of service to the Commission in reference to those creeks? It is about seven years ago as far as I recollect that I wrote to the District Surveyor recommending that reserves should be made where the creeks break from the river, in order that cuttings might be made at some future time. The District Surveyor wrote in reply that what could be done in that way would be done; at any rate I was given to understand that he would see to the matter.

Reserves for cuttings.

3162. Was that when Mr. Dagleish was District Surveyor? Yes.

3163. And do you know whether reserves have been made in any instance at the outlets of these creeks? I hardly know, because the outlets of the Beleringa and Gunningba Creeks, in which I took the greatest interest, were just above my district—in Mr. Burton's district. The creeks run through my district, but the places where they break from the river are outside my district.

Cuttings.

3164. And what was your object at this time in writing to have the reserves made? I thought cuttings might be made from the river at some future time, so that the creeks should get water oftener—so that the water might enter the creeks at a much lower flood than they can at present, the banks of the river being higher than the back country.

3165. So that the fall would enable the water to run into the creeks? I think so.

Banks.

3166. But as a rule where the creeks break off from the river is there not an impediment in the shape of a bank? Yes, there is generally high ground near the junction of the creek and river.

3167. And the water only gets into the creeks when the river is at high flood? Yes, very high flood.

Country benefited.

3168. Can you give us any idea as to the country that would be benefited by the several creeks you mention? A large extent of country. I have my county maps here, but they do not give the whole course of the creeks. I should say the country lying between the Macquarie, the Bogan, and the Darling.

Area.

3169. About what extent is that? I cannot form any idea, except by scaling. Probably it is 150 miles in length, by 50 miles in breadth. My idea is that if money is intended to be laid out, weirs with flood-gates should be placed on the cuttings into the creeks. There are some places where I think shorter cuttings might be made, for instance, just about Warren, into the Gunningba Creek, which is about half a mile from the Macquarie in one place. The breaks in some cases are very hard to distinguish, and would require careful survey.

Weirs.

3170. If weirs were thrown across the river as you suggest, would that store sufficient water to have always some at command to let down these natural channels? I think so, except when the river ceases to run. The river does not cease to run very frequently; it has done so two or three times during the last three years. (*Appendix* S.)

Irrigation.

3171. Do you think sufficient water could be stored in any part of the Macquarie to permit of an extensive irrigation in that part of the country? I think so. The Macquarie, generally speaking, is a running river.

Surveys.

3172. Have you carried out any surveys towards the head of the Macquarie? No; my district only extended from about 4 miles above Warren to 30 miles below.

Natural basins.

3173. In the part of the country you are acquainted with are there any natural basins where water could be stored? Do you mean in the river?

3174. In or near the river? Yes, I know of one.

Large lagoon.

3175. Where flood waters could be stored? I know one large lagoon about 5 miles from Warren.

3176. Is it at a sufficient elevation to command the lower country? I do not think so.

Irrigation.

3177. Then you do not know any spot sufficiently high for the water to command the lower country for the purpose of irrigation? Mounts Foster and Harris are near the river, and if water were raised some country might be irrigated from them by gravitation, but the amount of land would be very limited.

3178. Have you been surveying about the Macquarie marshes? No.

3179. I think I understood you to say you had been down as low as Nymagee? Yes, my district extends to within about 9 miles of it.

Nymagee.

3180. Have you been surveying about Nymagee? Yes; lately I have been within about 9 or 10 miles.

Nature of country.

3181. What is the nature of the country between the Bogan and Nymagee? It is pine and box forest, undulating country, a little sandy perhaps.

3182. What is the elevation—have you any idea? I have no idea.

3183. Is the country at all rangy? In places it is; near Nymagee it becomes rangy, and towards Cobar it becomes rangy, and it is undulating in several parts.

3184. Can you give approximately the height of the country rising from the Bogan in that direction? I am afraid I cannot.

Supply from the Bogan.

3185. Do you think it would be possible, without going to very great expense, to convey water from the Bogan down through that country? I do not think it would; the Bogan itself is too poor a source of supply.

Wheat-growing land about Cobar-Nyngan Road.

3186. I only mention the Bogan in connection with the level of the country—water could be brought into it from other places? I am afraid the country rises too high. The levels taken in the survey of the proposed Cobar-Nyngan railway will throw light on this. If the West Bogan country could be irrigated the gain would be immense, as very much of the land would grow grain, and especially wheat, splendidly. The best looking (for wheat-growing) land that I ever saw lies around the middle Government tank, on the Cobar-Nyngan road. The ascent is very gradual. My idea is derived from Mr. Kinnear, who told me about the frosts they have at the overflow station.

Creeks benefited by cuttings.

3187. For what purpose did you bring your county map? Just to show where the creeks break out from the river, so as to give an idea of what creeks would be benefited by cuttings from the Macquarie. They are the Beleringa, Gunningba, Duck, Crooked, and Mara Creeks; these will all be benefited.

3188. Are these creeks dry now? I think they might be considered as virtually dry. There was one waterhole in the Gunningba Creek containing water, which had been collected by means of drains from some hard ground on the plains; some of the best waterholes however have little or no water in them. Mr. W. J. Farrer. 15 Jan., 1885.

3189. Then, supposing the water were diverted in the manner suggested, you would not expect that a constant stream would be sent down, but only when required to fill up the tanks and dams along the creek? Yes.

3190. But you do not make any suggestion as regards irrigation? No, I cannot make any suggestions; I think the country is too flat, unless expensive pumping machinery were used; and I consider that the extraordinary richness of the land would warrant the expenditure incurred in a trial. I doubt if the ground on the bank of the river is so much higher than the adjacent ground further back as to allow gravitation to be of much assistance. Irrigation.

3191. Is there anything else you would like to say? There is a suggestion of mine with regard to storing water at the crossing of rivers. I have an idea that, instead of making bridges, over-shot dams should be constructed as roadways across such dry rivers as the Bogan. At Nyngan the water is stored by means of a dam. I surveyed the road from Cobar to Nyngan some five years ago, and in my report on that road I recommended that instead of making a bridge over the Bogan an embankment should be made to carry the traffic over. The matter was ridiculed at the time in the Roads Department—in fact "nonsense" was written on the papers when they were sent back to me, but afterwards the railway contractors for the extension, when they were in a difficulty about making a temporary bridge over the Bogan to carry their rolling stock across, made an embankment for the purpose, though they spoiled it by making an artificial cutting for a get-away for the water. Still I think water might be stored in that part of the country by constructing dams at the crossing-places of the rivers and creeks instead of bridges. (*Appendix* S.) Storage of water at crossings of rivers.

3192. Whenever there is a necessity for a bridge you would make an embankment? Yes, some sort of overshot dam. Overshot dam.

3193. You would do that as a matter of saving expense? Yes, and to save water for the use of the traffic.

3194. You think that by making a dam there would be a great saving of public money? Yes. I think those sort of dams would be well suited to that country. My idea was that the overshot dam should be paved with blocks of wood or something of that sort, and made with a depression in the middle. In times of heavy flood the traffic might be stopped for a day or two, but that would be of comparatively little consequence. Saving of money.

3195. Do you know anything of the country between the Macquarie and the Castlereagh? Yes, I have been across there once. Country between Macquarie and Castlereagh.

3196. Is it level country? Yes, as far as I recollect.

3197. Have you been out further than the Castlereagh? I have been on the road to Coonabarabran and Coonamble.

3198. And as far as you have been the country is almost flat? No, when you get near Coonabarabran you get into the Warrumbungle ranges. Warrumbungle ranges.

3199. But taking a straight line from Warren to the junction of the Gwydir and Darling—what is the character of the country there? The part which I know—that between the Macquarie and Castlereagh Rivers—is flat.

3200. And there would be no difficulty in taking a canal through there? I think not.

3201. *Mr. Barton.*] How often are those creeks that you have mentioned as running out from the Macquarie running—do they run every year? It is five years since any of them ran. Water-flow in Macquarie creeks.

3202. And supposing that a weir was put in the Macquarie, how often do you suppose the water would run through? As often as the water was let into them. They would be under your control, and you could let the water in when you liked.

3203. Do you know what height you would have to put a weir in the Macquarie to make the water run down the creeks? Almost the full height of the banks of the river. Height of weir in the Macquarie.

3204. What is the height? I cannot tell you.

3205. *President.*] But that would not be so if there was a necessity for a cutting, and if there is a necessity for a cutting the water would run out before it got to the top of the bank? In that case it would not be necessary to go to the top of the bank.

3206. *Mr. Barton.*] What height do you think the banks are? I should think between 20 and 30 feet. Height of banks.

3207. And how far do you think the water would be thrown back in the Macquarie by a weir? I cannot tell; I should think about 4 or 5 miles.

3208. *Mr. Franklin.*] Do you think there is a fall of 4 feet in the mile in the river—that is a very great fall? I doubt if there is. In that case the water would be thrown further back. Fall of river.

3209. Have you any reason to believe that there is a lateral drainage from the river—does the water fall rapidly? No, not rapidly, but it does fall. The creeks are supplied from the flood-waters of the river.

3210. Then the creeks flow away from the river? Yes.

3211. On either side, or in one direction only? In one direction only. Direction of flow in creeks.

3212. In what direction is that? To the north-west.

3213. Those creeks run a considerable distance, do they not? Yes. They all break from the river.

3214. Do you know whether the fall is great enough to allow a cutting in the bank of the Macquarie to carry the water of ordinary freshes into those creeks? I do not know.

3215. It has never been tested instrumentally, I suppose? No.

3216. And do you think it of so much importance that the levels should be tested by this Commission? I certainly think so. Levels.

3217. You are not aware whether any levels have been taken for the purpose by private enterprise? No, as I said before, it is seven years ago since I wrote to the District Surveyor suggesting that reserves should be made to enable the Government to make cuttings at any future time.

3218. *Mr. Donkin.*] You suggested that where the off-takes occur the channels should be deepened and a weir put across the river? Yes. Weirs and channels.

3219. Is it your opinion that if a weir were put there it would cause the river to make a new channel? No; the weirs would have flood-gates, which would only be closed when you wanted to let the water into the cutting. New channels. Flood-gates.

3220. But if any obstruction at all is put into the river, do not you think it would cause it to cut a new channel? No, I do not think so.

Mr. W. J. Farrer. 15 Jan., 1885.

3221. Do you know any dams across the Macquarie? No.

3222. Do you know any dams of the Bogan? Yes.

3223. Is the river cutting a new channel there? Yes, it is.

uddall dam. 3224. Not in the case of the Muddall dam? Yes; there are embankments put across the cuttings in all directions.

By-wash. 3225. But perhaps a by-wash has been cut? I cannot say whether there has or not, but I think not.

3226. But you think that a weir with a flood-gate in it would prevent that? Yes; there should be two flood-gates, one in the weir and the other in the off-take.

Muddall embankment. 3227. How many miles back does the Muddall embankment throw the water? I do not know.

Dams instead of ridges. 3228. You say that you suggested to the Government that instead of building expensive bridges they should construct dams? Yes.

3229. Do you think that would be necessary? Yes, but the best mode of making the dams would have to be found out.

3230. Is not the fact that the Muddall dam has stood fifteen years some guide? There has been no traffic across that.

Effect of traffic. 3231. *President.*] Traffic would rather strengthen it? Yes, but those lines of traffic do not cross where there are good natural get-aways. Of course, when a station dam is made, the site is chosen for the get-away.

Height of Nymagee. 3232. *Mr. Donkin.*] You do not know the height between the Bogan and the Nymagee: Nymagee is on the fall of the Lachlan is it not—you cross the Dividing Range just before you get to Nymagee? Yes, I think it is on the fall of the Lachlan.

Height of Dividing Range. 3233. Do you not know what the fall of the country is up there—would you say that the Dividing Range was 1,000 feet above the sea? I should think it was.

3234. That would make it 400 or 500 feet above the Bogan at Nyngan? Yes, the Dividing Range, of course, varies in height.

Nature of country. 3235. It is undulating granite country, with rough hills and bases, is it not? Yes.

3236. Have you been to Eremeran? No, but I have seen the Dividing Range as it goes through the Melrose and Walker's Hill Runs, but I was never on the Eremeran Run.

3237. Have you been west of Cobar? No; I have been as far as Cobar, but never west of it.

Crowal Creek. 3238. Is the country at Cobar as high as at the head of the Crowal or Crowie Creek? Those Crowal or Crowie Creeks are rather mixed. The last thing I did was to survey a creek called the Crowal Creek, and it is quite distinct from what is called the Crowal Creek a short distance away.

Diversion towards Nymagee. 3239. Do you think that water could be taken from Nyngan across the range to Nymagee through that country? I do not think so.

Construction of dam. 3240. *Mr. M'Mordie.*] Will you explain a little more clearly how you propose to make an over-shot dam to serve the purpose of a bridge? Well, my idea was that the over-shot dam should be paved, or something of that sort.

3241. But you would have the same quantity of water flowing over the dam that would otherwise flow in the bed of the river? Well, the rivers across which I propose to put the over-shot dams flow very seldom.

3242. And therefore a bridge would not be required for purposes of traffic? Well, the rivers are flooded at times.

3243. But would not the over-shot dam be flooded at the same time, and therefore would it not fail to serve the purpose of a bridge? It would serve the purpose of a bridge, although the traffic might be stopped for a few days.

Bogginess of rivers. 3244. But at the time the bridge is required the over-shot dam would not serve the purpose of a bridge? But there is this to be considered,—that the beds of the rivers become so boggy, and it is the bogginess that is the great drawback.

3245. Then the purpose of a bridge could be served by paving the bed of the river? But then you would lose the advantage that I propose from the over-shot dam, viz., the storage of water for the use of the traffic.

3246. *Mr. Donkin.*] When there is a big flood in a river, even if there is a bridge, you cannot get to it? If the river ran at all the over-shot dam would be filled, and perhaps a small stream would trickle over it for a short time.

3247. *Mr. M'Mordie.*] There would be the same disadvantage with an over-shot dam as with the water running over the bottom? Yes, at times of high flood.

Depression in centre of dams. 3248. *President.*] But in the cases you speak of, supposing that a dam were placed across a river and an indentation paved in the centre, the dam would throw the water a considerable distance over the country around before any went over the dam? Yes, but that would depend on the height of the depression in the centre.

Places for dams serving as bridges. 3249. Do you know of any case where the building of a dam to serve the two purposes of a dam and a bridge would be serviceable—in the Macquarie, or the Bogan, or any of the creeks? It would have done at Nyngan; it would do where the travelling stock route crosses the Bogan at Buddabadah.

3250. Is not the traffic over the creeks and almost dry rivers frequently stopped for months on account of the beds being boggy? It is not stopped altogether, but heavy teams have great trouble in getting across.

3251. And is the object of building a bridge to get across at flood-times or at ordinary times? Both.

3252. But more particularly which? At ordinary times.

Bridge at Dandaloo. 3253. *President.*] I may mention that at the present moment there is an application for the building of a bridge at Dandaloo, on the Bogan, and the only water there is water backed up by a dam 5 miles further down the river. The bridge is applied for because the bed of the creek is so boggy that the teams cannot cross. I mention this in support of what Mr. Farrer suggests. It is not for the flood-water that bridges are required, but the bed of the Bogan is so boggy that teams cannot get across at all.

3254. *Mr. M'Mordie.*] In that case the proper course is to form a solid roadway through the bed of the river.

Watersheds. 3255. *Mr. Gipps.*] Are there any defined watersheds to these creeks? No, I do not think there are; there is a watershed on the west side of the Bogan, but not on the east side.

Outcrop of rocks. 3256. Is there any outcrop of rocks in the beds of the creeks? None that I am aware of.

Mr. W. J. Farrer. 15 Jan., 1885. Steam scoop.

3257. *President.*] Is there anything further you would like to explain to the Commission? Not long ago I went to see a steam plough and scoop at work near Nymagee, making a tank on the Nymagee and Nyngan Road. One thing in connection with that plough and scoop which had been overlooked was pointed out to me. The scoop when full of earth represents a weight of 10 tons, and when dragged over the ground makes it almost like rock and very hard to pick. The sides of the tank however were not the exact batters required by the Government, and so the contractor had to pick away the hard ground to make the batters according to the specification. Then in consequence of the hard earth being picked away the water would soak through the ground to a depth of 5 or 6 feet, and so the tank would be spoiled to a certain extent. One of the great advantages of the steam plough and scoop is that it hardens and compacts the batters, and prevents the water from soaking away.

3258. *Mr. Donkin.*] Is the tank full now? No; the contractor had not finished it.

Best ground for water reserves.

3259. He was not making a circular tank? No. There is one thing with regard to work in my district. I have had a great deal to do with applications for water reserves, and my idea is that the best water reserves that can be made are the areas of hard red ground.

3260. *President.*] It is good holding and catching ground? Yes. I have had to report on numbers of applications for water reserves on areas that are totally unfit for holding water; people have applied for water reserves in cowls where the water would soak away at once—they would never retain water.

Cowls.

3261. *Mr. Donkin.*] There is a large cowl at Canonbar, is there not? There are cowls about Canonbar—I do not know of one at Canonbar.

THURSDAY, 22 JANUARY, 1885.

Present:—

Mr. DONKIN, J.P., | Mr. GIPPS, C.E.,
Mr. FRANKLIN, C.E., | Mr. M'MORDIE, B.E., C.E.

F. A. FRANKLIN, Esq., C.E., IN THE CHAIR.

Mr. M. A. Maclean called in and examined:—

Mr. M. A. Maclean. 22 Jan., 1885. Lake Cargellico.

3262. *Chairman.*] You are in the Government Service? I am a draftsman in the Survey Department.

3263. Are you a resident in the back country of New South Wales? No, I am a resident in Sydney.

3264. What kind of information do you desire to give to the Commission? It is with reference to what I may call an artifical lake—Lake Cargellico, near the Lachlan River.

3265. On what part of the Lachlan? Near Euabalong.

3266. How far below Condobolin? About 60 miles. I spoke to Mr. Gipps about it, to show how easily water might be conserved at that particular place. The lake is really a submerged plain, and fills during flood in the Lachlan. By a small lock the water is prevented from receding or running back into the Lachlan.

Dam.

3267. There is at present a small lock there? Yes, or small dam.

3268. Is there a dam across the Lachlan, in the vicinity of the lake? No, not across the Lachlan. The dam is across a creek which connects the lake with the river.

3269. How far from the entrance into the lake—how far down the river is the nearest dam? The dam is across a creek which connects the lake with the river; I do not know how far it is from the nearest dam.

3270. *Mr. Donkin.*] Have you seen a dam about there? No, I have never seen any dam in the vicinity.

Supply.

3271. *Chairman.*] At about what level of the Lachlan is this lake supplied in freshets of the river? In ordinary floods.

3272. When the water is within the banks? Yes.

River level.

3273. And what rise of water would that be above what is called the summer level of the river? I believe a little over 12 feet rise would throw water into the lake.

3274. After a flood in the river has subsided, does the water run back from the lake, leaving it shallow again? Yes, most of the water would run back if it were not for the lock.

Silting.

3275. Do you know whether there is a large amount of silting near the position of this lock? Speaking from memory, I think not. The water from the lake goes through marshy country before it gets to the lock. The lake is about 2 miles from the Lachlan River.

Regulation of lock.

3276. Need the lock be regulated to let the water back into the river? Yes, it is done periodically, in order to get fresh water during any flood.

Notice of flood.

3277. I suppose there is timely notice of any flood? Yes.

3278. At whose expense was the lock and the entrance to the lake made? At the expense of the lessee of the run.

Permanency of supply and area.

3279. Could you give any information as to the permanency of the water and its area? The area of the lake is about 10 square miles, with an average depth of about 11 feet. Strictly speaking it is a chain of lakes—Cargellico, Manie's, and Maria's, Cargellico being the largest and deepest.

Natural channels.] Levels.

3280. Are these lakes connected by natural channels? Yes.

3281. How are they with regard to levels—do they draw from one to another? Yes, from the back lake (Maria's), towards the river.

Distance between lakes.

3282. And what is the distance of the several lakes from each other? They run almost into each other—there is no definite channel between them.

3283. I suppose you are acquainted with the prevailing levels of that locality? No.

Position of lake.

3284. Can you say whether the water could be distributed by gravitation from the lake? I think not. The lake is in the bed of a low-lying plain.

Raising of level of lake.

3285. Do you think it possible that the level of the lake could be raised by artificial works above the level of the surrounding country? Yes, I think it could.*

3286. But only when the entire country was flooded—now it is filled only when the river is full? Yes; the lake could be raised to a higher level by embankments constructed around it.† 3287.

---

* NOTE (*on revision*):—I misapprehended this question. The answer is *No.*—M.M.

† NOTE (*on revision*):—I took this question, with the preceding one, to refer to keeping the lake at a higher level than usual, which can be done by raising on the dam across the creek.—M.M

Mr. M. A. Maclean.

22 Jan., 1885.

3287. But suppose these improvements were made, I do not see that any one but the lessee would benefit by it? There is a mining township on its banks, and a considerable number of selectors around.

3288. Can you give the Commission any further information with regard to the lake, to show that the water could be made available to others besides the lessee, or how the storing capacity could be increased? I believe the Department of Works intends to take charge of the lake, and regulate the supply of water by flood-gates and a proper dam. The present dam is a very primitive one, which cost about £200, although it ensures the lessee a valuable supply of water.

Regulation of lake by flood-gates.

Depressions on the Darling.

3289. Do you know any other depressions near the Lachlan which could be treated in that way if inlet cuttings were made? I do not think there are any others on the Lachlan. There are many depressions on the Darling, about Menindie.

Natural inlets.

3290. They have no natural inlets? No; there is in the river sufficient water for stock, and the land-holders prefer to use the beds of these lakes for pasturage.

Effect of droughts.

3291. I suppose the portion of the Lachlan about Lake Cargellico has suffered as much from drought as other parts of Riverina? Yes, very much. I believe that the lake is very low now, although there is water in it.

Evaporation.

3292. Is that owing to the consumption for stock? Not only that, but also to evaporation.

Soakage.

3293. And soakage, perhaps? And soakage.

3294. Do you know what means the lessees in the vicinity of this lake use for getting water for stock? Mostly tanks, back from the river.

Tanks.

3295. How are they formed? By excavating in depressions.

3296. The country is level? It is undulating in the vicinity of the lake.

Nature of soil.

3297. Is it good holding ground where the tanks are made? Yes; a red clayey soil.

3298. I suppose you do not know anything about the water derived from the wells about there? No.

Dam-making.

3299. Did you notice the style of dam-making, and what mode is adopted of protecting the water from winds? No.

3300. Did you notice the tanks particularly? I did not inspect them generally; those I inspected were merely excavations.

Disposal of soil.

3301. How was the excavated soil disposed of? By embanking, so as to make a dam as well as a tank.

Depressions near Menindie.

3302. Can you give us any information as to depressions on the Darling, similar to those you have been speaking of? There are similar depressions near the Darling, but much larger. Close to the town of Menindie there are several of them.

Value of pasturage in lakes.

3303. But you say the people there do not encourage the flow of water into them? They do not take steps to retain the water in them, as they consider the pasturage the depressions afford is more valuable.

3304. To keep them full of water would then do them permanent damage? It might at present. At this time the grass is more valuable than the water. We are taking steps to reserve all these areas.

Weir across Lachlan.

3305. If a weir were put across the Lachlan, below Cargellico Lake, would it throw the water far up in the Lachlan? I cannot say.

3306. You do not know the slope of the water? No.

Effect of weir.

3307. If a weir were raised 4 feet, you do not know how far the water would run back? I have no idea.

3308. Have you any reason to believe, from what you know of the flow of the Lachlan, that the flank of an ordinary earthwork dam would be turned if one were put in there; or would the river be diverted by the obstruction? I was only on one side of the river at a particular spot, and I cannot say.

Lakes near Menindie.

3309. Have you any further information you wish to give to the Commission? There is a small lake close to Menindie, with an area of about 26 miles; indeed, there are two lakes close together, named Pamamaroo and Tandore Lakes.

3310. How far is the lake you speak of from Wilcannia? It is close to Menindie—about 10 miles away I think.

3311. Up the river? Yes.

3312. It has been surveyed to scale as shown by you? Yes, in part.

Area.

3313. What is the area? About 26 square miles.

3314. Have you any memorandum of the average depth? No.

3315. It is close to a bank of the river? Yes.

Inlet.

3316. Is there an inlet at that place? There is an inlet, with apparently sound ground, which the travelling stock route crosses.

3317. What is the length of the inlet? About 2 chains or a little more.

Effect of drought.

3318. Do you know whether the water has remained in the lake during the late dry seasons? I believe it has not.

3319. It is perfectly dry now? Yes.

3320. You do not know the mean depth of it? No.

Dam.

3321. Are you aware whether any dam has been made to keep the water constantly in this depression? I believe not in the case of the one near the Darling.

3322. From your observation you do not know that it is practicable? No.

3323. Can you put in as an exhibit the tracing you produce? No, but I can send you copies of it. (*Appendix* T 1.)

3324. Have you any further information you wish to give? I think not.

Bank of Lachlan.

3325. *Mr. Donkin.*] Did you notice the depth of the bank of the Lachlan at Lake Cargellico? It is over 30 feet.

Slope of country.

3326. *Chairman.*] Do you know if we can ascertain whether there is a point at a low level, so that the water could be diverted from the lake to the adjacent country? No, I think the country slopes towards the lake.

3327. If you are in doubt, could we get the information from the Survey Department, or from the officer in charge of the district? Mr. G. W. Walker, who made surveys round the lake, might give some information.

3328. *Mr. Donkin.*] In what year were you at Lake Cargellico? In 1880.

3329. Have you ever been at Lake Cowal? No.

Other lakes.

3330. You have not seen any of these other lakes on the Darling? No.

3331. They are shallow as compared with Lake Cargellico? Yes.

Catchment.

3332. Next to Lake George that has the best catchment—better than any in the western district? Yes, though it is quite an artificial lake.

Length of dam.

3333. *Mr. Gipps.*] What is the height of the dam across the creek connecting the Lachlan with the lake? Nearly 14 feet.

3334. What is the height of the highest flood at this position of the dam? About 5 feet above the dam. Mr. M. A. Maclean.
3335. What is the dam constructed of? Of clay, stakes, and boulders.
3336. What is the length of it across the creek? About 150 feet, I think. 22 Jan., 1885.
3337. What is the character of the country—is it rocky, and what is the surface soil in the vicinity of the lake? I cannot remember; I do not think it is sandstone. Character of country.
3338. Is the soil impermeable? Yes; red clay.
3339. When the water in the lake is low, is it sweet or brackish? That I could not say; I have tasted the water, but that was when the lake was full. Quality of water.
3340. *Chairman.*] What is the name of the lessee? Mr. Mackellar. The elder Mackellar died last year. The son would be able to give you information. Lessee.
3341. What is the name of the run? Wooyeo. Name of run.
3342. *Mr. Gipps.*] You say the lake is in a basin: is there a range of hills on all sides of it—would the longitudinal section be long, or how long would be the longitudinal section through the hills—is it a regular range of hills? Yes, on two sides. I do not know what the longitudinal section would be; it would be some miles. Range of hills.
3343. Would a tunnel enable the water to flow on to the surface after crossing the range? I think not—the lake is so depressed. Tunnel.
3344. *Chairman.*] You are not aware of the existence of any levels of the land on the other side of the range showing the line of the fall of water? No, I am not aware of any. Levels of land.
3345. You are still in the Survey Department, are you not? Yes.
3346. Can we get copies of these plans you have put in to-day? Of course, with pleasure. Plans.
3347. Can you tell us what you will send in as appendices to your evidence? Locality map of Menindie, showing lakes, tracings of sections and cross sections and sketch of creek from Lake Cargellico to Lachlan River; I will also show the areas of these lakes as far as we can ascertain them. (*Appendices* T 2 *and* T 3.) Appendices.

Mr. M. Campbell Laingtree called in and examined:—

3348. *Chairman.*] You are a resident in the district of Cobar, or near there? Yes. Mr. M. C. Laingtree.
3349. You are engaged in pastoral occupations there? Yes, near Cobar.
3350. I suppose you are well acquainted with the district and its resources? I know it very well, having travelled over it. 22 Jan., 1885.
3351. What is its present condition? Its condition just now is very bad—the country is exceedingly dry. Country near Cobar.
3352. What provision is made there for the water supply of stock? We make tanks; on some runs between Cobar and Bourke they have wells also. Tanks.
3353. Do you find that the tanks on the present system of construction provide you with permanent water? Yes. If you make tanks 15 feet deep with dams on the lower side, it lasts longer than the grass does, we find. Supply.
3354. With regard to the losses of stock, do you estimate that you lose more for want of pasturage than you lose for want of water in that district? Altogether I think we lose more for want of pasturage. Previously, stockowners depended on the gilgais, and lost a good deal of stock for want of water. Causes of loss of stock.
3355. With your present arrangements how long could your stock exist without the ordinary rains—for a year or two? I do not think our water supply would have failed if sufficient rain fell to make the grass grow. There would be occasional thunder-storms, and we make long drains, which is the secret of keeping the tanks filled with water; almost every drop of rain that falls by this means goes into the tank. Duration of supply.
3356. They are open V-shaped drains? They are open flat drains made with plough and scoop, about 6 inches deep, and from 3 to 8 feet wide, with the stuff placed on the lower side forming an embankment. They are contour drains with the least fall, cut to get the greatest length. Shape of drains.
3357. Before making the drains do you make an instrumental examination of the ground? Yes, we always lay the drains off with the level; we make a regular fall of about 1 inch to the chain, sometimes 2 inches if there is gravelly ground. Laying of drain.
3358. If you had a permanent head of water, would it pay the pastoral tenants to make these drains a considerable distance through their runs? I think they would pay.
3359. I think you said you did not take levels in laying out the drains? Oh yes we do.
3360. For the supply of the tanks? Yes; but we only do so in order to get the longest drain we possibly can get. By laying a drain 1 inch to the chain, we calculate that is about the smallest fall we could give it to prevent the water being absorbed in its course; when there is loose ground you cannot get a smaller fall. Fall of drains.
3361. What is the extent of your run? 60,000 acres—one block. Extent of run.
3362. What do you estimate your permanent water supply to be? About 45,000 cubic yards. That is the actual excavation; but there are dams round the tanks which conserve a supply equal to three times that amount. Water supply.
3363. Has the water ever risen above the level of the excavation? Yes. Rise of water.
3364. To what height? 5 and 6 feet.
3365. Do you find the embankments retentive? We always make them so by constructing them in layers, and consolidating the material by travelling drays over it.
3366. Has there been any great evaporation of the water above the surface? I cannot say; but where there is a new tank I suppose the principal loss is by absorption. Evaporation.
3367. You have never kept records of the loss by evaporation? No, though the loss by that means would no doubt be greater when the water spreads over a large surface.
3368. That is, the larger the surface exposed the greater would be the loss? Yes.
3369. Have you any wells on your run? I put down one 110 feet but got no water; it was in a shallow watercourse where I sank the shaft. Well.
3370. What distance was that from the tanks? From the nearest tank it would be about 2 or 3 miles.
3371. You have no reason to believe that the water you have been turning into the tanks forms an underground supply? No; the bottoms of the tanks are impervious to water. Impervious bottom of tanks.
3372. What is the nearest well to you where you were successful in discovering water? I believe there is permanent water 10 or 12 miles from the shaft I sank, but I do not know that as a matter of fact. Permanent supply in well.

Mr. M. C. Laingtree. 22 Jan., 1885.

3373. What are the general features of the country about Cobar—is the country ridgy or level? It is undulating about Cobar.

3374. Does the country seem to fall from Cobar in every direction? Yes, especially towards the Bogan and Darling.

3375. You do not know the height of Cobar above the Darling? No.

Fall of country near Cobar.

3376. In each way from Cobar does the country fall so as to afford drainage—does it fall in the direction of the Darling, or parallel with it? I think generally in the direction of the Darling. The country between Cobar and Nyngan is comparatively flat—for 30 miles from Nyngan towards Cobar the country is almost absolutely flat.

Nature of country.

3377 What is the nature of the country from Cobar in a direct line to the Bogan? Undulating about Cobar, and flat for about 30 miles from the Bogan.

Direction of drainage.

3378. What is the direction of the water drainage from Cobar? Towards the Darling.

Diversion from Bogan towards Cobar.

3379. Do you think the water of the Bogan could be conveyed any distance towards Cobar in time of flood? I should think it could be conveyed in that direction for 15 or 20 miles.

Dry channels.

3380. Do you know of any dry channels existing there? I do not know any ana-branches, if that is what you mean.

3381. Or dry creeks? I do not know of any on the Cobar route, or between Nyngan and Cobar.

Shape of tanks.

3382. Which do you consider the best shape for tanks in your part of the country? For watering stock we always make them square on the top, with side slopes of 3 to 1 all round; but to conserve water and have as little evaporation and absorption as possible we make the slopes 1½ to 1; the greatest depth we

Depth.

give is 20 feet. I have not got a tank 20 feet deep, but the adjoining runs have them that depth. We usually go down until we reach the rock. The average depth of tanks in the Cobar District is about 13 feet.

Watering stock.

3383. In what manner do you water the stock? We allow them to water themselves.

Slope of tanks.

3384. What slope is there at the approach to the tank? 3 to 1, or 6 to 1 on roadway of tank.

Roadways.

3385. You do not provide an apron to protect the slope? No; we sometimes make the tanks with two roadways at each end, the slope of the roadways being about 6 to 1.

Stock.

3386. What kind of stock is it in that part of the country? Sheep.

Aprons.

3387. Do you not find it objectionable to allow the sheep to go into the water? Yes, it would be better to keep them out; but everything is quite new in that district. I have no doubt that in course of time aprons will be laid in the shape of wooden gratings, so that the sheep can water on them.

Waste of water by fleeces.

3388. Do you not think that the fleece would carry away as much water as the sheep can drink? Yes, if the sheep went deeply into the water, and they often do; but as they generally drink without wasting a great deal of water we have not yet taken steps to save loss in that way.

Troughing.

3389. As a general rule it would be better for full fleeced sheep not to go into the tanks? It would be better that sheep should not go into the water, and it would pay to have troughing at each of the tanks; up to the present, however, there has been nothing but outlay with very little return since the Cobar

Want of grass.

country was occupied.—the losses have been great for want of grass.

Pumping from tank

3390. If there was a probability of losing water from drought, would it not be better to adopt the system of the Government in pumping from the tank? I think so.

3391. *Mr. Donkin.*] Have you had any experience in water conservation in any other country? Only in Victoria, where I was occupied with water supply for some time.

Water conservation in the west.

3392. Can you suggest any general plan for water conservation in the western district? If the Government determine to lay out any sum of money in a water supply, overshot dams might be put on the flat or flood creeks to throw the water back so that it might be conveyed from the flooded parts of the country.

Creeks and depressions. Overshot dams.

3393. There are several of these creeks in this district? Yes, and all run towards the Darling. I do not know of any ana-branches of the Bogan, but I should think plenty of depressions could be found if overshot dams were made.

System of dams and wells.

3394. Do you think that money would be better expended in conserving water on these flood channels and throwing it back than in sinking wells? I think the system of dams would certainly be the best, because the dam fills naturally, whereas the water from wells has to be brought to the surface, except in the case of artesian wells.

3395. You know of no artesian wells in that district? No.

3396. What distance could water be thrown back with a dam 6 feet high? 3 or 4 miles.

3397. And you recommend a system of over-shot dams? I do.

Loss of stock.

3398. Then from your experience in the Cobar district you have not found stock to die for want of water? I have known it to be the case, but only when the tanks were new and not filled before the dry weather set in.

3399 Do you think that the present means adopted of conserving water is sufficient to keep stock alive, and that the deaths occur not from want of water but from want of grass? I think we want more water—many of the tanks have not been filled—but generally speaking the stock die for want of grass, because

Water supply from Darling.

the water in the tanks outlasts the grass. I think the Darling is the place where the greatest water supply could be obtained; there are ana-branches there, and by means of over-shot dams these ana-branches could be kept continually full without interfering at all with the water in the river, because they would be filled at flood-times, and the river would flow over them. The ana-branches would be filled without lessening the water in the river.

Springs.

3400. Do you know of any natural springs in that country? No. When I first went there I found under the hills what I thought to be springs, but I subsequently discovered that they were simply soakages, stopping when the rains stopped.

Gilgais.

3401. Is there any natural water between the Bogan and the Darling? Only small gilgais. There is no permanent water in the Cobar district that I know of, unless artificially made.

Expenditure on water conservation.

3402. *Chairman.*] Can you give anything like an average of the expenditure for water conservation on the runs there? I should think if 15d. to 17d. per yard were allowed for all the excavation that would give some idea, but I do not know what the gross amount would be.

3403. But could you not give approximately the number of cubic yards excavated for the conservation of water for each 10-mile block, say? I should say about 40,000 yards for each 10-mile block. If properly distributed that would be about £3,000.

3404. The water is worth the interest on that money, at 6 per cent, I suppose? More than that—money cannot be better laid out than in providing water for the back country.

3405. You think that some system of keeping a permanent supply of water by payments at that ratio would be supported? Certainly. Mr. M. C. Laingtree.

3406. *Mr. Donkin.*] From your general knowledge of this part of the Colony do you think a system of irrigation could be adopted? Not in the Cobar district. Conserving water would pay, but not irrigation. 22 Jan., 1885. Irrigation.

3407. Could it be carried out? I think not; I am almost sure that a system of irrigation could not be carried out except at an extravagant outlay which would not admit of its being a commercial success.

3408. *Chairman.*] Do you think it absolutely necessary to finish off your tank with angles neatly cut? No; we simply lay them off square for convenience in measurement. The men in that district understand making them square; any other shape would cost more. Angles of tanks

3409. Do you think a square tank is preferable for stock? No.

3410. *Mr. Donkin.*] In Riverina they make merely a basin with plough and scoop? Yes; but I do not know how by this means they dig out a circular tank. I should think it would be a more expensive process than in making a rectangular tank. Still, I think a circular tank is preferable to a square tank, as the stock can get round it. Circular tanks.

THURSDAY, 12 *FEBRUARY*, 1885.

Present:—

Mr. DONKIN, J.P., Mr. GIPPS, C.E.,
Mr. FRANKLIN, C.E., Mr. MURRAY, M.P.,
Mr. M'MORDIE, B.E.

F. A. FRANKLIN, Esq., C.E., in the Chair.

Mr. Harry A. Gilliat, Inspector of Public Tanks and Wells, called in and examined:—

3411. *Chairman.*] What is your official position? Inspector of Public Tanks and Wells. It is probable that under the new Watering-places Act of 1884, I shall be appointed with a fresh designation—it may be as Inspector of Public Watering-places. Mr. H. A. Gilliat. 12 Feb., 1885.

3412. Is that business to be under the supervision of the Mines Department? Yes.

3413. The information you have to give is from tabulated statements you have prepared? Yes; they were prepared from my own inspection, and were to accompany my annual report, which will to a certain extent review the work of five and a half years.

3414. Will you afford us some information as to the order in which you prepared your papers, with regard to tanks particularly? I have here (*Appendix* U 1) a list of the public watering-places at present in charge of the Mines Department, which consist of thirty-five tanks, seven wells, four dams, ten springs. There are twenty-five additional springs at the Peri tank, but except one, they are as yet undeveloped. There is also one large waterhole at Momba, on the line of road between Wilcannia and Hungerford, going up the Paroo. Tanks.

3415. Will you give us some information in the order of your summary, taking each item in its turn? I find by a rough memorandum here, which I made in anticipation of questions by the Commission, that of the tanks in charge of the Mines Department, we have twelve with a conserving capacity of 3,000,000 gallons each; sixteen with a capacity of 2,000,000 gallons each; one with a capacity of 4,000,000 gallons; one with a capacity of 12,000,000 gallons; giving a total of 73,500,000 gallons for thirty tanks, and an average of 2,450,000 for each tank. We are notified by the Department of Public Works of twenty-one new tanks now ready for transfer, and they will probably be transferred within the next few weeks. Of these, seventeen will have a conserving capacity of 3,000,000 gallons each, equalling 51,000,000 gallons; two will have a capacity of 5,000,000 each, equalling 10,000,000 gallons; two will have a capacity of 4,000,000 each, equalling 8,000,000 gallons; giving a total of 69,000,000 gallons, and an average per tank of 3,250,000 gallons. Capacity of tanks.

3416. Have these tanks been made under the superintendence of the Roads Branch of the Public Works Department? The Roads Branch construct the tanks.

3417. The return you have prepared is in reference to those tanks of which you are in possession or about to take possession? Yes; the last list has been handed to me by the Public Works Department as a list of the works they have completed, and which are now ready to be transferred to the Mines Department. Tanks in charge of the Mines Department.

3418. The proportion is about twenty-one tanks to thirty? There are thirty tanks in charge of the Mines Department, and there will be twenty-one more in the course of a few weeks.

3419. Do you know how long these twenty-one tanks have been in progress? No, but I do know that to a considerable extent the works have been delayed owing to the severity of the last three seasons.

3420. Can we get any record of the additional number of tanks constructed per year? Comparatively; my reports since 1869 will show the transfers to the Mines Department. Under the heading of the Stock Branch, I have given reports in 1881, 1882, and 1883, in the Annual Report to the Minister, of the tanks and wells. Tanks constructed per year.

3421. Could you give us a memorandum to be attached to the evidence, showing the tanks between the Darling and the Murrumbidgee in progress, and the increase each year in number? I first inspected tanks and wells in 1879. In 1880 I made my preliminary report, early in the year. I think we had then thirty watering-places completed and in progress; and since then in each successive year we have had a small increase in the number of works. But large numbers have been recommended for construction each year. The largest sum of money on the Estimates in any one year, prior to my appointment, for the construction of dams and wells, was £10,000. My recommendation was for thirty new works immediately, and we have been going on with twenty-five or thirty works per annum. But in the last three years it was almost impossible, in consequence of the drought, to get contractors to take up these works.

3422. Does any portion of the vote lapse if you do not make the expenditure? That rests with the Public Works Department. The whole of the construction is in the hands of Mr. Bennett, Commissioner and Engineer for Roads and Bridges.

3423. The vote has never been increased much from year to year? Large increases have been made since 1879. In 1880 or 1881 it was proposed to vest the subject in one Department, and a vote was obtained by the Mines for £50,000 sterling, but objection was made by the Department of Public Works to the surrender Vote of money.

Mr. H. A. Gilliat. 12 Feb., 1885.

surrender of the construction. It was subsequently arranged the Mines should take the control and maintenance of completed works, and that the construction and all repairs would remain with the Department of Public Works.

Advantage from Water Trust Department.

3424. Do you think that if a proper Water Trust Department were appointed you could expend a larger sum with greater advantage on this class of works? I think the whole question of water supply should be under one special branch to undertake the construction and maintenance.

Delay of works.

3425. You think that many projected works have not been carried out for want of a larger Department? I think they have possibly been delayed because we have not always had the necessary amount of money. With regard to this question there is an additional table to submit—watering-places recommended by the Mines Department and now in course of construction.

Works in progress.

3426. Will you give us, then, some information of the works at present in progress that you have in your Department, stating their situation? The watering-places now completed and in course of construction are enumerated in this list. (*Appendices* U 1, 2. 3, 4.)

Difficulties from drought.

3427. Any remarks you like to make with regard to these papers we can take, referring them to the particular letter? You asked the question whether any works had fallen through owing to the lapse of the money vote. I think when it has occurred it has been chiefly due to the difficulty of getting the work done in consequence of the drought. The exceptional severity of the season has made it difficult to get contractors to undertake and complete works in the interior. The Works Department has during 1884 transferred six new watering-places and refitted four old ones, and they now notify twenty-five new and four old watering-places as ready for immediate delivery to the Mines Branch. In addition to these, thirty-eight watering-places are in a more or less advanced stage of completion, and twenty-five others have been recommended for construction during the current year, making with the forty-six now in charge of the Mines Branch, a total of 134 public watering-places expected to be completed during 1885. This, averaging the distance between each at what is considered the standard distance, that is 15 miles, provides watering-places for 2,000 miles of road.

Tanks on stock routes.

3428. These tanks are on the established stock routes? Yes, with the exception of a few in villages. The schedules which I have put in give the district, the road, the locality of each tank, the approximate capacity (when we have been unable to take the measurement, which has been the case in some instances, as some of them have continued full of water), the depth of the water, and the length of the road upon which they are situated.

Works plotted on maps.

3429. Have you any plan in the Department on which these works are plotted? No. I made application for a clerk to do this, and one was appointed for my assistance; but the Chief Inspector of Stock required him so much for the clerical service that, although the map is ready, it has not been plotted.

3430. Is the information you give sufficient to enable us to plot on the general map the position of each watering-place? Perhaps not with accuracy. I think a more completely plotted map can be obtained from the Commissioner and Engineer for Roads and Bridges.

Sketch maps.

3431. *Mr. Donkin.*] You have no plans of the present tanks, but only of the proposed ones? We have had several sketch maps prepared to accompany my report of 1880, showing the approximate position on an ordinary Colony map.

3432. Not one up to date? No, and many blunders were made in it. We have nothing charted up to date.

3433. *Chairman.*] It would be an advantage to have these works plotted out, if it has not already been done? Yes, of course; and I think you could get ample information from Mr. Bennett which would supplement my answers.

Sites.

3434. *Mr. Donkin.*] Have the sites been fixed in reference to the boundaries of the runs approximately? The selection of site is made on a reserve, or immediately after the site is reserved and proclaimed the surveyor connects. More recently, within the last two years, we have made many efforts to get special leases laid out and fenced, and many of these are now laid out.

3435. *Chairman.*] Who, in the first instance, recommends the position of the tanks? It is my duty to make recommendations for water supply where I consider it is needed, to inspect the sites when water supply is applied for by different persons, and then to submit the recommendation to the Minister for Mines for his consideration. On his approval being given the recommendation is forwarded to the Public Works Department.

Instrumental examination.

3436. Then all instrumental examination is undertaken by the Works Department? Yes. As to the site, the arrangement between the Departments is that the Mines fixes the approximate site: but, and especially in the case of tanks, the Works Department finally establishes the site and settles whether the exact site selected, or some other, shall be adopted, where water may be conserved at a smaller expense.

Reports on effectiveness of tanks. Caretakers.

3437. I suppose you have regular reports from each of these places with regard to the effectiveness of each tank? The present arrangement probably will be altered when the regulations are completed under the Public Watering-places Act of 1884. Now we have caretakers where the tanks are not leased, and they make a weekly report to the Inspector of Stock in the district, who is acting overseer of tanks and wells, and to myself. The new instructions will be under the Public Watering-places Act, but they have not formally been issued, pending the Minister's approval. The overseer is directed to visit each works once in six weeks, but more frequently if his presence is necessary.

Caretakers' reports.

3438. Does he, in these visits, ascertain the depth of water and the consumption? The caretaker reports the depth of water at the end of each week. To ascertain the consumption would require a delicate system of gauges, and we should have to check off the loss from evaporation.

Evaporation.

3439. And you have no check system for evaporation I suppose? I submitted a paper to the Minister, eighteen months or two years ago, requesting that some action should be taken to test the evaporation, and I was put into communication with the Government Astronomer, whom I met two or three times on the subject. He did devise an instrument for the purpose, and he was to inform me further on the matter. As yet I have not obtained any of these instruments.

3440. Do you think you could trust an instrument of this kind to the ordinary class of officers engaged in these inspections, to enable them to check their reports? I should have to entrust them to the men upon whom I could rely. We could not check the evaporation in the main tanks. My idea was to have an iron tank filled with water and submerged in the main tank.

Observations at tanks.

3441. Do you think you have men competent for that work? I could pick out fairly good men in each district. I do not see the necessity for carrying out the observations at all tanks; it would be sufficient if they were made at one in each district.

Mr. H. A. Gilliat. 12 Feb., 1885.

3442. The delay in getting appliances has prevented you from getting this information? Mr. Russell, the Government Astronomer, was to inform me when they were completed.

3443. In their reports to you, do the men in charge refer to the construction of tanks, or make reference to what they may consider a better construction? That comes within Mr. Bennett's province. The new works I think have fulfilled very fairly the requisite conditions. In what is now called the standard tank the objections at first made have been got rid of. Standard tank.

3444. That is a rectangular tank with an embankment round it, and you throw the water from the inside into a trough outside? The water is served to stock from the new standard tank by lifting it with a Tangye pump, geared direct to horse power, by delivery pipes passing through the embankment into a service tank having a capacity of from 15,000 to 20,000 gallons. The water is then run out by a tap into a trough. Watering of stock.

3445. You think this is about the most effective system? Yes. If we had a larger rainfall, undoubtedly the better plan would be to make large excavations, let them fill, and allow the stock to be watered from them direct; but as the rainfall for several years has not given sufficient water from the catchment area to run into the tank I think it necessary to be careful of the water, and therefore advocate the service of water by troughing.

3446. *Mr. Donkin.*] Are orders given to keep the service tanks filled? Orders are given to keep the service tanks full always; it keeps them in better order, and there is a quantity equal to from 15,000 to 20,000 gallons of water ready to meet any emergency. Service tanks.

3447. Is there a man in charge of each tank? Yes. Where a tank is leased the tenant keeps a man in charge; where a tank is under Government charge, there is a caretaker. Tanks leased.

3448. *Chairman.*] In some tanks there is an approach with a slope of 4 to 1? There were three between Nyngan and Cobar, with direct approaches; they are now being fitted with pumps and troughing. The early tanks were with slopes of 1 to 1; now we have them with slopes of 1½ to 1. Approaches.

3449. Did you ever observe that, in watering stock in a sloping approach, a great deal of water was lost by being carried away in the fleeces? In my reports to the Department I have continually pointed out the loss of water from this cause, and stated that while a thirsty sheep may drink a gallon when admitted to the tank, it is impossible to say how much they carry out in their fleeces. I have seen several hundred swimming in a dam at one time. Loss of water.

3450. You have never tried to gauge the amount of soak-up by a sheep's fleece? No.

3451. You have come to the conclusion that it is a bad system of watering? Decidedly. I am in favour of watering by troughing, and that plan is adopted in all new works. The only question now is as to the adoption of steam pumps where there is fuel at hand. Watering by troughing

3452. *Mr. Donkin.*] In place of horse-power? Yes. In some of the new works the pumps are being driven by steam. Pumps.

3453. *Chairman.*] In face of the great difficulty with regard to labour in the interior, would it not be an advantage to get large excavations without so much finish to the slopes and angles? I think little advantage is to be gained by extreme finish if we get a containing capacity. I should prefer to see the money which is expended on great finish spent in increasing the depth, and so reducing the evaporation. Finish of slopes and angles.

3454. *Mr. M'Mordie.*] Do you think that finishing off the work is an expensive process? The embankments have to be trimmed and the slopes to be adapted to the exact batter. Expense.

3455. Is that an expensive process? Yes; it has to be done by hand-work.

3456. *Chairman.*] The other form could be given by the steam appliances in use? There I agree with Mr. Bennett, so far as steam-power has yet been used. We get very low slopes, and there is consequently an increased tendency for the water to splash up round the edges of the bank, and this especially in hot and windy weather.

3457. *Mr. Donkin.*] What are the slopes made by steam appliances? I think the Fowler slopes are 4 to 1. In a letter Mr. Doudney asked me whether I would consent to this if the Works Department did, in the event of his increasing the depth. I do not know what contract he entered into with the Works Department, but his view was to preserve slopes of 1½ to 1 side batter, and to increase them at the end. I replied that I saw no objection to that, provided he increased the depth, and these concessions being granted he would reduce the price; but as Mr. Doudney asked as much as other contractors, I did not see that much was gained, because we got a better finished work from the others. Work by steam appliances.

3458. Do any private individuals make the slope, 1½ to 1? Within the last two years I have had so much fieldwork that I have had little opportunity of inspecting private tanks. As it was impossible to carry forage, I have rarely been able to quit the main roads. Private tanks.

3459. Mr. Doudney says that Mr. Edols makes his tanks with slopes of 3 to 1? I think Mr. Edols was previously owner of Mr. Doudney's plant. I have gone carefully into the matter, and think that if you scale a slope of 1½ to 1, and another of 3 to 1, you will find there is an enormous difference. I find that our new tanks have stood very well with slopes of 1½ to 1. Slopes.

3460. Can you give in the standard specification of these tanks: I think you say one has been adopted? That must be obtained from the Works Department; it will then be exact. Standard specification.

3461. You recommend supply tanks, but you do not say anything about silt tanks—do you recommend that the water be directed at once into the main tanks? No. In all cases the water passes from silt tanks. I am in favour of a larger system of silt pits or tanks. The flood-water now drains into the silt-tank. In order to save expense there is but one silt usually, but unless rain falls rapidly in large volume it does not drain directly into the tanks. Silt tanks.

3462. What is the height of the embankment? It settles to about 12 feet. Embankments.

3463. Do you recommend generally embankments around tanks? I do. Seeing the necessity for an increased water supply, I recommended, in my report of 1880 or 1881, that we should have a portable engine on the roads to fill the embankments, or make arrangements with neighbouring squatters to keep them full in cases of heavy floods. There is 2, 3, or 4 feet of water now lying outside some of these tanks.

3464. In level country is any object served by these embankments? Yes, protection from wind.

3465. In reference to the tank 5 miles from Melrose, between Condobolin and Nymagee, Mr. Doudney said—"All round the tank I suppose the embankment is 15 feet high, and the water passes into the tank from the flume into the silt tank"; and when I asked if the tank was full, he said "No"? This tank has not been transferred to the Mines Department, and I have not seen it.

3466. *Chairman.*] I suppose there is a record of the cases of repairs to each tank, including cost in wages and supervision? That can be obtained from the Chief Inspector of Stock. Repairs.

Mr. H. A. Gilliat. 12 Feb., 1885.

3467. Would it be possible to put in evidence the expense for one year? That can be done by the Chief Inspector of Stock. I find the only tank that I know on the line Condobolin to Cobar that Mr. Doudney put down—namely, the Tinda—was reported before the late rains to be two-thirds full. The return is from the Works Department, in reply to a minute from the Secretary for Mines.

Spoil. 3468. *Mr. Donkin.*] Do you consider that the spoil used in forming the embankment should be made to conform to a certain batter, and do you approve of embankments on level country? On perfectly level country there are no means of taking up the surplus water; but the spoil has to be removed, and in many cases I think it would be better removed into a horseshoe-shaped dam, to increase the water-level over the excavation. When the levels are taken, there may be found to be a slight depression to be taken advantage of. In any place where the catchment area is large, and the natural features such as to collect a quantity of flood-water rapidly in the neighbourhood, I believe in the high embankment, for the purpose of pumping in.

Slight depressions.

Slopes. 3469. There must be a slope towards all tanks? Of course.

3470. And it is usual to have the embankment round in the semicircular way you describe? Yes.

Batter of spoil. 3471. I understand you to say that, in putting spoil round the tank, in order to pump the outside water, it is not necessary that the spoil should have an exact batter? I think not, if sufficient dressing is done for neatness. Where the spoil has been spilt by the cart or motor, a great deal tumbles on the space between the excavation and the foot of the embankment. All that should be dressed off and carted away.

Effect of embankment. 3472. *Chairman.*] Do you not think that the raised embankments round rectangular tanks prevent the operation of the sun's rays upon the water to some extent? I think it saves the water from the effect of hot winds. I have seen the water in station tanks evaporate rapidly during a strong wind,—much more than it would do on the hottest still day. By the wind the water is dashed against the soil at the sides of the tank and absorbed and quickly evaporated, which must be added to that taken up by the rapid passage of the hot dry air. The embankment is a decided protection against the prevailing winds, which during the summer are generally from the south-west.

Height of embankment. 3473. Would it be an advantage to have an increased height for the embankment? I am not prepared to recommend an increased height; it would be a great increase in expense.

Trees. 3474. Have you made any attempt at growing trees or shrubs on the spoil banks? We had a suggestion from one officer to raise some grass on the embankments, and I have recommended to the caretaker to place some polygonum or cane-grass on the banks, but in the last three years this could not be done.

Aquatic plants. 3475. *Mr. Donkin.*] Has there been any attempt to grow the large Indian water-lilies? There has been no attempt to grow aquatic plants on the banks.

3476. In India they find these lilies serviceable in counteracting evaporation? I am aware of that, but it is questionable whether we should be able to grow them in the tanks, many of which are impregnated with gypsum. But I should add that at several tanks, where the water is impregnated with gypsum to such an extent as to be unfit for human consumption, a large amount of aquatic weeds have made their appearance, but they do not cover the surface like the broad-leaved lily.

3477. Would you recommend the planting of these lilies? If the experiment succeeded it would be valuable; but there is a great depth in the body of the tanks. I think they may be tried along the batters which are protected from stock. Some of the tanks in India are about the same depth as those here, and there the large-leaved lilies grow magnificently.

Erosion of banks. 3478. *Chairman.*] In India I think they adopt a system to prevent the erosion of the banks by the action of steamers, by growing a dwarf rush: I suppose the level in your tanks is not sufficiently constant for that? The level varies through evaporation and through consumption by stock. We may have 18 feet of water in a tank, and in a few months afterwards only 10 feet.

Silt. 3479. Does the cutting away of the bank materially silt the tank? Very much indeed.

Floating guard. 3480. Did it ever occur to you that a floating guard on the water would preserve the banks? I hardly think it would be practicable.

Protection of banks. 3481. You think that nothing in a simple way could be done to prevent the erosion of the banks? If it is found the present batter is too steep it must be slightly reduced, but I think that with the present form of tanks and embankments we protect the water from the action of wind to a large extent; and the stock being supplied from troughing, the wash of the banks will be reduced to a minimum. The bank will always wear away a little at the surface. Later I shall be able to give more information, as I find from experience how the excavations of the new tanks stand.

Planting of trees. 3482. Under the present supervision, would it be possible to have a few trees planted by the care takers on the banks, in order to test that plan? Yes. But the labour question is a difficult one. Hitherto the men have camped out at these tanks, but now it is proposed to erect huts for caretakers, and that will probably induce a better class of tenants or caretakers to undertake the work—men with wives and families. We have some men who, under the direction of the overseer, would give careful attention to any plants sent, and see that they were watered and cared for. I have seen some very permanent tanks in the dry parts of India perfectly protected by old trees on the top of the embankment. Our eucalypti would probably grow freely, but they absorb an immense quantity of water by the roots, so that the cure by this means would be worse than the disease.

Suitable trees. 3483. Could you ascertain what suitable trees are peculiar to the locality, for the purpose of testing this plan of protection? I could make the experiment at several of the works; for instance, there are three large tanks between Hay and Deniliquin, none of them having bitter water, so that the experiment suggested might be favourably made there.

Watering of trees. 3484. Would the men, do you think, undertake the extra duty of watering the trees whilst they were young? I think that at each of these works there are men who would take an interest in the matter, and see that the caretakers paid proper attention to the trees. I should be glad to carry out the wishes of the Commission at any time they choose to communicate with me, and I would give instructions, subject to the approval of the Minister, for the suggested improvements being effected.

Position of trees. 3485. *Mr. M'Mordie.*] It would not do to plant trees on banks intended to hold water? No, nor within the embankments—the earth there would be too soft; they must be outside, or in the neighbourhood of the silt tank.

3486. *Chairman.*] And they must be in the direction of the prevailing winds? Yes. Lilies and plants of that nature could be planted along the side of the excavation when the water was low.

Mr. H. A. Gilliat. 12 Feb., 1885.

3487. *Mr. Donkin.*] In speaking of the spoil being used for embankments to prevent the effect of winds upon the water, do you think that stakes and wicker-work would do as well? Of course you refer to tanks on great plains, and then the question arises as to where you are to get the wicker-work and timber. I have known cases in which slip panels had to be brought 30 or 40, or even 50 miles.

Stakes. Wicker-work.

3488. In the evidence with regard to the Tinda tanks, it appears that the contractor suggested the use of stakes and wicker-work? That was in a timbered country. There is a good fence suited to enclose tanks and embankments: a trench is dug, 2 feet 6 inches deep, stakes are put in it upright, and are well rammed in. When you could get the timber this does very well, and affords an admirable protection.

Drop fence.

3489. For enclosing, the drop fence is the best? A good deal depends on the saplings. A number of them are put in with a wire winding in and out to bind them.

3490. Did you state the number of tanks now in working order and in use? I gave the number of the works in charge of the Mines Department.

3491. Are those you mentioned in use and available? Yes.

Repairs and alterations. Pump.

3492. Many people from the back country report them as useless and not in working order? You refer probably to the Wilcannia Road. I recommended repairs and alterations at the whole of the watering-places of the Colony, consisting of troughing, service tanks, and pumping gear. A few of the tanks were fitted with M'Comas' water-lift. These were found in practice to get out of order. My view was to get the simplest gear, which was the double web, but that was disapproved of and the present Tangye pump was substituted.

3493. *Chairman.*] Is that pump effective? Yes, it is an excellent pump. With occasional repacking it will stand very well, and is sufficiently strong to bear the rough treatment of the men we employ.

Tanks in order.

3494. *Mr. Donkin.*] Then all the tanks are in working order? It was reported a few days ago that the Till Till tank was out of order. The alterations and repairs have not been completed, but stock and carriers can get water. The Boonoona is an old tank which was silted up very much, and the embankments have been trodden down, and the old water-lift had disappeared when I first saw it 1879. Stock are now admitted to the excavation until it is reconstructed. The 35-mile tank is dry.

Life of tank.

3495. *Chairman.*] The Boonoona tank is about fourteen years old—is that about the life of our tanks? I think the Boonoona tank, if repaired, would be as good now as it was originally, but the life of a tank depends upon the silt it collects.

Tanks out of order.

3496. *Mr. Donkin.*] Then there is some truth that some of the tanks are not in working order? If you mean that there are many places where stock cannot obtain water from them, I may say I do not think there is one, except when the supply has failed owing to the drought. Provision can be made to supply water at any of these tanks. For the last few years but little stock, comparatively, has been travelling.

Watering-places Act of 1884.

3497. *Chairman.*] Under the Lands Act of 1884 better provision, you think, is made for the administration of the watering-places? No, under the Watering-places Act of 1884. There were no means, prior to the passing of that Act, of protecting the works from trespass, damage, or pollution; we could not recover damages or punish the offender by prosecution; there was no statute under which a charge could be brought.

Wells.

3498. *Mr. Donkin.*] Have you anything to do with wells? Yes—with the inspection of them.

3499. But not the recommendation of the sites? Yes.

Drills Branch.

3500. Do you work in conjunction with Mr. Henderson? I have nothing to do with him. The Drills Branch have bored on lines of road where I recommended the use of the drill. After consulting with Mr. Wilkinson, the Government Geologist, I recommended boring on the line from Bourke, *via* Wanaaring, to Tibbaburra, which is near Mount Browne.

3501. The present road to Tibbaburra is *via* Wilcannia? Yes.

3502. Then at present there are three Departments dealing with water conservation—the Drill Department, yourself, and Mr. Bennett? There are three different branches in this Department.

Sites for tests.

3503. *Chairman.*] You indicate the site for tests, and Mr. Henderson carries out the practical work? I have only to indicate a line of road where I think boring can be practically carried out. The first line I indicated was that from Bourke to Tibbaburra, *via* Wanaaring; the second was from Collarindabri on the Barwon, by the 60-mile track, to Angledool on the Narran; the third was from Wilcannia to Thackeringa, near Silverton. Mr. Wilkinson, the Government Geologist, thought there was a fine promise of obtaining water on these lines.

3504. Can you say approximately when you recommended the road from Bourke to Tibbaburra? I think about three years ago.

3505. Did you recommend the route from Bourke to Goonery, on the Warrego? No; I was not consulted in the matter. The only recommendation which I made was that in all cases it would be desirable for the officer in charge of the boring party, if he had more than one plant, to commence boring as nearly as possible in the centre of his route. What was the object of boring at Gooney I did not see, because there was in that locality a spring on a Government reserve. I recommended that the borings should be 15 miles apart, which is adopted as the standard distance.

3506. You know that part of the route is closed? Yes, from Bourke to Tibbaburra.

Schedule of wells.

3507. *Chairman.*] One of the Schedules you produce gives all the particulars of wells? Yes; I think the bulk of the particulars you require.

Supply and quality of water.

3508. Can you inform us whether in all cases the water is permanent? There are many points to be taken into consideration with regard to wells. For instance, a well in one line of country where water is invariably found will be brackish. In those cases we generally found an inexhaustible supply; but where at the same depth the water is sweeter and otherwise better the supply often is smaller.

3509. Will you prepare for future examination all the information you can get on wells? Yes; I shall be very glad to do so.

Information on wells.

3510. If you could tabulate it and bring it under several heads—sinkings where good water is obtained, cases where it is or is not permanent—the information would come in a very useful form? Yes. I understand that Mr. Henderson is preparing a map on which all the known wells are laid down. I can give information about the lines of route, where brackish water is usually found, and where experimental shafts have been sunk.

3511. *Mr. Gipps.*] Did you reach the silurian rocks in boring? I had nothing to do with the boring, and do not know the character of the strata penetrated. On the Bourke line it is reported that in October last a depth of 448 feet was reached, and that they were in the cretaceous. I see that lately they have gone down 478 feet and are still going on sinking.

Mr. H. A. Gilliat. 12 Feb., 1885.

3512. *Mr. Donkin.*] After you have recommended a route to be opened you have nothing more to do with the work? Not until the completion of the work is notified; then I have to inspect and report upon it, for the satisfaction of my own Department.

3513. I think I understood you to say that these works are at present under three branches, and that under the new Act they will merge into one? No; the Public Watering-places Act of 1884 is for the administration and protection of these works, and also for legalizing the construction and maintenance.

THURSDAY, 26 FEBRUARY, 1885.

Present:—

MR. BARTON, M.P., | MR. FRANKLIN, C.E.,
MR. DONKIN, J.P., | MR. GIPPS, C.E.,
MR. M'MORDIE, B.E., C.E.

RUSSELL BARTON, ESQ., M.P., IN THE CHAIR.

Mr. Charles G. W. Lockhart called in and examined:—

Mr. C. G. W. Lockhart. 26 Feb., 1885.

3514. *Chairman.*] I think you were examined before the Select Committee of the Legislative Council on Mr. Brodribb's Pastoral Dams Bill. We wish to obtain any reliable information as to the water-courses which may be available for irrigation in the particular districts of the country in which you have had the greatest experience? I shall begin by making the rather startling assertion—and I dare say but a few will believe me—that there is a great deal more water than there need be.

Abundance of water.

3515. In the rivers? No; in the back blocks. The fact of the matter is that the squatters have had their runs overstocked. They have had too much water. They have lost sheep where there has been abundance of water.

Want of grass.

3516. *Mr. Donkin.*] The water would not kill them? No; they are killed through the want of grass. They seemed to think that if they once sank wells and obtained water they would be safe.

3517. Do you think that all runs are in that position? Most of the runs on the Darling.

Water conservation.

3518. Are you of opinion, then, that there is no need for a scheme of water conservation in that country? I say that in the case of many of the runs the lessees have done so much in that direction that there is no need for more to be done, if their works be legally protected.

3519. Do you not think that millions of gallons of water run to waste down the Darling, Murrumbidgee, Lachlan, and Murray? Even if that were not the case, you would be unable to keep any more sheep.

Irrigation.

No one is better acquainted than I am with the utility of irrigation. I have pumped water on to one or two acres of land, and have obtained the most astonishing results. I have irrigated a garden. I had in the first place to dig out the salt-bush soil to a depth of 2 feet; I then had soil brought in from the sand-hills. By irrigating that land I obtained wonderful results.

3520. But you think that if we kept all these rivers full not a sheep more could be kept? Yes.

3521. In good seasons there is plenty of natural food for sheep on these plains? Yes.

Sufficiency of present supply.

3522. *Mr. Franklin.*] You think that the present water supply is sufficient for stock: if there were a more abundant supply, would there not be room for a closer settlement for agricultural purposes? No.

3523. On the land between the Darling and the Lachlan would it not be of special advantage to make a more permanent supply of water by conserving the river waste? The squatters have done so much that I do not think there is any need to do more in that direction for their benefit.

3524. *Chairman.*] Do you know of any run on this side of the Darling on which sheep were lost for want of water this year? No. If that portion of the country will grow nothing but sheep, then I think you ought not to carry out any expensive scheme of conservation at the expense of the public. If you give the lessees a secure holding they will do all that is necessary themselves. If they do not do so, let them suffer the consequences.

Irrigation.

3525. *Mr. Gipps.*] Have you had any practical experience in irrigation? I have seen plenty of irrigation works in Scotland, and in this country I have had a pump on my own land.

3526. What was the nature of the soil you irrigated? Black soil.

3527. What was the character of the crops? Oranges, figs, and grapes, and all tropical fruits. Judge Forbes said that he had never seen such crops of oranges at Parramatta.

3528. What number of waterings were there? I watered my trees once every three weeks.

3529. What quantity of water did you use? I could not say.

3530. You found that you had always sufficient water in the driest seasons? Yes, I always had sufficient.

3531. What was the horse power of the windmill? About 4-horse power.

3532. How many hours consecutively did you pump? I used to fill reservoirs of 400-gallon tanks. Mr. Holding has a fine orangery at the junction of the Darling and Murrumbidgee.

Usefulness of water conservation.

3533. *Chairman.*] Then it is your opinion that it would not be advisable to go to any expense in conserving water, either for the purpose of irrigation or for stock purposes, between the Darling and the Lachlan, or between the Lachlan and the Murrumbidgee? Certainly not for stock purposes. The people are very well able to do it for themselves if their works be protected. I do not know about the growth of wheat, but we can get other crops to grow in a wonderful way.

Lucerne growing.

3534. Do you not think it would be worth one's while to grow lucerne? A friend of mine, Mr. Cresier, grows lucerne. He has a Tangye steam pump, and he saves himself an immense sum of money in his horse-feed.

Droughts and floods.

3535. Have you had much experience of the country between the Darling and the Lachlan? I have lived there on and off for the past forty-five years. I have seen three or four great floods and an equal number of great droughts.

Change of condition of country.

3536. *Mr. Franklin.*] Do you not think it would be possible to change the condition of some portion of this country by a constant supply of water, so as to make it available for agricultural enterprise? I do not think so. No one is more anxious than I am to see the country progress; but I do not believe that could be done. All that a man wants is a little lucerne for his horses and cows. How could you encourage a man to go out into this part of the country with a view to grow wheat?

3537. Could not some of the water be utilized for the growth of artificial feed? There would not be sufficient to grow artificial feed for all the sheep. Besides, if you give the sheep fair play they are always fat and well, and they are absolutely free from disease. Mr. C. G. W. Lockhart. 26 Feb., 1885.

3538. How many acres would you allow to the sheep? I would not keep more than a sheep to 5 acres.

3539. *Chairman.*] Then you do not think that any great benefit would be derived from the conservation by the State of a large body of water in this district? I would not spend any Government money there except upon watering stock routes or townships. Conservation of water for stock routes.

3540. *Mr. Franklin.*] What we wanted to find out was, whether it would be possible to conserve a certain quantity of water now running to waste, not for the feeding of sheep but for the growth of agricultural crops? I believe there is enough water running to waste to enable you to do so, if you could stop it. Conservation for agricultural crops.

3541. Do you think it would be a commercial success? That I cannot say.

3542. Would there not be a market among the run-holders—would they not buy hay to feed their sheep? No.

3543. Not at a cheap rate? I cannot imagine hay being grown at a rate sufficiently cheap.

3544. You know that in India vast herds are fed by artificial grasses? Where are you going to find in this Colony the men who will work like the patient Hindoos?

THURSDAY, 5 MARCH, 1885.

Present:—

MR. BARTON, M.P., | MR. GIPPS, C.E.,
MR. FRANKLIN, C.E., | MR. M'MORDIE, B.E.

RUSSELL BARTON, ESQ., M.P., IN THE CHAIR.

Mr. Harry A. Gilliat, Inspector of Public Tanks and Wells, further examined:— Mr. H. A. Gilliat. 5 Mar., 1885.

3545. *Chairman.*] You produce a number of papers? Yes; Annual Reports of my Department, and my evidence before the Select Committee of the Legislative Council on the Pastoral Dams Bill.

3546. What is the nature of the bank and bed of the river Lachlan near the head of the Willandra Billabong? I have never measured the banks of the river at the place indicated, but it is a narrow stream with precipitous banks with stiff upper clay. I have never examined them lower down to ascertain their strata. Banks of Lachlan.

3547. What do you understand the "summer level" to mean? I take it that it means the level at which the water stands on an average during a number of seasons. In the summer months the river Lachlan almost ceases to run, and the summer level is the height of the water in the large waterholes which remain. The summer level, as given at some of the large townships—Wilcannia for example—is absolutely unreliable. Summer level.

3548. Do you think that it would be practicable to construct a weir across the Lachlan, so as to send a large supply of water down the Willandra Billabong? I have not the least doubt of it. Taking the whole length of the Lachlan, with the exception of the Reed Beds below Oxley, I hardly know of any place where within a few miles you would not be able to place a weir. Weirs across the Lachlan.

3549. What would be the probable height and length of a weir across the river near the Willandra? I think that a suitable site might be selected there, but I cannot give the height to which it would be necessary to raise the weir to force the water into the Willandra, as I have not taken levels. About a year ago a paper written by the Chief Inspector of Stock was sent to me. That officer had an idea that by constructing a weir across the Lachlan, the Willandra might be flushed and the rabbits there be drowned. I thought it impossible under the present state of the law to so deal with the water of the Lachlan, but suggested that an excellent and practical officer living at Hay—Mr. John Keighran—should be asked to report on the subject. He reported that it would be practicable to put a weir across the river, but he did not think that the owners on the river below would allow the weir to stand. I think that a spot might be found where the width of a weir would not exceed 150 feet. The height I am not prepared to state, but it would not be very great I think. Dimensions of weir.

3550. Then no stupendous works would be necessary? Not at all.

3551. What dams have been made across the Willandra Billabong, and what are their approximate positions? To the best of my recollection there are five dams on Messrs. Whittingham's Willandra run up to the boundary of Mossgiel. There are two dams I think on Mossgiel run, one on Bundarra run, and three on Kilfera. I am not certain as to the number (if any) of dams on Clare run. The Willandra fills one or two lakes below that—Barney's Lake, and I think a small dam is on the lower side of it. Dams on the Willandra.

3552. Then there are twelve dams on the course of the Billabong? Yes, to the best of my recollection; I am not at all positive.

3553. *Mr. Franklin.*] What is the total distance over which the dams extend? I can speak approximately only. In wet seasons the billabong extends within from 15 to 20 miles of Lake Teryaweynya. Distance.

3554. *Chairman.*] You are quite clear as to the course of the Willandra Billabong? Yes. You cross it at Mossgiel-station, 3 miles beyond the township. It is well defined there. There is no well defined water-course after leaving the Merowie Creek until you reach the Talyawalka, near Wilcannia. The billabong is tortuous in its course; it has a northerly trend after passing Mossgiel. Course of Willandra.

3555. What is the general character of the country through which it passes? The lower part consists of fine salt-bush plains, in good seasons with plenty of grass and herbage. This class of country extends past Mossgiel; all open country, with little or no scrub. Character of country.

3556. For what distance? That I can hardly say. Following its course I should judge it runs through 80 or 100 miles of this country. After leaving Clare and passing into Kilfera the country becomes heavily scrubbed in places, and as the Teryawynya is approached the scrub gets denser, with occasional plains.

3557. Does the creek become shallower and its banks flatter as the distance from the Lachlan increases? It is a well defined creek to Mossgiel, and also on some parts of the Kilfera run, but after that it rapidly loses its formation. In some places it widens out in claypan swamps, and then reforms again. Bed of creek.

Mr. H. A. Gilliat. 5 Mar., 1885. Mossgiel. Banks. Dimensions of the Willandra.

3558. Is Mossgiel on the Willandra Billabong? Mossgiel station is quite close to the creek, and the township is about 3 miles south of it.

3559. For about what distance from the Lachlan are the banks of the creek well defined? Following its course, it is distinguishable as a large creek for certainly 80 miles.

3560. Can you give any idea as to the dimensions of the Willandra at intervals of 20 or 30 miles from its head—that is, where it takes off from the Lachlan? That can only be arrived at by taking a series of measurements. Where I have crossed the creek it is shallow and wide, the road being chosen to cross it in places where the banks are not steep.

3561. You have never examined the creek with a view to determine whether dams might be made across it? No, except in the neighbourhood of Mossgiel, where I once submitted, as an alternative for a tank, a dam across the Willandra.

Course of creek. 3562. Is the course of the creek very tortuous? Very much so indeed.*

Obstructions. 3563. Are there many obstructions in the shape of timber or silt-banks? Not many. There are old channels and by-washes, such as are usually formed on these flat plains where there is so slight a fall. There are also small islands formed by ana-branches running to and from the creek.

Distance reached by floods. 3564. Do you know what is the furthest point to which water has flowed in the Willandra from the Lachlan at flood-time? I have seen water from the Willandra fill a small lake at Kilfera head station.

3565. What distance, approximately, would that be from the Lachlan? Following the sinuous course of the creek, about 200 miles, I should judge. The distance from Kilfera to Teryawynya Lake is about 72 miles in a direct line.

3566. What is the average width and depth of the Willandra at its head? I cannot say, as I have not made any measurements.

Water running back. 3567. When a flood occurs in the Lachlan, and the water runs along the Willandra, does the water flow back into the Lachlan in the event of the flood subsiding rapidly? I can give no information about that. I have heard it said that there is a back flow. I have never been at the entrance of the Willandra at a flood-time.

Natural depressions. 3568. Do you know whether along the course of the creek there are any natural depressions in which large quantities of water might be stored? There are a number of lakes, some of which have been reserved, I believe; they are either portions of the creek where it spreads out or are near to it. There is Barney's Lake, on Clare Station, and further on there is Willpania Lake. There are several boxes or clumps of timber surrounding lagoons along the course of the Willandra, and these boxes are filled by overflows from the creek. There is a box about 9 miles from Mossgiel, where, in 1882, I noticed that a number of Chinamen had established a large potato garden.

Water storage. 3569. If water storage on an extensive scale can be carried out on the Willandra, do you think that the owners or occupiers of land adjacent could make use of the water for irrigation? That opens up a large question. I doubt whether a sufficient quantity of water could be got from the Willandra for irrigation purposes, except on a very small scale. A quantity of water might be stored by diverting into tanks for the use of stock.

Storage of Darling flood-waters. 3570. Do you think that it is practicable to store large quantities of the flood-waters of the Darling in the lakes and large natural depressions near its course? I think so. There are many places where the flood-waters of the Darling which now run to waste in all directions might easily be stored, particularly in the series of larger lakes on the lower part of the river.

3571. Will you describe and point out on the map the lakes which you think might most easily be utilized for such storage? I am simply offering a general opinion; I should not like to name any particular places, as careful surveys will have to be made before forming a definite opinion.

3572. But, from your knowledge of the river and the lakes, you think that there are a number of lakes where water might be stored? Yes. I can speak more confidently of the lakes on the Paroo, which I have marked on the map, and of which I have made a rough horseback survey.

Banks of lakes. 3573. Are there any of the lakes with banks of sufficient height to hold water up to the highest flood-level of the Darling, or nearly so? I do not think so. I think that they will all require more or less artificial embankments to make them retain water to such a level.

3574. Have you in any case ascertained whether, by the construction of dams provided with sluice-gates, the water can be permanently stored in these lakes? I cannot answer this question, as I have not taken any measurements. The only locality to which I have paid particular attention has been on the Lachlan, with a view to fill Lake Cudgellico with water.

Country between Lachlan and Darling. 3575. What is the general nature of the country between the Lachlan and the Darling? Taking Hillston as the initial point, and thence to Cobar, and thence to Louth or Bourke, leaving Hillston, the country rises until the hills are reached, and from there it gradually descends with a general westerly slope. This continues to a point beyond Cobar, the country being sandy and scrubby, and in places heavily timbered. From a point near Louth, about 20 or 30 miles back from the Darling, commences the ascent of Rankin's Hill Range, which follows generally a south-easterly course for a few miles, then trends south, and then westerly again, giving a gradual fall westward. There is a belt of mallee, which continues north and north-west from 30 miles north of Hillston until it crosses the road between Wilcannia and Booligal, about 30 miles from the former township. This area is interspersed with really magnificent salt-bush and grass country in the eastern portion. Falling to the westward until you get on to the great salt-bush plains, much of the country nearest to the Darling, and some miles back from it, is covered with heavy scrub. Most of it is edible, sufficiently good to keep sheep alive and to fatten cattle. In 1884, I saw cattle fed on this scrub which were as fat as if they had been in first-class paddocks. The general character of the flat salt-bush plains continues away westward until you reach the plains beyond Kilfera and Clare. Then the character of the country gradually changes and gets worse and worse. Taking the corner contained within a line from Menindie down to Euston, down the Murray to Wentworth, and thence to Menindie, the land is about the worst in this part of the Colony—poor, inferior land, covered with mallee and sand. This poor country forms a triangle, of which the Darling and the Murray are two sides, and a line between Menindie and Euston the hypothenuse. As a rule, the Darling River frontages are of indifferent quality; but going back from the river the country improves and gets richer.

3576. *Mr. Gipps.*] What is the character of the soil in the triangular area to which you have referred? Sandhills intermixed with stiff white clays.

3577. Is it subject to floods? In some places. 3578.

* Note (*on revision*):—*Vide*, for a portion of creek, run map, county Mossgiel.

Mr. H. A. Gilliat. 5 Mar., 1885.

3578. *Chairman.*] Do you think that there is any chance of its being found practicable to convey flood-waters towards Cobar from the Lachlan or the upper part of the Bogan? It may be possible from the upper part of the Bogan. The levels which I have taken have been merely with aneroids, and are subject to correction; but four or five observations which I made showed that Cobar is from 435 to 450 feet above the level of the river Darling at Bourke. Your engineer tells me that levels which he has taken accord with mine to within 10 or 15 feet. Conveyance of water towards Cobar.

3579. Then you think that there is more chance of bringing water into the Cobar district from the Upper Bogan than from the Upper Lachlan? I think the Upper Bogan has the higher elevation of the two. I do not think that you could get water from the Lachlan to Cobar.

3580. Do you know of any channel besides the Willandra in which flood water can be conveyed far into the interior part of the country on the Darling and Lachlan? No doubt by the erection of weirs the Merowie or Box Creeks could be filled with water in the same way as the Willandra. Back from the Lachlan, on the Walgeirs run, there is a fine group of lakes, which might be filled, perhaps, by water brought from the Lachlan through the Merowie, but many of these, I think, have been alienated. Merowie and Box Creeks.

3581. Do you know of any sites suitable for reservoirs on a large scale between the Lachlan and the Darling? I cannot reply to that question, as I have not made any surveys. Reservoirs.

3582. Do you think that such sites may be found? I have not the least doubt of it. There is a gradual rise in the country about 30 miles after you leave Mossgiel. I left that place the day after a 3-inch fall of rain, drove 35 miles by a back track running parallel with the main road. For a number of miles the water was flowing slowly towards the west, and was above my horse's fetlocks until I began to rise on the opposite slope. This circumstance leads me to the conclusion that in that part of the country you will find places where large quantities of water may be stored. Then, about 30 miles from the Willandra Billabong, following the road northerly, there is a curious series of low red clay and sandy hills, from which I think there must be a large amount of drainage on to the lower country. Then following that line to the east and then to the north-east and north, there are numbers of clay-pan swamps, indicating depressions. Country about Mossgiel.

3583. What is your opinion of Lake Cudgellico as a storage reservoir for flood-waters? It is invaluable. I think that an inexpensive weir in the Lachlan and a trap in the creek would retain water permanently in the lake. Lake Cudgellico.

3584. *Mr. Franklin.*] Is there any outlet from the lake? I am not aware of any, except the creek which is both the affluent and the effluent.

3585. *Chairman.*] Have any efforts been made to retain water in the lake? I have heard that a trap was put in the creek, but it was washed away.

3586. Do you think that the storage capacity of the lake would be materially increased by a trap being placed in the creek? Undoubtedly. Storage capacity.

3587. What is the quality of the land near the lake? It is fair pastoral country; it is principally open box country, and much of the land would be very good for agricultural purposes, if there were plenty of water available. Quality of land.

3588. If there were plenty of water, do you think that irrigation would be resorted to? That I cannot say. If the water were there, and it would not be too expensive to get it on to the ground, no doubt people would avail themselves of it. Irrigation.

3589. Do you know anything about the opinions of the land-owners on the subject of the improvement of the lake? No; I have not had an opportunity to speak to them respecting it.

3590. *Mr. Franklin.*] Is the whole of the lake included in one run? I think not; but I am not sure. There has been a good deal of selection and mining about there. In fairly good seasons there must be a considerable fall of water from the Corapara Ranges towards the lake; I fancy there must be small creeks running into it. Water from Corapara Ranges.

3591. *Chairman.*] In the country west and north of the Darling will you describe and point out on the map the places where you have had experience of the result of well-sinking? I have some memoranda which I made on the occasion of my visit to Mount Browne, to report on the means to be adopted to avert another water famine there. These memoranda are as follows:—

Memoranda on wells beyond the Darling.

Mount Stuart Block, near the Queensland border. Thompson's well, 5 miles south-west from Tippaburra, 134 feet deep, ample supply of water, which rose 37 feet in shaft, good drinking water. Terawinda Plains Block, No. 2, Speed's well, 22 miles S.E. from Tippaburra, 129 feet deep, ample supply of water, which rose 20 feet in the shaft, good drinking water. Scott Bros., Hermitage Block No. 2, 4 miles N.W. of Tippaburra, 130 feet deep, 25 feet bore at bottom of shaft, 8 feet pure water in the bore, said to be the best in the district. Scott Bros., Hermitage Block, 14 miles from Tippaburra, shaft 190 feet deep, bad water and the supply only 200 gallons per diem. Hermitage No. 2, shaft put down by miners at Tippaburra, 200 feet deep, water rose 20 feet, considered ample supply. Chinamen's well, about half a mile from Milparinka, on the Evelyn Creek, about 150 yards from bed, 65 feet deep, two drives of 10 feet each, supply under 70 gallons per hour, probably soakage water. Government well, Milparinka, about a mile north of the town on the bank of the Evelyn Creek, also soakage water. Pimpeira, C. Butcher & Co., 130 feet down (dry), 48 feet of clay (yellow), 20 feet of drift-sand (white), 20 feet of sand (yellow), 30 feet of dark-red ironstone, pebbly drift full of quartz lumps; dark-red pebbly drift, all water-worn, then a layer of white clay 4 inches thick, then dark heavy drift, quartz pebbles; left off in light-yellow sand (dry). Whampah waterhole, probably the finest in the back country, 2½ miles long and 26 feet deep; situate 2 miles on our side of the Queensland border.

I called attention to the necessity for immediately reserving the waterhole, and having a township reserve about it. It is a very valuable supply of water, and the creek itself might be utilized still further, as there are several other waterholes in it which, by being improved, might be made good use of. The Whampah waterhole is situated on the main road from Tippaburra to the Queensland border. It is capital stock country in the locality.

Sturt's Depôt, Glen Run, well, 80 feet deep; rise, 40 feet; first-class water; supply estimated at 10,000 gallons per diem, that is 1,000 gallons per hour for ten hours' bailing.

The peculiarity of this part of the country is that the soil is very firm, except where there are frequent ridges of sand running N.E. and S.W. It is firm pebbly soil, carrying salt and cotton bush, and an inch of rain will cause the creeks to run for 70 miles, while in much of the Darling country it takes 3 inches of rain to fill a tank. Evelyn Creek runs nearly 80 or 90 miles after a fall of an inch and a half of rain. The other creeks run in the same way.

Mount Browne well, 190 feet, fresh water, not yet completed. Rocky Glen well, 200 feet, very small supply, but good drinking water. Rocky Glen, 310 feet, dry. Blackwood No. 6, 100 feet.

This well was unfinished at the time when I was there, but I have since heard that it has been completed, and that a supply of good water was struck.

3592. *Mr. Gipps.*] What is the character of the strata in the wells? Cretaceous. 3593. trata.

Mr. H. A. Gilliat. 5 Mar., 1885.

3593. What is the bottom composed of? I do not know. Some of them have obtained water in the drift below a strata of pipe-clay.

3594. *Chairman.*] Is there a porous gravel bed at the level to which the water rises, through which the water escapes? Not in any of these wells that I have examined. The water is found in the cretaceous beds. There are a number of granite bows; water is not found anywhere in them.

3595. Do you think that the water in the wells to which you have referred stands at the same level in all of them? I think so.

3596. Is there any difference in the height of the water at different seasons? Not that I am aware of. There is another well on Manaly block, which was put down in a good season by the then lessees—Messrs. Geyer and Hamilton. Having plenty of water in the creek at the time they did not make use of it, but during the first dry season they sent a number of sheep to the well, with the result that they lost 5,000 or 6,000, the water being poisonous. The water has not to my knowledge been analyzed to ascertain what the poisonous element is.

Wells in Western District.

3597. Can you give us any information with respect to wells in the Western District? On Mombah station—the property of the Sir John Elder Pastoral Company—one of the largest in the Colony, they have gone in largely for wells fitted with steam pumps. The manager forwarded me a tracing showing the positions of the different wells and the supply of water in them, but the document was destroyed in the Garden Palace fire.

Under-ground supply.

3598. What are your opinions generally regarding the source, quantity, depth, and direction of flow of the under-ground supply west and north of the Darling? I do not think that we are possessed of sufficient data to enable us to form any opinion on the subject. I have not seen anything to indicate the presence of underground streams. I have made no tests to ascertain whether such streams exist, but I purpose this season, if possible, to make a test, by selecting a spot where there are a number of wells in close proximity to each other, and staining the water in one of them with aniline dye. If there is any under-current, it may be indicated by the appearance of the dye in one of the other wells.

Wells between Lachlan and Darling.

3599. Have you had any experience of wells in the country between the Lachlan and the Darling? There are a number of wells on different stations near the Booligal and Wilcannia Road; the average depth of that line is about 120 feet, and the water usually brackish, in some cases unfit for stock. An exception occurs at the Jumping Sand Hill, a Government well, about 20 miles south of Mossgiel. Here the water is so sweet that tea made with it requires no sugar.

Under-ground supply.

3600. What is your opinion respecting the under-ground supply in that part of the country? There is an ample under-ground supply, and my belief is that the water gets its saline properties from the strata in which the wells are sunk. The strata are heavily charged with salts. In 1879, I tasted water from the Holy-box well; up to that time it was so salt that no animal would drink it. I collected from 20 to 30 lb. of clean crystals of salt which had formed around the service tank and troughing. I recommended that the well be condemned, and forwarded the statements of people who had resided in the locality from the time the well was sunk; they all agreed that from the very first the water had been undrinkable. At the end of 1883, a tank was being constructed in the locality, and the contractor not having any supply of water for his horses tried that in the well, and found that the animals would drink it; on making further inquiries, I found that there was much more water in the well than there was in 1879; this I attributed to surface drainage. The water was baled out of the well, and that which came in afterwards found to be good enough for stock. There are several other wells in which the quality of the water has improved in the same way.

Saline beds.

3601. *Mr. Gipps.*] Do not you think that the presence of salts in such large quantities in the strata proves that there is no under-current? That is my opinion; I do not expect to find any under-current where

Under-currents.

the water is so heavily charged with salts, but I expect to find good supplies of fresh water below the level of this saline bed.

Legislation.

3602. What is your opinion regarding the necessity for legislation on the subject of water-rights? I think that it is most important—more required than almost any other legislation.

3603. Will you state concisely what in your opinion ought to be the nature of such legislation? I have given my opinion as clearly as I could, in the following addendum to my evidence before the Select Committee on the Pastoral Dams Bill:—

1. Riparian rights.—It may be remarked that any contemplated legislation on this subject should perhaps embrace the anticipated requirements of two classes, viz., Crown lessees, and the owners of the banks of streams. In the first case the Crown is the riparian owner; in the second, the banks have been alienated, and the rights are vested in the proprietors. The latter class is largely represented upon the streams and effluents between the Murray and the Murrumbidgee, to a considerable extent upon the Upper Lachlan, on portions of the Lower Lachlan, the Bogan, the Macquarie, the Martheguy, Castlereagh, Namoi, Gwydir, and Narran, and occasionally upon the more western rivers and streams; on all these latter, however, the riparian rights remain chiefly with the Crown.

2. The height of weirs.—To prevent infringement of the rights of riparian owners, the height of weirs will perhaps require to be regulated by the average flow of the stream in which they are constructed, and to a considerable extent by the position of the storage reservoir. Weirs storing the impounded water within the banks or in the bed of the stream should not perhaps exceed the height sufficient to retain that proportion of the minimum flood of the stream allotted to the weir. When the storage reservoir is without the banks, and the water to be impounded is conveyed to it through a race, without serious loss from soakage, evaporation, or waste, the height may be increased; but in such case the weir should be furnished with sluice-gates, to discharge the surplus supply when the impounding area is filled. In some streams where a minimum flood might run down 50 miles, the ordinary dams placed on the upper stream would impound and waste so much of the flow that it would not reach half the distance. Overfall weirs, with a supply allotted to each in proportion to the height of the flood, would obviate this curtailment of the riparian rights. But this necessitates an agreement, based upon the average of the annual floods, of the impounding right to be allotted to each weir. In streams similar to the Castlereagh, where even after prolonged droughts the waters continue to flow beneath the sand, the weirs may be of different heights, regulated to prevent water wasting over the banks; as after banking up to the level, the surplus water will flow over the weir, to follow its course beneath the sand until intercepted and backed up again at the next weir below. Again, streams exist that for many miles of their course are mere water runs, almost indistinguishable as a watercourse in dry weather, such as the Merri Merri. In the N.W. of the Colony are frequent creeks and small streams, with well defined beds or channels conveying flood-waters for many miles, eventually wasting over great clay-pan swamps or shallow lakes. The varying conditions of these streams will perhaps have to be considered.

3. The management of streams upon which weirs may be constructed.—It may be admitted that, in the absence of exact data upon which the calculations should be based, reasonably approximate ones may be arrived at by competent men. Upon permission having been obtained from the Minister for the construction of a weir, it

may

may seem desirable that two arbitrators should be appointed—one to represent the Crown, and one elected by the riparian owners—to regulate the height and the proportion of the flood-water that may be allotted to the weir, and also the dimensions of the impounding area. Or, each stream, on application from the majority of of the owners or lessees, may be constituted a Water Trust, with a Chairman appointed by the Crown, and an elective Council, with power to regulate these questions, and within certain limits to collect rates, either by assessment or upon the proportion of water stored at each weir. Or, Local Courts might be constituted under a Local Government Bill with similar powers. Mr. H. A. Gilliat. 5 Mar., 1885.

4. The distance between weirs would be regulated upon the same averages of flow, or, in other words, by the proportion of the average annual flood-water to be distributed among the riparian owners of the stream.

5. Pollution.—With respect to the pollution of impounded water, if the storage reservoir is within the banks of the stream the provisions against it can hardly be too stringent. The washing of one or two hundred thousand sheep may involve soiling water of owners below for years, of short supply, with no heavy flow to clean out storage reservoirs. Where the reservoir is beyond the banks, and filled by a race from the weir, the restrictions might be modified to admit of sheep-washing.

6. Construction of weirs.—With respect to the construction of overfall weirs, although in favour of a large discretion being allowed in the selection of material, great misapprehension appears to exist as to their cost relatively with the earthen dam commonly adopted in this Colony. Timber crib weirs, similar to those built by the timber men of Maine and Canada when the spring freshes are insufficient to float their winter logging down, can be put on any of our timbered streams at quite as low a cost in the long run as the majority of the earthen dams. Over a large portion of the Western Districts gypsum is found in large deposits; this, calcined and mixed with sand and water, and run into moulds, where it sets in a few seconds, would make a cheap and durable facing for weirs. Only when it is shown to the satisfaction of the Minister that suitable material cannot be obtained for the construction of weirs should the earthen or any dam be permitted, and to meet such cases the law regulating the by-wash might be carefully considered, with a view of correcting this most fruitful source of waste and infringement of riparian rights, and may perhaps usefully include regulations for its dimensions and construction.

In conclusion, there can be no question of the urgent importance of legislation which will encourage and promote the widespread storage of water, but at the same time it should be so thoughtfully directed as to procure for the Colony the lasting benefit of its being carried out on sound and economic principles.

THURSDAY, 19 *MARCH*, 1885.

Present:—

Mr. BARTON, M.P.,	Mr. GIPPS, C.E.,
Mr. DONKIN, J.P.,	Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E.,	Mr. MURRAY, M.P.,

Mr. M'MORDIE, B.E., C.E.

W. J. LYNE, Esq., M.P., President, in the Chair.

Mr. Arthur Blomfield, of Murranumbla, examined:—

Mr. A. Blomfield. 19 Mar., 1885.

3604. *President.*] Where do you reside? At Buckley's Crossing, Cooma.

3605. Are you acquainted with the country in the neighbourhood of Snowy River and Kiandra? Yes, I have been for many years.

3606. Have you heard that a survey is being carried out with a view of ascertaining whether it is possible to divert the waters of the Snowy River into the Murrumbidgee? I have seen it mentioned in the papers.

Snowy River.

3607. What is the nature of the country between the head of the Snowy River and the head of the Murrumbidgee at Stack's Creek? That is close to Cooma. The country is composed of heavy ranges and plains all the way between there and Kiandra, with belts of timber.

Nature of country.

3608. Kiandra is on the Murrumbidgee? No; it is on the Eucumbene.

3609. Have you any knowledge of the country between Eucumbene and Stack's Creek? Yes; it is timbered ranges and open plain, partly granite and partly trap rock.

3610. Is it very rough country? In some parts it is rather hilly.

3611. Do you consider that it would be possible without any very large cost to bring the water through that country from Eucumbene to Stack's Creek? I think it would be very practicable.

Division from Eucumbene.

3612. You have never taken the levels? No.

3613. Do you think that they would be favourable? Yes; it is rising ground all the way to Kiandra. The water would come down with tremendous force.

3614. What distance do you think it is from Eucumbene at the point at which the water would have to brought down to Stack's Creek? I fancy you would have to bring it from a station called Eucumbene. The other part is too rough and mountainous, and the fall would be too great. I think that by following the valley a sufficient fall could be obtained. The force of the water would be tremendous.

Distance to Stack's Creek.

3615. If you struck the river at that point, would it take in any of the large tributaries? Not that I know of, but there are a great many small streams—never-failing ones—which run into it.

Small streams.

3616. I suppose it would take a great quantity of the Snowy River water? Yes; and at times that river swells very much, particularly in the spring, when the snow is melting, and after a storm.

Quantity of water.

3617. From your knowledge of the stream, is it tolerably continuous? Yes.

3618. From the melting of the snow? Yes.

3619. At what time principally does it melt? In spring.

3620. How long does it last? The heavy floods last a day or two generally, and occasionally the river overflows its banks.

Floods.

3621. How long does the melting of the snow last? During the whole of the spring and a great part of the summer. There is snow on Mount Kosciusco now—there always is a little to be seen. The hills and the swamps about there are so spongy that the ground is full of water.

Melting of snow.

3622. I suppose that in the neighbourhood of the Snowy River the water, instead of running away all at once, gradually soaks out? Yes; and it keeps up a constant supply all the year round.

Constant supply.

3623. What I want to know is, whether a sufficient quantity of water runs down the river in December, January, and February to be of great benefit in any ordinary year, if turned into the Murrumbidgee, so as to keep a constant stream in that river? Undoubtedly.

3624. All through the summer? Yes.

3625. *Mr. Barton.*] The great bulk of the snow melts on the hills in about eight or nine weeks? It all depends upon the rainfall.

3626.

Mr. A. Blomfield. 19 Mar., 1885.

3626. Do not the miners there reckon on having water for nine or ten weeks from the melting of the snow? Yes; but there is snow still on the hills—there is always snow there; I have seen 10 feet of snow at Christmas; that is on the eastern side.

Duration of melting of snow.

3627. *President.*] Can you tell us the distance the water would have to be carried in bringing it from the Eucumbene to Stack's Creek? I should say somewhere about 20 miles.

Distance to Stack's Creek.

3628. Do you think it would be practicable to divert the water from the Eucumbene into the Murrumbidgee by a more direct and less costly route? That is a difficult question to answer—it is a question for a surveyor.

3629. How far is it from the Eucumbene to Stack's Creek, the way the water would have to come? I hardly know; I suppose about 25 or 30 miles. I can ride out there in half a day.

Distance Eucumbene to Murrumbidgee.

3630. How far do you think it is by the most direct route from Eucumbene to the Murrumbidgee at the other place you mentioned, without coming to Stack's Creek? It all depends on what point you would start from.

3631. Can you give us any idea? Not without knowing the route.

3632. I suppose you know the whole of the country up there? Yes, pretty well, between the mountains and Cooma.

Storage of water.

3633. Do you know of any spots which offer natural facilities for storing water? No, I could not say that I do, not being sufficiently acquainted with what would suit for that purpose.

Natural basins.

3634. I mean natural basins, where with a moderate expenditure water could be stored? An enormous quantity could be stored in and near Kiandra. Large quantities are stored there for sluicing.

3635. You do not know any particular spot, such as what they call the Gulf? I have not been at the Gulf. I fancy that the country about Four-mile, near Kiandra, would suit.

Inspection of routes.

3636. *Mr. Franklin.*] Do you think this Commission could gain any advantage by making a personal inspection of the alternate routes? I think so. There is nothing like looking at the place for yourself.

3637. Which would be the best place for assembling? Cooma.

3638. How can that be best reached from Sydney? By train to Bungendore, and thence by coach. If it was known that you were coming, a number of people would meet you and drive out with you to Kiandra, where you would have to take pack and saddle horses.

3639. Which is the best season for making such a visit? About the beginning of January.

3640. Is it not practical later than that? You can go this month or next, but I should not advise you to go so late in the season. There have already been frosts even down on the plains.

3641. As it is a rough country, you would not recommend that a very large party should go? It is not a rough country; it is a very pretty country, presenting a mixture of open and timbered land.

3642. Could all the appliances for a camp be obtained at Cooma? Yes. I could supply a couple of pack and a couple of saddle horses, and we could wire in advance for provisions.

3643. *Mr. Donkin.*] How long did you say it takes to go from Bungendore to Cooma? Twelve hours or less.

3644. Do you think you could get good evidence by visiting Cooma? I think so.

River at Eucumbene station.

3645. Did you say that the river at the Eucumbene station is a large stream? No, a small one, but it never ceases.

Discharge.

3646. *Mr. Franklin.*] You have never gauged the discharge? No; the country is so well watered that we do not take much notice of the rivers.

3647. Then you do not really want the surplus waters, so far as agricultural and pastoral purposes are concerned? We do not; we have sufficient spring water.

Utilization of waste water.

3648. *President.*] Do you consider that the waters of the Snowy River would be of any service on the Lower Murrumbidgee? I fancy that they would. It would be a national benefit to utilize the water which is now being wasted.

3649. Do you know the Snowy River down to the sea? No; I have been along the river to just below the Victorian border.

Country on Victorian side.

3650. Is there any large amount of good land on the Victorian side? No, it is wretched mountainous country.

3651. Then the water going through there could not be utilized in Victoria? Not for many miles, except to keep open the channel to the sea.

Providence Flat.

3652. *Mr. Gipps.*] What is the length of Providence Flat? I suppose that from the township down to Russel's it is 2½ or 3 miles.

3653. What is the breadth? That I could hardly say.

3654. But it is a large area? Yes.

Breadth of Eucumbene.

3655. What is the breadth of the Eucumbene at Providence Flat? It is very narrow indeed. At low-water-time it is not more than 10 yards wide, and at high-water-time about 50 yards.

Depth.

3656. What is the depth of the water in flood-time? I could not say.

3657. Could you cross it in a buggy? No; there may be 30 feet of water running down at such times.

3658. What is the average depth in summer-time? From 2 to 4 feet.

Current.

3659. What kind of current is there? It is strong, and the water is very clear.

Country near Mount Kosciusco.

3660. Do you know the country in the immediate vicinity of Mount Kosciusco? I have not been to Kosciusco.

3661. Have you crossed the Snowy River in the vicinity of Kosciusco? Yes.

Examination of streams.

3662. Is it a large river? No, a small one, as big as the Eucumbene.

3663. Do you know the Burrangobuge River? I may have crossed it without knowing the name.

3664. Would you not advise the examination of all these streams? I would strongly.

3665. *Mr. Donkin.*] Would you advise the Commission to visit that part this month or at the beginning of next year? It is getting rather late to attempt it this year. The Surveyor-General and his daughter went out in January, and were kept there three days.

Rain-gauge.

3666. Have you kept a rain-gauge? No; but I should like to get one.

THURSDAY,

THURSDAY, 31 *MARCH*, 1885.

Present:—

MR. DONKIN, J.P., | MR. LYNE, M.P.,
MR. M'MORDIE, B.E., C.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. James M'Laurin called in and examined:—

Mr. J. M'Laurin. 31 Mar., 1885.

3667. *President.*] Where do you reside? At Yarra Yarra.
3668. That is in the Germanton district? Yes.
3669. How long have you been a resident of the Colony? So long that I almost forget—about forty-seven years.
3670. In what part of the Colony have you resided the greater part of that time? Principally in the Murrumbidgee district—what is called the old Murrumbidgee district, between the Murray and the Murrumbidgee.
3671. In what part? I have been for a considerable time, fifteen or twenty years, on the Edward.
3672. Had you any station property there? Yes.
3673. I believe you were the first discoverer of the Edward River? I believe I was. Edward River floods.
3674. About what year was that? I think it was in October, 1840.
3675. Have you had any experience of large floods? Yes, I have seen a great many floods on the Murray and Edward.
3676. What extent of country is flooded by the Edward and the Murray? The Edward takes its rise out of the Murray—for it is a branch of the Murray you may say—about 20 miles above Deniliquin, and runs for about 150 miles, after which it joins the Murray again. The Tuppal is another branch, which runs out of the Murray a little below Tocumwal. A little above Old Tocumwal there is a sandy creek which runs out of the river. Mr. Mooney made a cutting into the Tuppal Creek below Tocumwal. Cutting at Tuppal Creek.
3677. Who was Mr. Mooney? He was the owner of the Barragama station.
3678. And he made a cutting from the Murray into Tuppal Creek? Yes, a cutting something like that of the Yanko, only a short one. The country is lower some distance back than it is on the banks of the river.
3679. *Mr. Donkin.*] Where does the main body of water run out? To Jarapna Creek. I think the Gulpa Creek is the oldest channel course; it runs deep the whole way, until it comes into the Edward at Deruliman, where Boyd and Company formed their head station before they formed Deniliquin. A great many creeks run out of the river Murray, and the whole of the country, excepting the sand-hills, is lower than the river banks. Gulpa Creek.
3680. *President.*] That is near the outlet of the Edward River? Yes, it is all lower up to about somewhere near Baruga station. My reason for saying so is this: that in flood-times a rise of an inch on the river bank gives a rise of 3 or 4 feet some distance back. Some thirty-five or forty years ago the Edward ran into swamps for about a mile, and eventually formed a creek. When Captain Sturt went down the Murray to Adelaide he could not get along for the swamps, and he cut a place to get his dray to the river, to cross to the Victorian side. That cutting, which I call the Broken Bank Creek, became larger year by year, until it formed a deep channel for about a mile and a quarter down the Edward River: that is the reason why the Edward River rises so much earlier now than in years gone by: the action of the water has made a deep channel. When I first saw the Edward it was impossible to get a steamer up it, but now a steamer can be taken right up into the Murray. Country near the Edward. Broken Bank Creek.
3681. *Mr. Donkin.*] Is navigation possible now from the Murray up the Edward to Deniliquin? Yes, in flood-time. Navigation.
3682. *President.*] To what extent was the country flooded during an ordinary flood forty years ago? You see here on the map where the Tuppal Creek flows out from the river. Well, the Tuppal may be flooded for a mile or two on the north side, but there is a higher strip of land between that and the Billabong running right down to Deniliquin. I have seen the flood-water extend from a mile and a half on the north side of the Tuppal right across the Murray for about 8 miles, I suppose, on the Victorian side. That would be about 20 miles altogether. Flooded country.
3683. Were the floods regular? About forty-one years ago we had high floods on the Murray; we used always to look for a flood at the melting of the snow, and I have seen the floods high until December or January, so that you would have to go to Albury to cross unless you crossed in a bark canoe.
3684. But were the floods pretty regular? Yes, for four or five seasons, and then we had a few dry seasons. I think, if I remember rightly, that in 1844, 1845, and 1846 we had pretty high floods; they were very high in 1844 and 1845. Regularity of floods.
3685. And how long were the dry seasons? All the time I was down there we had twelve or eighteen months of a dry season at a time. Dry seasons.
3686. But did the seasons alternate regularly—two or three dry seasons and then two or three wet seasons? Two or three would be moderately dry, and then for two or three seasons we would have great floods, as far as my recollection serves me. Alternation of seasons.
3687. And over what period did your experience extend? I have known the Edward from 1840, I may say. I lived there most of my time from 1844 to 1855 or 1860, and during that time we had such seasons as I have mentioned. The driest season we had was in 1851.
3688. *Mr. Donkin.*] And in 1852 the big flood occurred? In the latter half of 1851 we had great floods. Black Thursday was on the 6th of February, 1851, and in the following May, June, and July we had heavy rains and great floods on the Murray. Flood of 1851.
3689. *President.*] Do you know anything about a hollow or valley that leads away from the Murray above Howlong? I have been on it in several parts, and I have been told by those who have followed it that it runs down to about Howlong near the Oil-tree—somewhere near to the Tuppal. A great deal of water lies about the Oil-tree. I went out to look at the Quat Quatta with James Day and Company, and we rode through water, at a distance of a mile or two from the banks of the river, all the way to the Oil-tree. Valley above Howlong.
3690. Do you think it would be practicable, by putting a weir across the Murray about Howlong, to divert a portion of the Murray water down to Jerilderie? I think it would, but it would be an expensive work locking the Murray. Weir across Murray.

3691.

Mr. J. M'Laurin. 31 Mar., 1885.

Wells.

3691. But apart from the expense of weiring the Murray, you do not think the expense of sending the water down would be great? If you once got the water high there would be no difficulty about its running down.

3692. Did you ever sink any wells down there? Yes, we had wells sunk for our own use—that was between the Tuppal and the Murray.

3693. Had you to sink deep, or did you get the water at a shallow depth? At one place I think we sank about 100 feet.

Quality.

3694. Was the water good? The water was pretty good at first, but I do not think it remained good; whether it was because we did not use it sufficiently or not I do not know. We sank a well at Curnalla for house purposes and only went about 20 feet down.

Water in creeks.

3695. *Mr. Donkin.*] Was there always water in the creeks? Not in the Tuppal, but there is always water in the Bullatella Creek.

Distribution about Howlong.

3696. *President.*] You think it would be possible, from the nature of the country, if you had a sufficient quantity of water at a higher level, about Howlong, to distribute it about that portion of the country? I fancy there is higher country out near the Billabong again, between this hollow and the Murray.

3697. *Mr. Donkin.*] But from your own knowledge you do not know that the water ever runs down that hollow? No, except it may be from local rains. I have been told that there was a run of water there in very rainy seasons.

3698. Could it be traced? I do not know, unless you had a run of water; then you could.

Weirs and dams

3699. *President.*] Do you know of any reason, in the nature of the soil on the Murray, why weirs or dams should not stand there? I do not know of any reason, unless it is from the immense pressure of water.

3700. But do you not think the soil would be likely to wash away? No; I think that about Howlong

Clay soil.

there is a good stiff clay soil.

3701. Have you been on the Darling? Yes, at Wentworth.

Banks of Darling.

3702. Do you think the banks of the Darling would stand weirs being put across? Well, when I was on the Darling, at the junction—I have never been above the junction—the soil seemed to me to be more porous than that at Howlong.

Weirs in the Darling.

3703. Is it soil that you think would stand if a weir were put across the river, or would it wash away in flood-time? It all depends on the volume and force of the stream. In all that country, if the surface is broken I think the soil will break away by the action of the water. In making dams on the Billabong, people found that if they broke the surface they ruined the dam—that was the reason why they sent the water so far out; if they made a by-wash on the Billabong they would ruin the dam, because if a flood came the whole thing would be washed away by the current.

3704. But suppose, on the same principle, that a dam with a sluice were placed across the Darling and the water allowed to get away by a channel higher up, do you think the dam would stand? From the nature of the country below the junction I should think the dam might stand, and there is this in favour of it, that

Current in the Darling.

the current is not rapid—there is not nearly the current in the Darling that there is in the Murray.

Depth at Howlong.

3705. *Mr. Donkin.*] What is the average depth of water at low tide at Howlong? I think I saw the Murray in its lowest state in 1851, and we had always 3 or 4 feet of water.

3706. You have never seen it a chain of ponds? No, nor do I think any other person has. In 1851 there was a good stream of water—you could just cross on horseback over the sand bank; but of course there was a considerable depth of water in some of the holes. I have never seen the Murray, the

The Goulburn and the Ovens.

Goulburn, or the Ovens, a chain of ponds, although I have seen them pretty low.

Natural basins.

3707. From the nature of the hills about the head of the Murray, do you think there are any natural places where water could be stored by means of not too expensive dams? Well, there are some fine basins on the Murray, but unless you went very high up to some of the branches near the head I think damming the Murray would be a very expensive work.

The Billabong.

3708. What height does the Billabong rise above the Murray from the head of the Yarra Yarra? I do

Fall.

not know; there is a great fall from the head of the Billabong down to the Murray.

3709. Can you give any idea what the fall is? I should say 500 or 600, or 1,000 feet.

3710. From the head of the Billabong? Yes, down to the Murray, because there is a sort of a table-land from the head of the Billabong, and then a great fall. I should say it must be 400 or 500 feet at the lowest, and perhaps more.

Diversion from the Murray.

3711. Do you think it is possible to divert the Murray waters from opposite the head of the Billabong into the Billabong in any way except by damming? I do not think so. You see, from the head of the Billabong to the Murray, I suppose, is about 10 or 12 miles, and it is a very rough, rocky, mountainous country.

3712. Do you think it is possible to go higher up near the junction of the river and get the water at an elevation there that would bring it into the Billabong? Well, my idea is this, that if you want a large supply of water, somewhere near Tumberumba would be the place. The hills are pretty high, but not so high as at the other place. There is a good deal of fall before you come to the hills. I should say that there is 600 or 800 feet of a rise, but never having measured it of course I cannot say exactly.

Natural basins.

3713. Do you think there are natural basins about the head of the Murray that could be utilized in conserving water? I do not know; I have never made an examination. There may be. You know the

Floods of the Murray.

Murray is a river which has, in flood-time, an immense body of water; and a strange thing is that you meet with more dry land near the river than you do some distance away.

3714. That is on the dry bank; there is always a wet bank as well as a dry bank—that is, the water spreads on one side for a mile or so? It is the case on both banks—wherever there is a bend.

3715. *President.*] Did you ever try any irrigation when you were on the Lower Murray? No.

Irrigation.

3716. Have you ever tried it anywhere in New South Wales? I have tried it a little at Yarra Yarra, about the homestead.

3717. And did you find the difference very great between irrigated land and non-irrigated land? The difference of course is that you have a spring all the summer with irrigated land, and if you have a good supply you can have grass or vegetables growing all the summer.

3718. Whereas there would be nothing if you had not the water? As an illustration of what may be done, I may mention that last year I had a general crop in my garden. I have a supply of water in a large dam a mile or so above the house, from which the water is brought in a pipe. The vegetables were just beginning to wither when I let the water on, but after that I had a splendid crop, although I do not think I should have had any at all if it had not been for the water.

Mr. J. M'Laurin. 31 Mar., 1885. Murrumbidgee River.

3719. It would be just the same with grass? Just the same with grass.
3720. You have not been out by Hay towards the Darling? No; I ran the Murrumbidgee down in 1839 from Gundagai to Adelaide.
3721. And have you known the Murrumbidgee ever since? Yes.
3722. Have you ever known it to stop running? No.
3723. Has there always been a good fair stream in dry seasons? Always, as far as I have seen. I have been on the Murrumbidgee, and on the Mutta Mutta, the Murray, and the Ovens. I was on the Murray, the Ovens, and the Mutta Mutta in 1851, and they were always running. That was the driest season I have seen in the Colony, and they were all running a good stream then.
3724. *Mr. Donkin.*] Were there many losses in stock when you were on the Murray? A great many in 1851. Losses in stock.
3725. For want of grass? Yes, and water, because there was no water on the Billabong. The people there had to take their stock to Deniliquin and travel up the river wherever they could get grass. Want of grass and water.
3726. *President.*] You say that an immense body of water passes down the Murray in flood-time: has any plan ever struck you by which that water could be conserved or diverted—you say you do not think it could be done well at the head of the Murray? No, I think Howlong is the place to do it. I think the ground would stand better there, and there is not the fall or the mountain torrent you find further up. At Howlong you have a very high bank on the north side, and a splendid basin from there up to Wodonga. My opinion is that it is quite possible to take the water from Howlong, not only into the Billabong Creek, but north of it. Conservation of Murray flood-waters.
3727. Then you do not think it a feasible scheme to take the water from above Albury and bring it to the Billabong? It would be more expensive, because you would have a tier of high mountains all the way, and if you carried the water in pipes, you would either have to cross the immense gorges, or go right around. Besides we always get plenty of water at Yarra Yarra. I think that if people were not too indolent, they would have no difficulty in saving water. Diversion into the Billabong.
3728. It is not so much for that purpose, as to bring the water into the Billabong Creek? I think there would be great difficulty in bringing the water from the head of the Murray.
3729. Do you know where there is any large basin at the head of the Murray, or any creek where the banks come together in such a way that a dam could be thrown across? I do not know anything about that part. Site for dam.
3730. Do you think it is worth while to inspect that part of the country to see if there are such basins? Well, the head of the Billabong goes into a number of creeks, and although there are basins there, most of them have not a great run of water.
3731. *Mr. M'Mordie.*] At any time of the year? At any time of the year. Of course to fill a large space you require a good watershed.
3732. *President.*] Whereabouts is the spot you think most suitable for diverting the Murray water? Near what they call the Holy Plains, near the upper boundary of the Quot Quot Run. In flood-times the water comes some distance from the river, as far as there are any gum-trees. That is most decidedly the easiest place. You will find a hollow running out from there to the Oil-tree. Diversion point on the Murray.
3733. Have you had any experience of tank-sinking on the Lower Murray? No, none whatever; we had plenty of well water, and had no occasion to sink tanks. Tanks.
3734. *Mr. M'Mordie.*] How often have you known the Billabong Creek to flow into the Edward—does it flow often? Always in flood-time, if it is not dammed; but it has not run below Walla Walla for many years. During 1838, 1839, 1840, and 1841 it did not run. That is at Culcairn, where the railway crosses to Albury. Flow in the Billabong. Bed of Billabong.
3735. *President.*] The Billabong Creek is a large deep creek, well defined, with high banks, that would carry a large quantity of water? Yes; but these last few years there has been very little water—I mean down the creek.
3736. I think you are of opinion that all the country along the north of the Murray up to the ridge above Tuppal Creek could be watered? Yes; and there would be little difficulty in taking the water to the north of the Billabong from the Murray, from about Quot Quot, just below Howlong, at what they call the Holy Plain. It would be a very inexpensive work to let the water into Tuppal Creek at the time of a small rise. It runs in now when the river rises, but if the channel at Moom were deepened more it would let the water in much sooner. Watering of country north of the Murray.
3737. *Mr. Donkin.*] Do you think the scheme is more feasible about Howlong than above Albury? Yes, and less expensive, and it would water the country more effectually. Besides, you have the waters of the Little River and of Mutta Mutta, which are always running. Little River.
3738. It would not benefit you much to bring the water in the way you recommend? No, because I have plenty of water. By making a large embankment on the Victorian side and raising the water you would have an immense supply. About the head of the Murray I cannot give you any opinion.
3739. What is the distance from Howlong to Jerilderie? From 80 to 90 miles, I should think. When I travelled down to Adelaide in 1840 no white man had been from the outlet of the Edward to the junction of the Murrumbidgee—there was not a track of anything. Distance from Howlong to Jerilderie.

SATURDAY, 9 *MAY*, 1885.

At Tamworth.

Present:—

MR. FRANKLIN, C.E., MR. LYNE, M.P., | MR. MURRAY, M.P., MR. M'MORDIE, B.E., C.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Arthur Dewhurst called in and examined:—

Mr. A. Dewhurst. 9 May, 1885.

3740. *President.*] You are a district surveyor? Yes.
3741. Have you resided in this district for any length of time? Since 1858.
3742. Have you had opportunities of becoming well acquainted with the whole district? I have.
3743. Are you well acquainted with the heads of the various rivers above Tamworth—the Cockburn, the Peel, the Dungowan, the Swamp Creek? I have been to their heads, or in the neighbourhood of their heads.

Mr. A. Dewhurst. 9 May, 1885.

3744. Have you any idea of the watershed of these creeks and rivers, that is to say, the area of it? I could not tell you here—I should have to calculate it; I dare say I could give it you near enough for your purpose.

3745. We want to know the watershed of the whole of the water flowing past Tamworth? I understand.

Watershed. 3746. The whole of the water coming by Tamworth comes from the creeks I have named, does it not? Yes. I could give you the watershed of each particular creek; but I may say here that I am not prepared to deal with the question of water supply at all—the Government have given me no time for anything of this sort.

Storage reservoirs. 3747. Do you know anything of these creeks or rivers having any natural basins where large quantities of water could be stored? I never looked for any, but I was shown one the other day by Mr. Stuart; I have no doubt that there are plenty as good as that.

Seven-mile Creek. 3748. What is the site of that basin? The Seven-mile Creek.

3749. What distance from Tamworth? 7 miles. That is the nearest route approximately by which you could convey water.

Storage capacity. 3750. Could a large quantity of water be stored there? Very large indeed.

Expense. 3751. Does it appear to you that the works necessary for the storage of that water would be very expensive? Not very expensive, I think.

Land. 3752. Is the land purchased land? The land is the property of the Crown.

3753. Is it a reserve? It is within the population boundary of Tamworth, and therefore reserved from sale.

3754. Is most of the land in the valleys to the south-east of Tamworth alienated? Only on some of the creeks.

3755. Is the land not alienated reserved, or is it not alienated because it is of no value? Because it is of no value comparatively.

Resumption of land. 3756. Supposing any number of schemes were entered into with these creeks, would there be large quantities of land to be resumed or bought—I refer now to land which would be covered by water in the event of storage grounds being selected at particular points? Of course that is very difficult to say, unless one knows what the nature of the works would be; it is a question of levels. If you were to stop the Cockburn River you would have a very fair amount to pay—some thousands of pounds.

Swamp Creek. 3757. Would there be much land to resume in connection with a work at Swamp Creek? Nothing on that I believe; I think that is about the only creek upon which there would be little or no resumption. Of course if the work were carried out by means of a series of weirs it would flood less country.

Resumption of land. 3758. Supposing these rivers or creeks were dammed and a quantity of water were thrown back over the flats, would that necessitate the resumption of a large area of land? I have already said that that would be the case along the Cockburn in places, also along the Peel and Dungowan.

Advantages from storage. 3759. Is it practicable to store quantities of water which would be of service not only in the neighbourhood of Tamworth, but also further down towards the lower country? I do not think it would be of any great advantage.

3760. What is your reason for thinking so? This is ground upon which I would rather not enter; I have not thoroughly considered the matter. If you were to report what I say now, it might clash with the opinion which I shall have the pleasure of giving you by and by. I wish to consider the matter thoroughly. I have been asked by the Commission—at least I have a circular to that effect—and I prefer that my evidence upon the line you are now taking should be confined to my report in answer to that circular.

3761. Then I am to understand that you have not sufficiently thought the matter out at the present time to permit your giving evidence to the Commission? That is exactly what I wish you to understand.

3762. But you will do so in reply to the circular which the Commission have forwarded? If the Government will allow me time to do it.

Heads of rivers. 3763. Are you well acquainted with the heads of rivers in any other part of the district? I think I know them all; I have been here twenty-seven years.

Walgett. 3764. The country in the neighbourhood of Walgett is entirely different from that in the neighbourhood of Tamworth? Yes, it is.

3765. Flat? Quite flat.

3766. And badly watered? Yes.

Dry creeks. 3767. Are there many dry creeks or ana-branches running through it? A great many, more or less, in the vicinity of the river.

Floods. 3768. These are filled only in flood-time? Yes, the whole is covered in flood-time. I could mark you out the area on the map.

3769. The water runs over the surface, then goes to waste? Yes, we should say it goes to waste; it is not utilized.

Storage on Namoi. 3770. Do you consider that a great deal of water which flows down the Namoi, coming from the mountain ranges, could be impounded and prevented from going to waste? A great deal of it.

Natural basins. 3771. Through the rangy part of your district are there natural basins for the formation of reservoirs and lakes? I am not intimately acquainted with them, but I feel sure that there are.

3772. You could not direct attention to any particular spot in connection with which further investigation could be made to ascertain whether a natural basin does or does not exist? I could not at present.

Underground stream. 3773. Has it ever come within your knowledge that there is any underground stream or spring in your district? Yes.

3774. Could you point out in what part? In the neighbourhood of Millie, in the county of Jamieson, near Narrabri.

3775. Is it an underground stream? Yes.

Depth. 3776. At what depth? I have it not with me at present, but, speaking from memory, I should say from 20 to 30 feet.

Width. 3777. Have you any idea of the width of the stream? I should say, at the very least, 10 miles.

3778. Is the water obtained in drift? It is not a drift; I can hardly tell you what it is; it runs to the westward.

3779. Are there any indications on the surface? None whatever.

3780. How is it tapped? By a well.

3781. By one or more? A great many wells.

Flow. 3782. Has it been tested at any distance from the Barwon? It is running—there is a perfect flow in it.

3783. Artesian? Not artesian.

Rise. 3784. Have you any idea where it rises or comes from? I have not at present. I could find out easily enough by looking at the map; that is to say, I could find out where it does not rise from, and from that I could tell you where it did.

Mr. A. Dewhurst.
9 May, 1885.

3785. Is the water good? It is salt water.
3786. Cannot it be used? Not for domestic purposes.
3787. Is it fit for stock? I doubt it; I am not sure; I have all the particulars, but I do not like to give you these things from memory.
3788. I understood you to say that the stream is pierced by a number of wells—are they using these wells for any purpose at all? They sank deeper, I believe, into fresh water; they got through, but I believe that they had the greatest difficulty and trouble in doing so. Wells. Fresh water.
3789. Have you any idea of the depth to the fresh water? I think that it is about 110 feet. Depth.
3790. Did they get a good supply at that depth? Not sufficient, I think. Supply.
3791. Did they get it at that depth in all parts of the district? I am not sure; my impression is that that is the depth at Boggy Creek; there is a Government tank there. Boggy Creek.
3792. In sinking these wells, did they line them to keep the water out? I forget the way in which the men got through the drift; I think that they slabbed and puddled it, if I remember aright; but I know that they had a great deal of trouble.
3793. There is no doubt, I suppose, that this salt water, or rather the water which becomes salt, comes from the surface higher up somewhere? Yes. Source of salt water.
3794. Do you think that it would be possible to intercept it at a point where it sinks in through the upper strata? I do not know: I should like to know a little more about it before I ventured to offer an opinion on that point; if I knew the section of its bed it would be very easy to settle it. Interception.
3795. Where is Moree? Not far from that point. Moree.
3796. What is the nature of the soil? Black. Soil.
3797. Up to the heads of the rivers? Nearly to the heads; here and there there are sandy ridges. Rivers.
3798. At the heads of these creeks—the Wee Waa and several others, the Big River and its tributaries, is it rangy in the same manner as near Tamworth? There is the great Nandewar range. Nandewar range.
3799. In that range would the same facilities be found for the storage of water? There are plenty of basins. Basins.
3800. Have you any information respecting wells in that part of the district? I know a great deal about them. Wells.
3801. Is there a well at Boolcarol? There are several wells there. At Boolcarol.
3802. Have they sunk them to any great depth? About 60 feet, I think. Depth.
3803. Did they get a good supply? In some cases. Supply.
3804. Is it salt or fresh water? In some cases it is pretty fresh. Quality.
3805. Serviceable for stock? Yes.
3806. Is that distinct from the other line of country which we have been speaking of? Yes.
3807. In the Boolcarol wells is there a flow in any direction? I could not say; it is not artesian water. Flow.
3808. Do you think that throughout the low country in the county of Jamieson, and in the Gwydir district, any good could be done by storing water at the heads of the creeks and distributing it throughout the flat country for stock purposes? It might be useful to the people who own the land. Storage in Gwydir district.
3809. Is the land in most cases good enough for agricultural purposes? It is good enough for anything. Land.
3810. And the only drawback is the want of rainfall? It is the climate—the want of moisture in the climate. Want of moisture.
3811. Do you know anything of the swamp to the north of Mille? That is out of my district.
3812. Do you know the country south of the Namoi? Yes. Namoi country.
3813. Do you think that artesian water is likely to be found there? I know that it is. Artesian water.
3814. In many places? I know of several places. Locality.
3815. Can you indicate any spot? There is the Bando, for instance.
3816. Does the water rise to any height above the surface? It runs over the top of the well, but the supply has slackened. Supply.
3817. What is the size of the well? I forget; it is a large well. Well.
3818. An open slab well? An open well.
3819. Do you know the depth of it? I think that it is about 70 feet; it is referred to in a report by Mr. T. K. Abbott, on wells in the Liverpool Plains. Depth.
3820. Is that the only case of artesian water? No; the water comes into that well from the sandy catchment, where there is no evaporation, at Coonabarabran; that is to say, from the counties of Baradine and White; there is a sandy formation there covering a very large area. Source.
3821. What is the area? Immense; over 1,000,000 acres. Area of sand ridges.
3822. Is it high land? Part of it is high, and part low; there are ridges running through it; it is higher than where the well is sunk; it is the great storage of water for Liverpool Plains.
3823. Do the Brigalow and Borah Creeks run through ridgy country? Comparatively flat country. Brigalow and Borah Creeks.
3824. Are they high enough in the neighbourhood of Coonabarabran to permit of the formation of basins? The difference of the level between the springs at Girrawila and the well at Bando will give you an idea. I should say that it is about 400 feet.
3825. Which way is that artesian water flowing? It flows with the creeks, trending generally north and west. Flow of artesian water.
3826. Are you acquainted with other wells? There are several wells similar to those to be found on the Caspian Sea and in parts of America. Wells.
3827. Are they artesian? I should imagine so; their depth is very great; I could not find the depth at 40 feet; they are full of water to the consistency of thick cream. Artesian.
3828. Referring again to the watershed above Tamworth, is there any extent of country in the neighbourhood of Tamworth which could be irrigated if water were stored at the heads of the creeks? All the Cockburn River farms could be irrigated to some extent. Irrigation.
3829. Have you any idea of the difference in value as between irrigated and non-irrigated land? I have. Value of land.
3830. What would you consider the difference? That would depend on the land irrigated and a good many other things besides.
3831. I am speaking of the class of land in this valley? The best alluvial flats I should think would go to three times their value, at the very lowest estimate.
3832. *Mr. Franklin.*] Have any observations been taken of the average flow of water through Tamworth? No register is kept now.
3833. What is the catchment area of the Cockburn above cultivation? I could not say. Area of the Cockburn.
3834. Is it very large? Very large.

Mr. A. Dewhurst. 9 May, 1885.

3835. If a large body of water were stored above the present line of cultivation and regulated down into the river or courses along the valley, would there be much storage on the present holdings of cultivable land? There would be a great deal of disturbance of course if the water were led through any of the holdings.

Fall of country. 3836. Then by running the water in a true course it is possible that we should come above the surface quickly, although we dam the upper part of the river itself? I do not think that the fall from Moonbie to Tamworth is very great.

3837. Do you not know the fall? The railway levels would give it to you.

Hanging Rock. 3838. There is a large watershed at Hanging Rock? Yes.

Discharge. 3839. Could a discharge of that river be made at any point above Bowling Alley Point without disturbing cultivable areas of land? I do not think that you could get enough water above Bowling Alley Point.

3840. Do you know any point at which it would not disturb present improvements, and where water could be thrown back with a view to keep your river constantly running? I do not.

Neringa Flat. 3841. What is the area of Neringa Flat under cultivation? I could not say.

Population 3842. There is a large population there, is there not? Comparatively small.

3843. They depend greatly, do they not, on the water flowing through the river for all purposes? They have wells.

Cultivation land. 3844. Supposing they could get water by gravitation, there would not be much more land under cultivation? I do not think that any more land would be put under cultivation. I say all this with reserve.

Dam at Seven-mile Creek. 3845. You mentioned a site which you saw in company with Mr. Stuart which is capable of holding a large body of water at Seven-mile Creek—have you any idea of the size of the opening which it would be necessary to dam in order to impound the water? That would depend entirely on where the dam was made.

Opening. 3846. You did not form any idea at the time of your visit? A dam at the point at which I was looking would be very large indeed.

Height. 3847. Would it be a high dam? You could make it as high as you liked to impound more water.

3848. There is no natural depression in the land which would give a basin of which the lowest lip outlet could be taken for dam purposes? I do not think so.

Range between Tamworth and Manilla. 3849. Could a large quantity of water be held back between this and Manilla—What would be the drainage line—would it be the flats of the Namoi, or is there intermediate country? The question is where you would impound. There is a dividing range between Tamworth and Manilla.

3850. Are there any gaps? Yes; the Peel River makes a gap.

3851. Supposing we reduced the fall of the Peel River by a canal, could we get through the range to discharge water on the other slope? No.

Water in sandy area. 3852. With reference to the large sandy area to which you have referred, do they find water in the sand itself? The creeks are dry except in deep water-holes, but you can scratch and find water anywhere almost.

Moree. 3853. *Mr. Murray.*] Do you know anything about Moree? I was never there.

The Meei. 3854. Do you know anything about the Meei, an ana-branch of the Gwydir? I have been there—that is all I can say.

3855. Do you think on the whole that any system of conservation could be adopted in the district which would be beneficial to it for stock and for irrigation purposes? That is a question which I cannot answer at present.

Losses through want of grass. 3856. Do you think that if the people were benefited to a considerable extent, they would be agreeable to subscribe towards the expense, by allowing a rate to be levied upon them commensurate with the extent of the improvement? I do not think so. I may mention casually that in this district losses have been occasioned by want of grass, and not by want of water.

Irrigation of the plains. 3857. If we had irrigation should we not get grass? I do not think that the plains will ever be irrigated; there is not sufficient water to irrigate them.

3858. Suppose that the flood-water of which you have been speaking which goes to waste were stored, would that not be sufficient? I do not think so.

3859. Then you do not think that the labours of the Commission would be of great benefit to this part of the country? I think that they will be of benefit if they only prove that the attempt to irrigate the plains would not be successful.

3860. You think that that is what it will result in? I think that you will not irrigate the plains.

3861. Would irrigation improve agriculture? I think so.

Soakage. 3862. Is there much soakage in the creeks and rivers? In many of them, such as the Cockburn.

Silting. 3863. A good deal of silting takes place with over-shot dams? In some rivers where there is a fall.

Sluice-gates. 3864. With sluice-gates to wash out the silt, there might be reservoirs made suitable for irrigation for agricultural purposes? I think so.

Irrigation. 3865. *President.*] If the upper parts of the valleys were irrigated as we have suggested, do you think that any large increase of the hay and straw produced by irrigation would assist in keeping the stock in the lower parts alive in the dry seasons? It would do something towards it. My opinion on that point may be carried further; irrigation could be carried out on every station to a certain extent—I have seen it done effectually.

3866. In the vicinity of rivers? Yes.

Population. 3867. Is there a large population from this point downwards towards the plains before you actually get on to them? There are no plains between here and Walgett till you get back from the river Namoi.

3868. In the valleys of the rivers is there a large agricultural population? The country from here to Gunnedah is well populated.

Benefits from irrigation. 3869. Do you consider that that population would be much benefited by the conservation and distribution of water which would be used for irrigation? I do.

Local Trusts. 3870. Do you consider that the conservation and distribution of water should be carried out by the Government or by local bodies created for that purpose, the Government lending the money? I think it should be done by local bodies if done at all.

Flood-waters. 3871. *Mr. M'Mordie.*] Have you any information as to the quantities of flood-waters which pass down these various rivers at the present time and which are not utilized? No.

Irrigation. 3872. Could you say what quantity of irrigation could be carried out by means of these flood-waters if they were stored? Yes, I could to a certain extent.

Mr. A. Dewhurst. 9 May, 1885.

3873. At what quantity would you estimate the water for that purpose? I could not go into a calculation of that sort at present. I should have to go through my list of the average rainfalls for the last twenty-seven years.
3874. You have no information as to the quantities of flood-water passing down which would enable you to state what quantity of irrigation could be carried out? No.
3875. What area in the neighbourhood of Gunnedah is occupied by coal-beds? It extends from Gunnedah to Mille, where it squeezes out. Coal beds.
3876. *Mr. Murray.*] It is about 6 feet at Gunnedah? In places.
3877. Through the whole of that country can you obtain water by sinking? I think everywhere. Water in coal beds.
3878. Good water? All good water.
3879. *Mr. Franklin.*] Do you know the Macquarie and the Bogan? Yes.
3880. Do you know the large swamp there? I have not been to the Macquarie swamps.

Mr. Alexander Rogers examined:—

Mr. A. Rogers. 9 May, 1885.

3881. *President.*] Where is your residence? At Attunga.
3882. How long have you resided there? Ten years. I have resided forty years in the northern district, but more east.
3883. Have you property at Attunga? Yes.
3884. Have you any other property in the district? I have a station in the Gwydir District, and another in the New England District, but that is on the eastern slope and is well watered.
3885. What is the nature of the country at Attunga? Dry limestone. Attunga.
3886. Is is ridgy? Yes.
3887. Are there natural basins in these creeks for the storage of water? Very good places for making dams—you could dam large quantities at places. You can find watersheds where the creeks have broken through the bars. Basins.
3888. Could any large quantity of water be stored there? You could store millions of gallons on the Attunga Creek. Storage on Attunga Creek.
3889. Do you know the Peel River? Yes, I know its heads. Peel River.
3890. Is it ridgy country? Yes.
3891. Are there large basins there which could be utilized for the storage of water? Yes, I think so. It would be more expensive there—the soil is of a looser character. Storage.
3892. Is the soil lying back from the Peel River towards Gunnedah rich? Yes. Soil.
3893. Are the floods of any width? Not very wide. Floods.
3894. Are the floods small below the junction of the Namoi and the Peel River? They are larger there.
3895. Are there any farmers? I think not.
3896. Do you know the country lower down between Gunnedah and Narrabri? Yes.
3897. Do you think water could be conveyed in that direction by keeping it at an elevation above the river? I think so; it is a matter of expense; all the farming land could be watered. Farming land.
3898. Do you think that any good would be derived in saving stock by taking water through the back country there? I think that if the supply could be regulated so that the frontage of each run could be irrigated, the losses of stock would be very small. Back country.
3899. You talk of water being taken from the frontage of the runs—do you mean along the river frontage of the runs or along the frontage of the back rivers? I mean such rivers as the Meei, which run themselves right out. The Meei.
3900. What becomes of the water? It runs clean away; some goes into the lower strata, but it runs into the Darling. I am afraid the difficulty would be so great that the cost would exceed the value. If you could conserve water at the head of the Peel River you could take it out on to the large plains, where you could get as much grass on 100 acres as you could get on 1,000 acres elsewhere, provided the water were diverted by a canal from the river on to the back plains. Difficulty of water conservation. Benefits.
3901. Could the station-holders irrigate their lands and at the same time grow hay for their stock? I think so; it would be a matter of industry. Irrigation.
3902. The climate is not of such a nature that it would prevent them from growing these crops? No. Climate.
3903. Supposing this were done, would it induce a farming population to settle on the lands which are not alienated? Yes, there is any amount of farming land between here and Gunnedah, and between Gunnedah and Narrabri, and across to Moree, but it requires moisture. Farming population.
3904. Supposing any scheme of that kind were carried out, should it be done by local Trusts? I do not see how it could be carried out by means of the public purse, on account of such a large quantity of land being purchased; I think it must be a municipal arrangement. In order to irrigate, you would be obliged to pass through private land. Local Trusts.
3905. Supposing irrigation were started from the head of the Peel River and the Namoi, and water were conveyed a great distance down towards Walgett and Brewarrina, the better plan I suppose would be to have a series of Trusts along the river? I think so. Series of Trusts.
3906. The area would be too large to be undertaken by one Trust? Yes, it would be far too large.
3907. Can you give us information as to the porous nature of the land in the centre of your station and on the Peel River? It is not porous in my neighbourhood—it is limestone country. It is not so porous as it is further down the plains. A very small amount of rainfall will grow a crop of wheat near my place. Nature of land.
3908. What is the rainfall? I could not say; it is very small indeed—about the same as at Tamworth, perhaps a little less. Rainfall.
3909. Have you any knowledge of underground streams of water? No scientific knowledge. Underground streams.
3910. But practically? I know that on the flat country down the Meei, and the watercourses across to the Barwon, and on the northern part of the Gwydir, wells have been sunk, and I do not know of any failure to get water at 30 feet in the sandy ridges. It has also been obtained at depths of 60, 80, and 130 feet.
3911. Where does it come from? It strikes me that there is an underground deposit of water. I would not say that there is a current; there is an underground supply lying dormant.
3912. Where does it come from? When the river overflows its banks the whole country is flooded for a distance of 50 miles. I have seen water running into a crack for a quarter of an hour. It runs away into the bowels of the earth and remains there, forming the source of supply which I have mentioned. Flooded country.
3913. Do you find that it will give out at all? Sometimes at 30 feet, or even at 60 feet, the supply seems to fail, but when you sink further the water is recovered. Supply.

Mr. A. Rogers. 9 May, 1885.

3914. Then there is more than one stratum of water, so to speak? I think the water falls away. We have not had a flood in that country since 1879, and the water has been gradually exhausting itself. It is a question of following it down. I have seen water recovered in one of those instances at 3 feet without going through any strata.

Salt water. 3915. Mr. Dewhurst spoke of a stream of salt water flowing towards the Darling? That is further south. I have been speaking of the country north of the Meei. I know that people have wells, as Mr. Dewhurst described them, but that is all I know about them.

Character of soil. 3916. Are there any open or permeable strata along the side of the range which allow the water to sink into lower strata and run down towards the Darling? No, I think not. The character of the soil at the heads of these rivers is of such a nature that the water runs off it; it is all clay; the rock is near the surface.

3917. Does the water follow that rock down into the low country to a point where you lose it? I think not to any great extent.

Big Leather Swamp. 3918. Do you know the swamp shown on the map in the Benarba and Courallie Counties? Yes, it is known as the "Big Leather Swamp."

3919. What is the cause of that swamp? It is an old river-bed—it has been the channel of a big river; it spreads out from 3 to 5 miles. The river is an immense reed-bed now; it is quite dry, but in flood-time it is up to the saddle-flaps in water, and it is about 4 miles across.

3920. What is the nature of the country on the edges? Hard ridges and clay plains, not more than 10 feet in height, with about 4 feet of water, and of course an additional 18 inches would flood the country for 30 miles.

Chasms. 3921. And that water cannot be stored? No. Millions of gallons flow into the chasms I have spoken of, and when the ground is saturated and will contain no more the water flows into the Gwydir.

3922. Is the upper part of the swamp hard land? About Moree it is pretty hard.

Diversion of water. 3923. The water will not sink in there? No. Between Pallamellowa and Moree you might find places at which the water could be diverted and prevented from going into the swamp and becoming lost.

Settlement. 3924. Is there much settlement about the banks of the Gwydir? Not much.

Soil. 3925. It is all good soil? Yes.

3926. It only wants water to make it productive? Yes.

The ranges. 3927. How far have we to go to get the ranges? You do not get into the ranges until you reach Bingera.

Site for reservoir. 3928. Is there any population between Pallamellowa and Bingera? Only a few selectors. There is a good site at Pallamellowa for forming a large reserve.

3929. By damming the river could you conserve a large quantity? Yes, about 5 miles above Pallamellowa.

Width. 3930. What width would you get? Above Pallamellowa you would get high bank and slanting ridges. You could store millions of gallons of water. The total width I should say would be about 1 mile.

Breadth of gap. 3931. How broad would be the gap that you would have to dam? In some places it would be a quarter of a mile wide at the top of the bank.

Current. 3932. Is the stream rapid or sluggish? It is not like a mountain torrent.

3933. And the dam would throw the water back a considerable distance? Yes.

Value of land. 3934. What is the value of the frontage lands on the flats? It is only valuable as pastoral land. If irrigated it would be equal to land in the Clarence district, worth from £30 to £40 per acre—now it is worth only about £2 per acre—that would be its highest value.

Water rates. 3935. Do you think that the people who would be benefited by irrigation and by the distribution of water for stock purposes would be prepared to pay rates? I could not say; I am very doubtful; as far as I know, stock-owners would pay rates, but I doubt whether small holders on the frontages would take to it kindly. I suppose they would in time, when they knew how greatly they were benefited.

People's opinion. 3936. From your practical experience and knowledge, then, you think that the people of the country generally are not sufficiently alive to the great good which water conservation and irrigation would do to them? From conversing with them I think that they are of opinion that it would be a good thing; that is, they are sensible of the advantages of irrigation, still none of them are very enthusiastic about doing anything in the matter.

New England district. 3937. You have a station in the New England district—is that on high land? Yes.

3938. All through that country the storage of water would not be of so much value in the neighbourhood as for distribution on the plains, I suppose—would it be of any service to divert the eastern waters on to the western slopes? It would be too expensive; the streams which you have would, I think, be too small.

Moore Creek. 3939. *Mr. Franklin.*] You were speaking of Attunga Creek—could that creek be connected with Moore Creek at the head so as to increase the volume? I think not; it is surrounded by a high watershed.

3940. The Attunga Creek is not very large? There would not be any object in conserving water there, except to convey it a long way off.

3941. *Mr. Murray.*] You know the neighbourhood of Moree? Yes.

The Meei. 3942. Do you know the Meei? Yes.

3943. Are you aware that it has been dry there for a long time? Yes; unfortunately I have a station on it.

3944. What is the cause of that? The Meei is simply a gutter, and therefore holds no great quantity of water; it drains off and exhausts itself.

Exhaustion of Gwydir. 3945. Is it not being fed now by the Gwydir? The Gwydir exhausts itself above Moree; a great quantity of water is carried away in times of flood; about 19-20ths of the water which comes down is lost. The Big River is lost in the watercourses, and there is nothing left but a small stream in the Meei, which lasts about six or nine months.

Meei cutting. 3946. The Meei, I understand then, is seldom fed by the Gwydir except at high flood? Yes.

3947. Would it be an advantage to open up the mouth of the Meei and let in the water at the same level as formerly? It would be doubtful; I think that you would drain the Big River. The Meei gets another supply from back creeks independently of the Big River.

Mother-of-ducks Swamp. 3948. You know the Mother-of-Ducks Swamp? Yes.

3949. Would it be of any advantage to expend money in deepening and preserving it as a large reservoir for water? That is hardly a fair question to ask. According to my idea, I do not think it would be a national advantage.

Mr. A. Rogers.

9 May, 1885.

3950. If it were done you do not think that the water could be utilized? Except locally. It is in a moist climate, and there is no necessity for it.

3951. Could you apply it to irrigation? I think that the rainfall is sufficient for all purposes.

3952. Is it good agricultural land? When you get a piece of land which is not stony it is very good.

3953. If the water were to be used for irrigation, it would require to be pumped from the swamp to a higher level? Yes.

Pumping on the Gwydir.

3954. *Mr. M'Mordie.*] Do you know of any irrigation in the Gwydir district by pumping? I know of one pumping machine, that of Mr. M'Donald's.

Purpose.

3955. What is the water used for? To water a lot of dry country which in its natural state is waterless.

3956. What distance do they convey the water? They water the country about the Midkin run, a lot of country which could not be stocked with sheep until they got the water to come through.

Distance.

3957. Can you state roughly the distance which they convey the water? Judging from information which I have, I should say 20 or 30 miles.

3958. Is that pumping still carried on? It was being carried on a few months ago; they pump into several creeks, and cut from one to the other.

Success.

3959. Does it pay? It is a success, but I do not know that it pays financially; I know that they are able to run a lot of sheep. Mr. Perry is the manager, and he would be able to give you information on that point. Of course, in the absence of the water, they would be unable to utilize the country. The supply runs through two stations which have joined in the work.

Queensland country.

3960. *President.*] Where is your other station? Near Wecrona, in Queensland.

3961. What is the nature of the country? It is black soil and scrubby.

The Macintyre.

3962. What sort of a river is the Macintyre at that point? Deep, but not very wide.

3963. Is there a constant stream? It scarcely ever ceases to flow.

Water conservation.

3964. Are you below the mountains? Yes, it is all flat country; before you could conserve any quantity of water you must go to the hills above Boggabilla.

Supply from Big River.

3965. Does sufficient water come down the Big River watershed to water the whole of the country in the counties of Benarba and Stapylton? The water could be distributed throughout the whole of that country.

Wells.

3966. Have they wells there? Almost on every station.

Depth.

3967. At what depth? From 60 to 80 feet; at various depths.

Supply.

3968. Is there enough water for use and for stock? Yes.

3969. Where does it come from? I do not know. I know that there is a deposit of water there.

Waterholes.

3970. Have you any wells in Queensland? There is no need for them at my place; there are two creeks out back from the river on my station, and waterholes large enough to sail a boat in—much larger and more permanent than those in New South Wales.

Drought.

3971. *Mr. Murray.*] Has much stock been lost in consequence of the drought in this district during the last seven years? An immense quantity.

Loss of stock.

3972. Can you give any idea of the value of the stock lost in the Gwydir district? Fully one-half of the horned cattle in the Gwydir district must have died within the last four years, and a very large number of sheep.

3973. Can you roughly estimate the value of the stock? No.

Reduction of loss by water conservation.

3974. Could a system of water conservation be devised to save a great quantity of that stock? I am quite certain of it; I am sure it would reduce the deaths to a very small percentage annually; I am sure there is enough water running down in the watershed of the Gwydir to last from one flood to another, could you only keep it.

Water rate.

3975. Speaking as a stockowner yourself, would you be willing to pay some share towards the expense of these works? Yes, certainly I should, so much so that I have consulted my neighbours with reference to a scheme.

Positions of storage reservoirs.

3976. *President.*] You think that it would be better to obtain water by storing it higher up and gravitating it over the country than by pumping it? Yes, I think so, decidedly.

Artificial feed.

3977. *Mr. Franklin.*] If a quantity of water could be thrown over the agricultural portions of the pastoral holdings, do you think that you could grow sufficient feed to keep your stock alive in the worst seasons? I think we could grow enough to save them from dying; I think that each runowner would provide enough from year to year to save his stock from dying. It is a question of industry.

3978. It is not the practice now to grow large quantities of fodder? No, it is not.

Lucerne paddock.

3979. Hitherto you have been depending on the natural grasses in a large measure? I have a lucerne paddock, in which I grew a large quantity of lucerne; two years ago I fed about 150 head of valuable stock, which would have died in the droughts, from a small lucerne paddock, containing between 20 and 30 acres.

Carrying capacity of runs.

3980. Suppose you had a canal, from which you could gravitate a supply of water through open channels to various holdings, would you be able to grow fodder to any large extent to feed stock? Most unquestionably; the carrying capacity of the runs would be made very much larger.

Low sand-ridges.

3981. *President.*] Have you any other information which you think would be of value to the Commission? I should like to say that north of and along the edge of the Big Leather watercourse there is a chain of low sand-ridges, commencing at or near the Gin Waterhole, where the road from Meroe (on the Mehi) to Benarla (on the Gil Gil) crosses the Big Leather watercourse. West of this road and north of Big Leather those sand-hills commence and run in a line at intervals of a mile and a half, sometimes 2 miles apart, from east to west, on the northern edge of the Big Leather, a distance of 7 miles. Water is found on each of those sand-ridges, at various depths of from 14 to 40 feet, in very large supply in some cases, in others a medium supply, and some less. In no case are those ridges or patches more than (I think) 24 inches higher than the level of the surrounding land; the centre of some of the best are depressed in the centre, being a lagoon when the country is flooded. The first of those ridges I allude to was selected about 1882 by a man named Miller, being 80 acres; he opened a well; at 20 feet got water; he having no stock, a neighbour who had no water in 1883 rented the well, made it larger, and for six months watered about 600 head of horses and cattle daily without exhausting or lowering the supply; the stock, at the end of the time mentioned, were taken off to their run. In 1883–84 travellers could not get on for the want of grass; a great number of people went to the watercourse with their cattle and horses, chiefly working stock. There were selectors and others also at this place of refuge. At the time my story commences there was grass, such as I described in my evidence to-day, for several miles around, so that a large number of stock could get food. Five wells were sunk and slabbed on Miller's 80 acres, water being drawn daily from

Mr. A. Rogers. 9 May, 1885.

from each well at the same hours, to water, perhaps, 2,000 head of large stock. This continued until the drought partially broke up, in July, 1884, after which the stock went to their respective homes. The water is lying now useless in its buried bed. Macdonald, selector, and Mackenzie, selector, are lower down, or west, all on the north boundary of my Meroe run, so that I know what I am informing you about. Then we get west to Bucknell's Crinoline Wells, which it is said would water 60,000 sheep. This is, I think, the most western, and is about 7 miles, or perhaps 9 miles, west of Miller's five wells. Those are a few of the names and the most important ones, but there are others betwixt, men of smaller means, who have not developed the water supply—indeed none is fully developed. I do not know that this will assist you in your great inquiry, the most important which has or perhaps ever will be entrusted to a Commission.

Bucknell's Crinoline Wells.

Water conservation on Liverpool Plains.

I should also like to say a few words with reference to the question of conserving water for supplying the dry open parts of Liverpool Plains, in the direction of Cox's Creek and the land on the north-east bank of the Namoi as far as near Galathera Plain. The natural watershed is that of the Peel, Namoi, and Manilla rivers, which drain from north to south a watershed of nearly 200 miles around the range, to the most southern branch near Crawney. The northern branch of this area or Manilla River is near Mount Lindsay, as you will see by looking over your map. A dam below the junction of the Peel and Namoi Rivers, at some point near Keepit or Carroll, would intercept all the waters of this immense watershed which comes down in great volume in flood-times and runs down the Namoi, and is lost to the Liverpool Plains district. Above the junction of the rivers above named irrigation could not be carried out for pastoral purposes to any large extent, the features of the country being contracted by the mountain ranges running to the very banks of the rivers in places. This is especially the case up the Namoi and Manilla. On all the three rivers upwards where there is a farming population, the river flats being narrow, a small scheme of conservation might be arrived at for their special benefit. The large supply I contemplate below the junction would supply the Namoi flats on both sides to Narrabri, where the agricultural land ceases to be so plentiful as it is from Narrabri up to Gunnedah; but still there is a large area of wheat-growing land north and east of Narrabri only wanting a small amount of moisture to assure good wheat crops; as for hay for stock there would be no difficulty about growing on each run enough to feed stock in years of drought, such as 1884. I fear that I have drawn on your patience, but trust you will accept as excuse the desire I feel to afford any information and opinions I have formed on your interesting inquiry. If you have got better information, I shall not consider my trouble wasted in not being able to give a greater amount of information. If at any future time I can be of any use to assist your Commission in the way of obtaining local information, kindly command me.

Dam near Carroll.

Taxation.

3982. Do you think that the pastoral holders would submit to taxation equal to the amount of their present losses from drought in order to prevent future losses—do you think that they would voluntarily assist the Government in establishing Water Trusts? My impression is that they would. My experience is that pastoralists do not grumble at anything which is reasonable and which is for their benefit as well as for the benefit of others. We have several taxes to pay now entirely outside of those which are paid by other people in the Colony. It would be too much, however, for me to say authoritatively that they would pay such a tax as that to which you refer.

3983. If you could be assured that, by a well-considered scheme, you could in future depend on water supply sufficient to produce the necessary quantity of artificial food, would you voluntarily submit to taxation? For my part I should be very glad, as far as the small station which I have in the district is concerned, to pay a very high premium for a constant supply of water apart from irrigation.

Nature of soils.

3984. Do you know the nature of the soil on the banks of the rivers in this district? There are various soils; there is a stiff clay which is good for damming, and a black friable soil.

3985. Is the nature of the soil along the banks such that it would be impossible to erect weirs? In all cases of which I know in which weirs, tanks, and dams have been made they have held the water splendidly. There is no doubt about the holding capacity of the soil.

Silting.

3986. Have you noticed any great silting up at the back of dams? Yes, if they are not protected they will silt. If the water is carried well away past the dams they do not silt up. If the soil is loose and a great many stock come to water the dams will silt up very fast, but we generally put in a pit to catch the silt.

3987. Do you know of any cases in which under-sluices have been provided to carry away the silt by scour? I am not sufficiently well acquainted with damming to be able to say; our dams are made in a very primitive style.

Stone.

3988. *Mr. Murray.*] There is not much stone on these plains? You cannot get sufficient to put around your fireplaces.

Mr. William Springthorpe Dowell called in and examined:—

Mr. W. S. Dowell. 9 May, 1885.

3989. *President.*] Where do you reside? At Tamworth.

3990. Have you resided there for any length of time? Over twenty-five years.

3991. You know the valley of the Peel? I know most of the district—200 miles in one direction and 100 miles in another. I know the country as far as Walgett on one side and Armidale on the other.

3992. How far north and south? Not a great deal north, and about as far as Murrurundi to the south.

Peel River.

3993. Do you know the heads of the Peel River? Yes.

Water conservation.

3994. Have you given much attention to the subject of water conservation? Yes.

3995. Have you looked at the heads of the rivers with a view to the conservation of water? Yes; I have often thought that a large quantity of water could be obtained for the supply of various towns, such as Tamworth and Gunnedah, if water were stored at the Bendemeer. There is there a constant flow of water; it drains a great portion of the New England country, and it is full of springs; it is nearly 2,000 feet higher than Tamworth.

The Bendemeer

Conservation and distribution from the Bendemeer.

3996. What are the facilities for the storage of water? I think you could bring it from the river, or put it into large basins, bringing it along by canals and distributing all over the Liverpool Plains. Having such a great elevation, you could bring it down in the ordinary digger's ditch on a large scale to the various portions of the plains in which water would be required.

3997. It would be a means of supplying Tamworth as well? Yes.

3998. Do you think that a supply by gravitation is better than one by pumping? A great deal, in my opinion.

Mr. W. S. Dowell. 9 May, 1885.

3999. Then you consider that there is a sufficient supply for drainage and for storing water to give a supply to the whole of the valley of the Peel? I think that you might say that there is an inexhaustible supply in the Bendemeer; you could lead it in almost any direction by means of canals and reservoirs for the purposes of water supply and irrigation. Independently of a large quantity of water being stored in this way, I think that artesian wells could be got in many places in the neighbourhood. There is one at Tamworth, which, with little more expenditure, could be converted into a large source of supply. I will hand in to the Commission an article I wrote to the Tamworth newspaper on the subject of artesian wells. I think you will find in it some information about a well sunk by Mr. Paterson, of Calrossy. (*Appendix* V.) Artesian wells.

4000. Have you a farm here? Not now.

4001. Have you had a farm? I have.

4002. On the flats of the Peel? On the river.

4003. This country is subject to periodical droughts? Very much. Periodical droughts.

4004. I believe it is impossible to grow any produce? The crops are materially lessened through the droughts, but we generally manage to grow something.

4005. Would there be a great difference between the growth now and the growth you would have if you had water to irrigate the flats? A great difference in favour of larger crops. Irrigation.

4006. What would be the proportion? It is hard to say. You could grow lucerne here all the year round. It is a profitable crop for stock, and you would be able to feed your stock without any labour. Lucerne.

4007. The lucerne crops could be converted into hay if necessary? Yes; or you might give the stock green feed, which would be cheaper than feeding them with hay. Feeding stock.

4008. Supposing there were a market for hay in the lower country in times of drought, that would make the crop profitable? Yes. I may say that, in my opinion, the hills hereabout are full of water; there are springs in many of them, and in the high parts water is constantly bursting out. All this water tends towards the lower levels. Market for hay. Springs.

4009. Do you know of any case in which one of these springs has been utilized? I have utilized one myself—that is Levy's spring—I obtained water from it when I was burning lime. It is about a mile and a half from Tamworth. Levy's Spring.

4010. What quantity of water? I believe there is any quantity of water there. Supply.

4011. You never tested the daily discharge? Only for daily use.

4012. Supposing the Commission sent an engineer here to obtain information respecting the various heads of the Peel River, could you direct him to the particular spots where he would be likely to find natural basins? There are plenty of such places at the head of the Peel River. Natural basins.

4013. You have seen them? Yes.

4014. You could give the information to the engineer which would direct him to the points? Yes.

4015. *Mr. Franklin.*] Do you think the constant supply of water towards Bowling Alley Point would induce more cultivation on the Nemingа Flat? Yes; but I think the great source of supply is to be found in Bendemeer River. Constant supply from the Bendemeer.

4016. That supply does not reach Tamworth? It goes through the country at the back of Rogers' station and comes in at the junction of the Manilla.

4017. How is it that there are chains of waterholes in the Namoi? The water is still travelling down, but it loses itself underneath. Unless there is a very large fresh of snow or other water it is not connected on the surface. Current of water.

4018. If we could retain the water which is constantly discharging from the Bendemeer and discharge it from a higher level on impermeable ground, we could save a great deal of waste that takes place in the Namoi? Yes, I think so. Distribution.

4019. *Mr. M'Mordie.*] Is there impermeable ground? There are plenty of good stiff clays. Stiff clays.

4020. On which side of the Namoi would it be placed to convey any water stored on the higher levels? On the northern side.

4021. It might be conveyed many miles over excellent land? Yes, you could take it across the Breeza Plains. Breeza Plains.

4022. But we should have to cross from the northern to the southern side to do that? Yes.

4023. Do you know the gap through which the Peel River runs its course to the Namoi? I do not know of any range in the course of that river, and I know it from its head to its junction with the Namoi. The Peel River course.

4024. Do you know of any part of the Peel River below Tamworth which is favourable for the damming and the discharge of water to the plains on the southern side? There are plenty of places between Tamworth and Bective. There is a good place about 9 miles from here and another place about 13 miles. I do not see why water could not be stored just below Summer Hill. Storage on Peel River.

4025. Having fixed this place in your mind, do you know of any drainage line by which a canal could be carried? You could carry it along the low range of country on the Liverpool Plains and let it flow all over those big plains through Breeza. Distribution.

4026. Down towards Gunnedah? Yes.

4027. And towards the Brigalow Creek? Yes. I think it would be well worth the while of the Government to test these limestone ranges and see what water they contain. Limestone Ranges.

4028. *Mr. Murray.*] Should we not injure the people on the Namoi if we diverted the course of the Macdonald? I do not think the waters of the Macdonald could be exhausted. I have noticed good floods of water in the Macdonald and scarcely any in the Namoi. The Namoi frequently rises through local rainfalls. Supply of the Macdonald.

4029. At what point of the Macdonald would you discharge it? Where the railway crosses.

4030. How many miles is that from here? About 30 miles.

4031. *President.*] And where would you go from Tamworth? I would go to Attunga and give the Peel River Company and the Manilla the benefit of the water.

4032. Do you know where the Mooki heads? I do not know where it heads—somewhere through the Breeza Plains, I believe. The Mooki.

4033. Do you think that some of the Macdonald waters could be diverted into that course? They could be carried across by the low range I am speaking of. I think some shafts should be sunk at the underground supply in the limestone ranges. The water gets into lower strata from these ranges and empties itself into the sea at Newcastle. I think the water goes both easterly and westerly. Diversion from the Macdonald. Underground stream.

Mr. Joseph Chaffey called in and examined:—

Mr. J. Chaffey. 9 May, 1885.

4034. *President.*] You live on the Cockburn? Yes.
4035. You are a farmer? Yes.
4036. Can you give us any information about the head of that river? It is rocky country—what I should call rotten rocks.
The Cockburn. 4037. Are there large basins and holes? In several places the hills come right into the river.
Storage. 4038. Are there any places where, by damming the river, water could be stored? That could be done all up the Cockburn. There is always water running at Moonbi, and that comes from the heads of the river.
Wells. 4039. Are there wells in the course of the river? There are four wells above Moonbi, at from 16 to 20 feet, sunk through alluvial and gravel.
4040. How far above Tamworth does the Cockburn join the Peel River? At Tamworth.
4041. Do you think that if water were stored in the vicinity of those rivers it would command the whole of the valley? I believe that water could be turned from the Cockburn to supply Tamworth.
Alienated land 4042. Is the country sold in that district? Yes, except in the case of the water reserve. It is an agricultural district.
Value. 4043. What is the land worth? About £20 an acre.
4044. If it were irrigated what would it be worth? Three times as much.
4045. Do you think that land there would be as valuable as in the vicinity of Tamworth? Almost the same.
Muddy water in floods. 4046. In flood-time is the water which comes down the Cockburn clear, or is it full of silt? It is a little muddy for a day or two.
Silt deposit. 4047. Is there any place where the silt deposit forms an obstruction? The river brings down a lot of loose gravel; it is not mud at the top—it is all gravel country with clean ridges like the hills at Tamworth.
4048. Have you a large farm up there? Not at present; all that I have is 80 acres.
Water-rates. 4049. If water were stored at the head of the river and brought down to irrigate these flats, would people be prepared to pay rates for the water? I believe that all of them would do that to have the water on the surface.
Crops in drought. 4050. The country then is subject to droughts? We have grown nothing but wheat during the last few years—we could not even grow a pumpkin last year. You can get a good crop of wheat, because it is off before the dry weather fully sets in.
Wells. 4051. In these wells of which you have spoken does the water not come to the surface? No, it keeps to the level of the river.
Banks. 4052. The banks you spoke of as coming down to the river are composed of rock I suppose? It is all rock after you leave the Moonbi Railway Station.
4053. Are there any swamp flats up near the head? Not that I am acquainted with.
Dam. 4054. Where could a dam be placed? Just above the cultivation.
4055. How broad would the sheet of water be? There is a great fall; the dam would have to be very high to keep back any very large quantity of water.
Flats. 4056. Where else is it comparatively flat about there? Somewhere about the Old Head Station. There is a broad valley taking in 30 or 40 acres.
River bed. 4057. Would you get larger flats nearer Tamworth? Yes, but the land is cultivated. If you dammed the river there you would have to stop the traffic. The river is gravelly except at a point just above the Eight-mile Bridge, where there is a rocky formation—steep hills on one side and a large flat above.
4058. How broad? Three-quarters of a mile.
Current. 4059. Does the river run rapidly there? No, the water would be thrown back a great distance.
4060. What becomes of the water running up there—does it come to Tamworth? No, it goes underneath; it goes behind the hills on the other side of Tamworth.
Subterranean current. 4061. Do you think that where water is coming down off the granite it will continue along the surface of the granite to a lower depth? I think so. As the crow flies it is not more than 4 miles from here to the granite country. There are indications that the water does go to a lower depth.
Cultivation. 4062. What extent of these flats is cultivated? It extends 16 miles from Tamworth. At one place it is about three-quarters of a mile wide, and the hills come close down on the other side. On the average there is about a quarter of a mile on each side.
Crops. 4063. What is the most profitable crop you grow? You cannot depend on anything but wheat.
4064. What would be more profitable? You might grow plenty of hay, but there is no demand for it.
4065. Will lucerne grow? Yes, but there is no demand for it.
4066. But is there no demand for it when there is a heavy drought? Last year cleared out a great deal, but I know of one place in which more than a hundred tons are stored—the owner cannot get rid of it.
4067. If you had a constant supply of water along the line of cultivation I suppose you could grow pumpkins, turnips, and other crops of that kind? Yes, we might grow maize, but there was not a crop of maize last year. I have known it to give a hundred bushels to the acre in good seasons.
Benefit from storage. 4068. Then if there were a system of storage at the head of the valley you would benefit very largely by it? Yes.
Water-rate. 4069. And you would be willing to pay for the advantage of a constant supply? Yes, I believe that all would do so.
Wells. 4070. You are a well-sinker? Yes, I have had some experience in the sinking of wells; I have sunk a good many in the sandy country, in the county of Baradine.
Soil. 4071. What soil did you go through? It is sandstone country; you can get water anywhere in the beds of the creeks—all that you have to do is to sink a well in the creek and log it up.
Sources. 4072. Where does the water come from? It falls in sandy country, sinks underneath, and forms a reservoir.
4073. Is it drift sand down to the sandstone formation? Yes.
4074. You are decidedly of opinion that the water is local, and that it does not come from any great distance? Yes.
Quantity. 4075. Do you get a large quantity of water in those wells? Yes, you cannot empty them.
Quality. 4076. Is it good water? Some of it cannot be used for domestic purposes.
Area of country 4077. What is the area of this kind of country? It is tremendous. It commences at the other side of Garrawilla, and goes in one direction towards Pilliga; I think it goes right across to Mudgee.
4078. It is more than 100 miles across then? Yes. Baradine would run short of water but for the wells which are sunk in the creeks. I have seen wild horses and native dogs get water by scratching in the creeks. You can also obtain large lobsters by digging in the sand. I heard of one hole almost
Fish in sand. filled with sand out of which some large fish were taken. That was in the Cooma waterhole. 4079.

4079. The only way of utilizing this water is by sinking wells and lifting it? Yes. In some places dams can be made, but it is of no use to make dams on the creeks. At Cooper's station there is a fine dam in a gully. Mr. J. Chaffey. 9 May, 1885.
4080. On the plains what sort of soil do you sink through? At Bando they sink through gravel.
4081. Does that come from the river? I think so.
4082. At New Bando there is a well that overflows—where do you think that water comes from? I think it must come out of the sandy country.
4083. The sandy country is higher, then? Yes. It acts upon the plains something like the mountains on other parts of the country.
4084. *Mr. Murray.*] Then in the Baradine country you think that small wells would suit the purpose of water conservation as well as any other system? Yes. If a man has money and industry in that country he need not be short of water. Small wells.
4085. And there is no extensive system of conservation which would suit the country so well? No, except in the black-soil country—there you could dam up the water. I recollect seeing a large overshot dam on the Mooki; it dams the water back for a distance of 4 miles, and I am told that it is never dry. Overshot dam on the Mooki.
4086. Did you ever sink through sandstone in that country? I went through about 20 feet, but we ran short of tools, and as there was no blacksmith's shop near we had to stop.
4087. On which side of the Cockburn is the wheat cultivation? On the south side.
4088. Any system of diverting water for irrigation purposes would have to go on the south side? The north side is not so valuable. I have made a dam at an expense of £30, and I have never known it to be dry.

Mr. Thomas Martin Hole examined:—

4089. *President.*] Where do you reside? Woolomin, on Duncan's Creek, Peel River. Mr. T. M. Hole. 9 May, 1885.
4090. What is the nature of the country there? There are so many different kinds of rock that I could hardly describe it.
4091. Is it hilly country? Yes.
4092. Is it flat about the river? Yes, there are large flats. Duncan's Creek Flats.
4093. Of what width? They vary from 200 to 300 yards from the river back to the hills on each side; they are in some places three-quarters of a mile wide.
4094. Do you know of any points where the hills come down to the river and where dams could be made? Not on the river.
4095. In Duncan's Creek? At the head of the creek there is a large table-land. I have no doubt that a good area suitable for the storage of water could be found; if it could be stopped it would be found that the water fell in a rapid stream down to it—there would be a large catchment. Storage.
4096. What length would the dam have to be? It would be very narrow indeed—not more than 50 or 60 yards wide. Dam.
4097. How far would that throw the water back? In some places it might widen out to half a mile; it would depend on the height of the dam.
4098. Say a 20-feet dam? That would not throw it back very far.
4099. Is it steep? Very steep. I may mention that a very singular thing takes place in this creek: the creek flows and then gradually sinks underneath in dry seasons. At the full of the moon the water appears to be drawn by it—every day it rises and falls again; if it rises at 7 o'clock to-night it rises at 8 o'clock to-morrow night. Tides of the stream in Duncan's Creek.
4100. To what extent does it rise? Sometimes it is drawn half a mile further down the creek than the spot where it ordinarily loses itself.
4101. Where does that water come out again? It comes out again I think in the Peel River.
4102. Do you know where? No; I have seen the creek in strong flood; the water goes down into the bed.
4103. Does it lose itself in sand? No, it is gravelly; I sank about 30 feet down, and I met with water-worn boulders all the way; the water gets underneath into another stratum I think; this stream when running is like a tide; when it gets more power the stream increases in strength.
4104. Has any gauge been established to ascertain the rise and fall of Duncan's Creek at the full of the moon? No observations have been made; I have watched it myself; I have marked it and have followed it down, but I have kept no systematic record.

Mr. Michael Burke examined:—

4105. *President.*] Where do you reside? Tamworth. Mr. M. Burke. 9 May, 1885.
4106. Have you been here many years? Over forty.
4107. Do you know the district? Pretty well.
4108. I believe you know something in connection with Eight-mile Creek? I do.
4109. Is that 8 miles from Tamworth? Yes. Eight-mile Creek.
4110. What length is it? It runs into the Cockburn; it is 4½ miles long. Length.
4111. What basin will that give you? 2 miles across, by about 3 miles in length. Basin.
4112. How close do the hills come together? There is not room for a cart to get between the creek and the base of the hills. Gap.
4113. Would the dam extend far on the crest? I do not think so; the mountains come very close together. Dam.
4114. How far back would a dam 100 feet high throw the water? I think that it would cover the whole of the valley behind.
4115. It would command the whole of this valley, including Tamworth? Yes.
4116. Would it store sufficient water to be used for settlement in the valley? Yes. Storage capacity.
4117. Is the catch very large? Yes, there is a good watershed all round; it forms a complete circle. There is another place at Moore Creek; both places would conserve water, because the bed rock is visible for a considerable distance all up the creeks. Catchment area. Moore Creek.
4118. Moore Creek is down the river? Near Attunga.
4119. Has it a large catchment? Yes.

Mr. M. Burke. 9 May, 1885.

4120. Is there a narrow point for a dam? It runs narrow for about three-quarters of a mile beyond the narrowest point, and beyond that it opens out into a nice flat.

4121. What is the width? The widest place is about a mile; it is about 5 or 6 miles long; it is comparatively level for a considerable distance.

4122. Would water stored there command the valley of the Peel River further down? Yes. I was astonished to hear that Mr. Rogers did not mention this particular spot. These are the principal places with which I am acquainted in the neighbourhood, but I should like to draw the attention of the Commission to a peculiar well about 20 miles from here, on the Manilla Road, at a place called Dead Horse Gully. A shaft was sunk 120 feet and there was no indication of water, although about 80 yards away permanent water is found at from 8 to 11 feet.

Dead Horse Gully.

4123. Any quantity of water? Yes.

Flow of water.

4124. Does it seem to have a flow in any direction? From the hills. They sank the shaft in a hollow, where they thought the water would be found, but they found none; they then sank a tank on the ridge, and that is the place in which water is now found.

Quality.

4125. Is it good water? Splendid.

4126. I believe that there is a stratum coming down along this ridge which contains plenty of water? Yes.

Bores.

4127. Were bores never put down? Not that I know of.

4128. You conclude that the subterranean water flows from the hills? Yes.

4129. And you know of no place where it appears on the surface? None at all.

Cave.

4130. *Mr. Murray.*] Do you know of a cave in the hills behind the town where there is underground water? I have heard of such a cave, but it is a very difficult matter to get to it. The interstices of the rock are exceedingly narrow, and I have heard people say it is extremely difficult to ascertain whether there is water there. I should think that it is a little more than a mile from Tamworth.

Mr. Robert Ralph Lawrenceson examined:—

Mr. R. R. Lawrenceson. 9 May, 1885.

4131. *President.*] Where do you reside? Tamworth.

4132. How long have you resided here? Eleven or twelve weeks.

4133. What is your calling? I am road superintendent; I have charge of the iron bridges at Manilla, Bingera, Bingera Creek, Boggabri, and Gunnedah.

4134. What is the nature of the evidence which you wish to give? I know the Namoi all the way down.

4135. What is the nature of the country from Boggabri to Manilla? It is very rough.

Storage at Keepit.

4136. Have you noticed any spots on the Namoi where large quantities of water might be conserved? I am certain that many such places might be found; there is one, for instance, in the neighbourhood of Keepit.

Flats.

4137. Are the flats of any extent? Not just there.

4138. Are they so higher up? Yes, about Carroll and Gunnedah.

Dams.

4139. Do the ridges come near to the river at any point in such a way as to afford facilities for the construction of dams? I have noticed that they do in several places.

4140. And at those places could the water be thrown back any great distance? At Carroll you could do a great deal in that way. The plain runs right out to Breeza.

4141. Is there any ridge above that which would permit of the storage of water above? I do not think so; it is flat on one side, and you would be unable to get any place where you could construct a short dam.

MONDAY, 11 *MAY*, 1885.

At Gunnedah.

Present:—

Mr. FRANKLIN, C.E.,	Mr. MURRAY, M.P.,
Mr. LYNE, M.P.,	Mr. M'MORDIE, B.E., C.E.

W. J. LYNE, Esq., M.P., PRESIDENT, IN THE CHAIR.

Mr. Thomas Polk Wills-Allen called in and examined:—

Mr. T. P. Wills-Allen. 11 May, 1885.

4142. *President.*] What is the name of your station? Gunnible.

4143. How far is it from Gunnedah? 5 miles—that is, the head station.

4144. On what river? The station is on the Namoi.

4145. Have you lived in this district many years? Nearly thirty.

4146. Have you been following pastoral pursuits most of that time? The whole time.

4147. You have had an experience of the country in its variety of seasons? I have.

Irrigation.

4148. And you have lately made some experiments with irrigation? I have.

Engine.

4149. Will you kindly give in detail your experiments and their result? I have a stationary engine, 30-horse power, which I erected in 1876 for the purpose of sheep-washing, keeping in mind its probable value for raising water for irrigation. From 1876 to 1884 the water pumped up, after it had served the purpose of sheep-washing, was allowed to flow away over the land. The water, although the pumping continued from seven to ten weeks, in some seasons never got beyond a point about half a mile from the pump.

4150. That was because you had no channels in which to convey it? Because it was allowed to flow over the land as it pleased. In 1884, after the water had served the purpose of sheep-washing, I applied it to the irrigation of crops which I had laid down. The result was the production of a crop of wheat for hay exceeding 3 tons per acre, or about 80 tons of hay from 25 acres of land.

Results.

4151. And what other crops? I also irrigated a crop of lucerne. In consequence of irrigation, we have had since the 1st November about five cuttings, averaging about 1 ton per acre per cutting. After the crop of wheat was removed, the land was planted with corn; planting finished in January. The result has been a crop estimated at fully 40 bushels per acre, and a luxuriant growth of pumpkins throughout the corn.

4152.

Mr. T. P. Wills-Allen. 11 May, 1885.

4152. When you commenced to irrigate several years ago, were you sanguine from the results then obtained that it would be a success? It was only later experiments which induced my confidence in it; I was not sanguine, because I had not tried it.

4153. After you had tried it, without making drains to convey water a certain distance, were you sanguine? I was not at all sanguine, except on the principle that water would produce vegetation if rightly distributed.

4154. How long is it since you felt that it would be a success in the end? My success has been assured within the past six months—I have now the fullest confidence. I have been practically irrigating for only six or eight months, and the result has been so thoroughly satisfactory that I have not the smallest doubt as to the issue.

Quality of land.

4155. Is the land you are irrigating more than average land? It is only average—indeed it is rather below the average in point of richness.

Choice of land.

4156. Why did you select that spot? Because it was suitable for a washing-place, and there was an abundant supply of water.

4157. And it was not selected on account of the peculiar richness of the soil? No.

Results without irrigation.

4158. What result do you suppose you would have obtained from that land without irrigation? In such a season as we have just passed through I am sure it would not have returned the seed.

4159. During the time these crops have been growing the seasons have been bad? Yes—exceptionally dry and hot.

Expense.

4160. Have you any idea of the expense to which you have gone in irrigating this land? There has not been £50 expended except in clearing it and in preparing it for irrigation—very little indeed.

Extension.

4161. Are you preparing to extend the area of your irrigated land? A professional gentleman recently took the levels of about 400 acres, with a view to getting the land cleared and laid down under crops. I am so satisfied with the result of irrigation that I have no hesitation in extending my operations; my only fear is whether I am acting within my rights in drawing such large quantities of water from the river.

Effect of pumping.

4162. I was going to ask you the effects of pumping? When there is a fair supply of water in the river it appears to have little or no effect—no perceptible effect.

4163. But at other times? At other times it does not appear to have more than I have noticed in hot seasons from evaporation; the river lowers day by day in hot weather, and during the drawing of water from it there was a perceptible lowering, which perhaps could be accounted for only by the pumping; but there appears to be a general impression that the river would rise to its previous level after being allowed to rest for a few days.

4164. Do you think that if a number of persons residing on the banks were to adopt a system on the large scale you recommend, it would perceptibly diminish the river supply? In a fair season I do not think it would; I think that much of the water drawn from the river for irrigation purposes would find its way back into the stream by percolation.

Value of land.

4165. What would you suppose to be the difference in value of land of the description you have irrigated before and after irrigation? I should think the land would be much increased in value with an available supply of water for irrigation.

4166. What is your idea of the difference? It is a difficult matter to arrive at any value; putting it in another way, however, I am sure that the results from the land would be more than quadrupled.

Crops.

4167. Have any persons in your neighbourhood during this dry season attempted to grow hay or corn during the time you have been growing your crops? Hay and lucerne have been attempted, but I think in almost every instance the crops throughout the district have been failures; the wheat crops have been fair, not immediately round Gunnedah but in the district; attempts at growing lucerne, however, have been an utter failure; in dry seasons like the present, or indeed in average seasons, the growth of maize, when attempted, has always been a failure.

4168. Have you a good knowledge of the country up the river from this point? I have.

Natural basins.

4169. Do you know of any natural basins near the river in which large quantities of water could be stored? Taking the course of the Namoi for 50 miles eastward, the most suitable point I know of is the one which I have heard referred to as having been noticed by the Commission.

4170. Where is that? At a point about 6 or 7 miles above the junction of the Peel, where the Nandewar Range hits the Namoi on its northern bank.

4171. Is that the point at which you understand the Commission have had levels taken? It is rumoured that the Commission have made inquiry about that point.

4172. Do you know of any other points at all similar? I do not know of any to compare with the large results which might be expected from a dam across that point of the river. It is a natural basin, which would extend probably from 10 to 15 miles upward, and which would have a breadth of from 1 to 5 miles.

4173. To what width would the banks require to be dammed? I have no idea; I have not examined the locality. There is a mountain range which comes in almost precipitously to the river on the southern bank, corresponding with that from the main Nandewar Range, hitting the river on the northern side. I do not think they are far apart—less than half a mile.

4174. Do you know of any other points? I know of none to compare with that.

Tulcumba Creek.

4175. None which can be utilized, although not of such magnitude? There is a point on the northern side of the Namoi, the valley of the Tulcumba Creek, where a large storage of water might be obtained, but its watershed would be out of all proportion and unequal to the storage. The watershed is small compared with the storage which might be obtained there.

Cost of resuming land.

4176. Could you give us any idea of the cost of resuming the areas of alienated land which would be covered by water in the event of these several dams being constructed? I could not; it would be a question of the individual value set upon property.

Crown lands.

4177. Is much of it Crown Lands? I think it has been alienated along the river flats.

4178. That is the land which would be covered with water? To some extent; a great deal of Crown Lands would be also covered by water.

Value.

4179. What is your opinion of the value of that land? Its present market value, in the case of conditional purchases, would not exceed £2 per acre.

4180. Do you mean £2 an acre in addition to the balances? Yes; roughly from £2 to £3 per acre.

4181. Do you know of any points in the district, not on this river, where water could be conserved in large quantities? No, I do not.

Mr. T. P. Wills-Allen. 11 May, 1885.

4182. Do you think that the principal works would have to be in the basin of the river? I think so. I have an intimate knowledge of most of the district, and I can think of no place which in its results can compare with the place which I believe the Commission have already under consideration.

System of water conservation.

4183. In adopting a system of water conservation, how would you expect it to be applied in the first instance where there are large holdings—would you expect irrigation to be carried out on a small scale, or would you expect the water to be diverted on to the back plains, and utilized for filling tanks and dams? I think that where a sufficient supply of water is available for irrigation, there is not the smallest doubt that it would be used for that purpose, and also for filling tanks.

4184. At once? As soon as practicable.

4185. Do you think that where there is not a large population, the water would be used to grow produce for market only, or to grow produce upon which to feed stock in dry seasons? I think the growers would use it for producing that which appeared to them to be the most profitable, whether for the purposes of market or not; in most cases I think it would be grown for market purposes, because most persons would be interested in realizing as soon as possible after the growth of the crop. Station-holders might grow for the purpose of storing; there would probably be a combination of the two purposes.

Growth of hay.

4186. Do you think that station-holders would be likely to utilize the water to a large extent for the growth of hay, which would be stored for dry seasons? I think that where the supply of water was abundant and could be obtained at a moderate cost, they most assuredly would.

Quality of land.

4187. As a rule, is the land throughout the district sufficiently good for agricultural purposes? I think that large quantities of it are suitable for agriculture.

Quantities for distribution.

4188. Could water be distributed through it? Yes; from a supply at the point I have already indicated.

4189. Do you think that any large quantities of water could be impounded in the river by throwing weirs across it at suitable points, and filling up the channel? Not without the aid of large dams, from which weirs could be supplied; the water-holding capacity of the river is very small; the banks give an

Height of banks.

average height of about 20 feet, and it would probably be about 2 chains wide. The water-holding capacity would therefore be very limited, even if the weirs were at distances of 20 or 30 miles throughout the course.

Diversion from reservoirs.

4190. Supposing a large quantity of water were stored in natural basins at the heads, could it be brought down in the main channel and diverted through the plains as required? That would depend upon the position in which it was required. In some cases it would be required 10 or 15 miles back from the river. In such cases as that the water might be brought direct to the point at which it is required. As far as the banks of the river are concerned, they would be best supplied from the river itself.

4191. By pumping? Pumping would be expensive. Weirs and large reservoirs might be made the means of overflow at particular points. Weirs would be valuable not only in pouring water over the banks, but also for preventing water from running to waste unnecessarily.

Water-rate.

4192. If the persons using the water benefited, do you think they would object to pay a rate sufficient to cover the interest on the money borrowed for the works? It would become entirely a matter of the cost of the water to them. If very costly works were engaged in, and the interest involved the payment of a heavy rate, they would have to consider whether the results would justify it; but where the supply of water would not be too costly, I think they would pay a rate without hesitation. Suppose I put an imaginary sum as to the value of the water per acre. I should say that where land could be irrigated at a cost of from 5s. to 10s. per acre the return would well repay the cost.

4193. And the persons interested would be willing to pay it? They ought to be. The results in my own case prove conclusively that they ought to pay it. The price I have named would be for each separate watering. I mean by irrigation not only watering the land, but inundating it—covering its surface.

Trusts.

4194. Do you think we should have to resort to a system of Trusts to carry out these great works? I have no experience in anything of the kind. I could not say. Doubtless it would be a more methodical way of dealing with the matter.

Silt.

4195. Is there much silt in the river at the time of flood? No; my experience, as regards grass land, is that the deposit is not great; there is a deposit; the current is by no means rapid—when it reaches the level country it loses its force to a great extent.

4196. Do you think that in these natural basins, if a large quantity of water were conserved, there would be much silt to continuously fill them up at time of flood? I do not think there would be a great deal of silt; the source from which these waters are derived is unfavourable to the accumulation of silt. The Namoi, in most of its courses down to the point at which it is proposed to construct this large reservoir, runs through and between rocky hills; the bed, for a great deal of the distance, consists of rocks and boulders; when it emerges from the mountain ranges at Manilla the bed is shingle, and the banks are solid for the rest of the distance; I do not think, therefore, that much silt would be carried down, although timber and débris no doubt would if not burnt off along the banks.

Wells.

Underground supply.

4197. Have you any knowledge of an underground supply through sinking wells in this district near the river? I have sunk a good many wells. The underground supply varies very much. On my own run I have found an abundant supply for watering stock in every instance. I have about ten wells sunk on Gunnible.

4198. Are they at any distance from the river? They vary from 3 to 7 miles.

Strata.

4199. Through what did you pass? Clay.

Depth.

4200. All the way down? All the way until we reached the gravel bed; then we found the water. I have found it at from 30 to 130 feet.

Current.

4201. Have you noticed any current in these wells? Never.

Supply.

4202. Then you think you obtain simply soakage water? Some of the wells give a greater volume than others; some wells, those with gravelly and fine sand bottom, contain only about 4 feet of water, and are inexhaustible by the means I employ, viz., whims and 50-gallon buckets, raising about 10,000 gallons daily; others, with a kind of concrete or cemented clay and boulder bottom, have 40 feet of water in them, and are more easily emptied. I have one well in which there are not more than 4 feet of water, and all my efforts to lower it, with whim power, are unavailing.

Current.

4203. Can you detect no current in that well? There is an inflow; we cannot tell whether there is a current, but the inflow is rapid.

Source.

4204. Have you any idea as to where the water comes from? It would appear to come from the Namoi.

4205. Did you get it about the river level? No, we got it rather below the river level.

4206. Is it at all artesian? I do not think so.

Mr. T. P. Wills-Allen. 11 May, 1885.

4207. It does not rise? It rises to a certain height—to the level at which we tap it, but it does not rise beyond that.

4208. It is at that point below the river? Yes. In three or four cases the point at which I have sunk wells has been certainly not more than 30 feet higher than the river, and the shallowest of the wells is 40 feet.

4209. Do you suppose it to be river water if it is found below the level of the river and does not rise up to the level? My only reason for supposing it to be so is that it is unlike the water got at a great distance from the river. I have three wells sunk in the same line; the water is all more or less impregnated with lime—it appears to come from a limestone source. I have no doubt in my mind that they come from the Tulcumba Valley. I sank a well many years ago at the head of the Tulcumba Creek, and the water which I then obtained corresponds exactly with the water which I obtain in the three wells which I have named. There is a low dividing ridge, almost imperceptible, which appears to divide the Namoi waters from the waters of Tulcumba Creek. On the northern side of that low ridge all the water in the wells appears to correspond exactly with the water on the Tulcumba Creek obtained from the wells. On the southern side of the same ridge all the water appears to partake of the character of the Namoi water. In the one case the depth is from 80 to 130 feet—that is on the northern side. On the southern side the depth is about 40 feet. The Tulcumba Creek loses itself when it reaches the plains, except in flood-time, and then it finds its way down and joins the Namoi about 10 miles below Gunnedah.

Storage at the Big Gap.

4210. Are there no points higher up where large quantities of water could be stored? There is a point at the boundary of Tulcumba and Gunnible Runs, at a place called the Big Gap, very suitable for storing a large quantity of water, but the watershed would not be equal to a very large supply.

4211. Have you had experience of wells in any part of this country? No.

Bando well.

4212. You know of no artesian wells? None; I have heard of a well at Bando which is supposed to be artesian.

4213. Where is Bando? In the county of Pottinger.

Underlay of water.

4214. Has it struck you that where water gets out of the river by soakage to a large extent, that there may be a large flow in the higher parts which is lost lower down? I think there is an underlay of water throughout the whole of the country.

4215. Do you think it comes from the river to a great extent, and lessens the volume of water? I decidedly think so.

4216. I understand you have another property, near Walgett—what is the name of it? I have a property near Goran Creek called Killala.

Depression at Killala. Size.

4217. There is a depression there? Yes.

4218. What size is it? I cannot speak accurately about it. From what I have seen, I should say that when it is full it must cover an area of several thousand acres.

Source of supply

4219. Where is the drainage from? It receives its supply from the Bando country.

Nature of soil.

4220. What kind of country is that? Black-soil plains; I should say that as a storage for water it would be perfectly useless; it would be a large sheet of shallow water, easily overflowing on to the plains below. I have only heard of its being filled once or twice, and then, as I have said, it is very shallow. The place is altogether unsuitable for the storage of water.

Opening in the Nandewar Range.

4221. *Mr. Franklin.*] Are you aware of any opening in the range between this and the junction of the Namoi and Manilla? That is the range I have referred to, Nandewar Range, abutting on the Namoi on the northern side; there is another high range abutting on to the river on the south side.

4222. Below the junction of the Manilla? Yes, 15 or 20 miles below.

4223. How far above the junction of the Peel? 6 or 8 miles by the river.

Conveyance of water to the plains.

4224. If it were possible to raise the water to a level above the banks at that situation, it might be conveyed on either side of the river through the plains? The Peel River junction is below—you would have to cross that river; there are also low spurs of the mountains abutting on the river at various points, but it would no doubt be possible to carry out the work you indicate. It might be a little expensive to do so, but there is nothing to occasion any great difficulty.

Storage below junction of the Peel.

4225. Are you aware of any site below the junction of the Peel where, without considering the storage of a large quantity of back water, the ordinary river water might be raised to bring it on to the plains without obstruction? I do not know of any.

4226. None for a weir to embrace the discharge of all the rivers? I do not know of any. It must be borne in mind that there may be places—I do not remember them just now.

Distance of distribution.

4227. Supposing it were possible to convey impounded water across the Peel on this side, to what extent would you be able to lead the distribution towards the plain country? Many miles on the Carroll and Breeza Plains.

4228. Where is the obstruction to your continuing it on towards Coonabarabran? There are dividing ranges. There is a large area on the north side of the river which might be commanded, on the Burburgate, Gunnible, and Carroll North runs country.

4229. What do you calculate, approximately, would be the length of the main channel for that supply through its course? It might be carried indefinitely on to Narrabri and below; it would have no limit—it might go as far as the supply would reach; it might be carried to the western country if the water supply were equal to it.

4230. But you say that it would be interrupted by a ridge? That is in the Coonabarabran direction. Routes might be found by going away from the course of the Namoi. It makes a deep bend from a point near Carroll, and a direct channel from that point to a point near Boggabri would water a great deal of now waterless country.

Direction.

4231. Would you trend westward from that point. No, rather to the north of west.

4232. We are thinking of the south side of the river? That would not be available below Gunnedah, as spurs of ranges come in at various points. There is one at Gunnedah.

4233. That would be the terminal point of the main channel from that source? I think it would. It might be diverted, but its diversion would not be possible more than 2 or 3 miles from the river for some distance.

4234. Do you think it would be well to consider the obstruction of which you have spoken, with a view to see whether the channel could not be extended further away to the westward? It might be worth consideration. The country opens out to the westward at Cox's Creek. I should imagine that all the frontages on the southern side might be better reached by supplies from the river itself than from the main channel on that side. There are numerous abutments on the southern side.

Mr. T. P. Wills-Allen. 11 May, 1885.

4235. Do you know the nature of the Bendemeer? I do.

4236. I believe there is a constant flow in that river, is there not? I think it might be said to be almost constant. I have seen it in holes.

Storage in the Bendemeer.

4237. You do not know whether if water were impounded there it would serve the same purpose on the northern side as the course which I am now proposing? You would have greater difficulty in conveying water if it were impounded above Manilla, from that point down, from the hilly nature of the country, than if you started from a point nearer this way.

4238. At this spot, of which we have made some examination, would it be possible to supply water on the northern side? Quite possible; whereas, if an embankment were made at Manilla, or higher up, all the difficulties of carrying water through rugged country would have to be overcome. The proposed site of the embankment is so near the level country that there could be little difficulty in carrying the water from the embankment further on.

Area of country benefited.

4239. You would go right through the Nandowar into the county of Jamison? I am inclined to think that from 100,000 to 150,000 acres of level country would be covered within a radius of 40 miles of the embankment. Taking Carroll on the south, you would have 30,000 acres; Pullamin, 40,000 acres; Gunnible, 30,000 acres; Burburgate, 50,000 acres. The two last are on the north side.

4240. Of the aggregate quantity the larger portion would be on the southern side? North and south would be in about equal proportions.

4241. What is the extent of the channel line towards Narrabri? It would open out in the Jamison county. It might be made right through Nandewar to Narrabri. It might also go through the county of Denman to Mille, and then away towards the Barwon, embracing millions of acres of extremely rich country which is comparatively waterless except by means of tanks and dams. You would pass through country in which there are very few natural facilities for storing water.

4242. *Mr. Murray.*] It would intercept Galathera Plains? Yes.

Settlement.

4243. There is very little agricultural settlement at present along that line? Very little.

Sold land.

4244. *President.*] Is much of the land sold in that direction? A great deal still remains unsold.

Irrigation.

4245. *Mr. Franklin.*] In raising the water on to your land, do you convey it by reduced grade to bring it above the surface and irrigate by gravitation? It is conveyed through channels.

Raising of water.

4246. But are they raised above the surface? They are excavated below.

4247. To irrigate you must get an outflow on the surface at the length of the cut—you can get an outflow immediately after the water has discharged? We do so by blocking the channel and causing an overflow.

4248. Has any other attempt been made to irrigate in a similar manner? The attempt has not been made, but works are in course of construction at Burburgate.

4249. Is the water you draw for irrigation the natural water of the river? Yes.

Reach of water.

4250. What is the extent in length and width of the reach of the river from which you draw? It is a large and continuous reach of water, about 2 miles long, and of an average width of about 2 chains.

Pump.

4251. What is the power of your pump? It is 30-horse power.

Discharge.

4252. What is the discharge? It is a 13-inch centrifugal pump. The discharge is stated to me by the firm from whom I purchased it at 2,700 gallons per minute.

4253. Can you tell me the greatest length of time for which you have pumped continuously at that power and with that discharge? We have pumped for a whole week.

4254. Day and night? Yes.

4255. Without cessation? Yes.

Diminution of water in the river.

4256. Did you notice any diminution of water in this long reach after that pumping? With a flow of water in the river the diminution is nothing, but when the stream has ceased the diminution is very evident.

4257. Would you say an inch? I say it lowered quite at the rate of an inch per day of twenty-four hours' continuous pumping.

Flats for irrigation.

4258. *Mr. Murray.*] Do you think that there are many flats in the district as favourably situated for irrigation as that upon which you have experimented? I think so.

Loss of stock.

4259. Are you aware that large quantities of stock have been lost through the want of grass during the last seven years? I am.

4260. Do you think that if your system of irrigation had been adopted, or if some other system of irrigation had been in existence, all that loss would have been averted? I feel sure that a large amount of it might have been averted.

4261. Can you roughly estimate the quantity and value of the stock lost in these parts of this district for which such a supply of water as I have indicated would be available? In 1877 I feel sure that 50 per cent. of the stock in the Liverpool Plains district died. The later drought has not been so severe; but I am sure, from a careful analysis, that what I say with reference to the drought of 1877 is correct.

Storage of feed.

4262. How many stock would the quantity of hay which you have stored at the present time preserve in case of drought for three months? I have only about 120 tons stored, and that would not go far. I hope to preserve 2,000 tons; then I shall be beyond the danger of drought.

Cost of machinery.

4263. I do not think we ascertained the cost of your machinery? The machinery and appliances for sheep-washing cost £2,500.

4264. You apply the machinery to sheep-washing and sawing as well as to irrigation? Yes.

Water rate.

4265. Would you be content to pay from 5s. to 10s. per acre for water supplied? I should gladly pay 5s. per acre for each irrigation on cultivated lands.

Supply in the Namoi and the Peel.

4266. Are you aware that there is sometimes less water in the Namoi below the junction with the Peel than in the Peel itself? I do not think that is the case. I know both the Peel and the Namoi. I had a run with a frontage to the Peel. I think that the Namoi holds the larger body of water, and has a more reliable watershed than that of the Peel.

Practicability of distribution.

4267. After your long experience you think then that it would be quite practicable to raise water from the river and distribute it over large districts? Without going into the matter very accurately, the work appears to me to be eminently practicable.

Water rate.

4268. And you think that pastoral tenants, as well as free-selectors, would pay a fair rate to cover the interest on the money expended? I think it is peculiarly a measure adapted to the requirements of the agriculturists much more so than to those of the pastoralists.

Mr. Irving Winter called in and examined :—

Mr. I. Winter. 11 May, 1885.

4269. *President.*] You own Tulcumba station? Yes.
4270. Have you resided many years in this district? Eleven years next October.
4271. You have a thorough knowledge of the whole district? Of my own place.
Natural basin.
4272. Is there a natural basin on some part of your run which would be suitable for impounding a large quantity of water? Yes; but I question if you could get the water out after you had impounded it.
4273. Do you think that it is practicable to impound a large quantity of water there at a reasonable expense? Yes, I think you could.
Distances.
4274. How far is it from the plain country upon which the water would be utilized? It is about 17 or 18 miles from this place in a straight line.
4275. But how far from the plain country upon which the water would be most utilized? A mile or two; say 4 miles.
Difficulties.
4276. Do you think that the difficulty in connection with bringing the water out of the reservoir would be very great? I think so.
4277. Why? Because there is a large ridge there.
4278. What would be the great difficulty? To get through the ridge.
4279. But if you followed close to the river could not that difficulty be overcome? There is another obstacle.
4280. Suppose you ran above the bed of the river, but through the same gap? There is a succession of ridges, but one is larger than the rest.
4281. Would it not be possible to run the supply close to the watercourse? I think that it is hemmed in too much. Higher up above the ridge you could go in another direction. There is a point just above Malliwindi where a large storage basin exists; it is at the junction of Spring Creek and the Namoi.
Storage basin.
4282. Does it seem as extensive a basin as the other? No, but you could get the water out of it better than out of the other one.
Catchment.
4283. Is there a good catchment? Yes.
Direction.
4284. If the water were impounded there, which direction would you take in which to utilize it? It would come across through the ridge into Tulcumba Creek. You would require some surveys. I think that the water could be brought down to Gunda.
4285. Do you know of any other points? I do not.
Area of lake.
4286. What extent of country would the artificial lake cover of which you first spoke? 2,000 acres. The country is broken, and you cannot estimate the level.
Land.
4287. Is it Crown Land? There are a few selectors.
4288. Then some of it is alienated? A good deal of it.
4289. I suppose some of it still belongs to the Crown? A great deal of it.
Value.
4290. What is its value? It is very poor; the ridges run so close together that the flats are very small.
Quality.
4291. The land is not very rich? You could get it for about £2 per acre, including the unpaid balances.
Tulcumba Station.
4292. What is the extent of your station? About 80,000 acres.
4293. How far does it run up into the ranges? Up to the heads of the Manilla and Borah Creeks, and the county boundary line between Darling and Nandewar.
Nature of country.
4294. What is the nature of the country? Broken plains. At the head of the run the mountains are 3,100 feet above the level of the sea.
Wells.
4295. Have you sunk many wells there? A good many.
Soil.
4296. What sort of soil did you go through? Clay and rock.
4297. What sort of rock? A kind of trap; I saw in Mr. Czarlinski's room at the hotel a piece of rock similar to that through which we have passed.
4298. And you have to go through that rock to get water? Yes.
Depth.
4299. What depth are the wells? All depths; I think that the shallowest is about 30 feet; they go up to about 160 feet; the alluvial wells are deep.
Supply.
4300. What supply of water do you get? A good deal. It is impossible to pump out one well which I have, although there is not more than 2 feet of water in it.
4301. Does that come through the same kind of rock? No; hematite.
Current.
4302. Can you trace any current in that well? Of course the water runs into it.
4303. But can you trace it going from or going in any direction? Not in any direction; we do not place much dependence on it, as a direction may be seemingly altered by impervious strata.
4304. Is it flowing? Yes; it goes through the well.
Direction.
4305. In what direction does it appear to flow? I should think that it goes from north-east to about south-west. I sank another shaft about 100 yards off and only got soakage water in it. That seems to go to the river.
Source. Supply
4306. Where does the water come from? Out of the ranges, I think. It was originally struck at 20 feet, but by constant pumping we were able to get down to 30 feet. The water will keep at about 2 feet, but in the course of a month or two we shall have to sink again. We had two horses and four men working continuously from Monday morning until Friday night to fill and dig out tank, and they did not lower the water an inch, but it has lowered since.
4307. That would probably be owing to the drying up of the country at the source? Yes, the supply would be lessened in that way.
Irrigation.
4308. On any part of your run is there land which you could irrigate if the water were brought down the river? There is any amount of it.
4309. If a supply of water were available, would you adopt a system of irrigation for the use of the station? I do not know. If I thought that it would pay I should do so.
4310. If it could be demonstrated that it would pay you would? Of course.
Wells.
4311. *Mr. M'Mordie.*] With reference to the current passing through the well, there must be drainage into the river bed? A line of apple-trees denotes the line of the current. It is simply drainage from the mountain into the bed of the river. Some selectors have sunk wells in the low country, but they have not got water. It is a very narrow stream.
4312. How is that known? I had a well within 100 yards of the other well, and I got simply soakage there. There is no quantity of water below the line of the apple-trees. Half a mile above I sank a shaft 60 feet through rock, but got no water. I had another well about a mile to the north-east through about 100 feet of rock, but it has gone dry.

Mr. I. Winter. 11 May, 1885.

4313. So the wells were sunk through different kinds of strata? Yes; the deepest wells are those in the alluvial—they are from 130 to 160 feet deep.

4314. *Mr. Murray.*] Previous experience would lead you to sink in the line of the apple-trees? Yes; but the trees are no criterion, except the water be shallow.

4315. Have you had any experience further down the valley? No.

Irrigation.

4316. Have you adopted any system of irrigation about the homestead? No, with the exception of water being laid on to the garden. I put a mill on the well; it pumped the tanks full and the surplus water ran over the surface, flooding about 2 acres, but the stock would not look at the herbage which grew on it.*

4317. What was the reason? It was too rank.

4318. Would they not eat it if they could not get grass anywhere else? I have taken horses there—they have eaten a mouthful but no more. The surrounding country was absolutely bare at the time.

4319. Is there any property in the water to account for it? I think not; the stock would drink the water.

Mr. George Fawcett called in and examined:—

Mr. G. Fawcett. 11 May, 1885.

4320. *President.*] Where do you reside? At Burburgate. I have been manager of Burburgate station.

4321. For how long? Three years.

4322. Is it a large station? About 300,000 acres.

4323. Is it near the Namoi below Gunnedah? About 7 miles.

Country.

4324. What is the nature of the country generally? There is more timber than plain.

4325. Ordinary box? Yes.

4326. Flat? Flat and hilly; flat near the river.

Irrigation.

4327. While you were manager of the station did you attempt any irrigation works? None.

4328. Have they attempted any since? Yes.

Extent.

4329. To what extent have they carried them? It is only experimental at present. I believe they will cover 170 acres.

4330. Have they actually irrigated that area? They have everything ready. The only drawback is the want of water.

Preparation of land.

4331. How are they preparing the land for irrigation? They have it all ploughed and drained, and they mean to have leaders from the main drain.

Drains.

4332. Are the drains so situated as to be a little above the adjacent land? No, the drains will all be below. They will block the drains at the end when they are full; small furrows will be made from the leaders.

4333. Are the works on the slope? In some places; in others on the high land.

4334. Then the drains are actually higher than most of the lands which it is intended to irrigate? Yes.

Sections.

4335. Are they dividing the land into large sections? Yes.

4336. Very large? Not very.

4337. What sections do they propose to irrigate at one time? The 170 acres are divided into three irrigation paddocks. They have started another paddock about a mile further down, with a view if the present works are a success to continue the drains and to irrigate more.

Extent.

4338. Have you any idea as to what extent they propose to irrigate if the present works are a success? They talk of irrigating land about 2 miles from the head station.

4339. About how many acres? About 2,000.

Pumping.

4340. Do they propose to raise the water by pumping? Yes.

4341. What is the size of the pump? About 10 inches at present. They intend to get another afterwards.

Engine.

4342. Do you know the engine power? 30-horse power.

4343. Have you tried irrigation for agricultural purposes? No.

Success.

4344. From what you have seen of these works do you expect that they will be a success? I think so.

4345. Do you think that if there were an unlimited supply of water at the present time they would be carrying on their irrigation works? I am sure of it.

Water-rate.

4346. Do you think that if water were supplied, the company would be prepared to pay a reasonable sum for it? I think so.

Wells.

4347. When you managed the station had you any experience of well-sinking? Yes.

4348. Are there many wells sunk on the station? About thirty on the south side and about a dozen on the north side.

Soil.

4349. What did you sink through generally? Through clay.

4350. Have you sunk through rock? It has been done in several instances.

4351. And you obtained water? Yes.

Supply.

4352. Any supply? Yes, a good supply.

Current.

4353. Have you ever traced the water as flowing in any direction? It is generally looked upon as river water.

Bed.

4354. What did you get it in? In gravel.

4355. In a river drift? Yes.

Level.

4356. Did you get it at a higher or at a lower level from the river? Generally at about the same level as the river.

Rise.

4357. Does the water rise in the shaft? To a certain extent—about 4 feet I should say. I have known it to rise 30 feet.

Source.

4358. Where do you suppose it came from? It is not river water, because it is not as good water as we are in the habit of getting in the other well.

Quality.

4359. Is it mineral water? It is rather brackish.

Source.

4360. Have you any idea where it came from? I should not say that it was river water.

4361. What is the source? It is not from the river side.

4362. Does it come from higher ground? I should think from the hills.

Irrigation.

4363. What extent of country is there on the station which might be brought under irrigation if water were at command? I should say 40,000 or 50,000 acres.

4364.

---

* Note (*on revision*):—This answer refers to the well and tank spoken of at Question 4306.

4364. What is the principal object the Namoi Company have in irrigating so much land in the first instance? I think it is to prepare against loss in time of drought; they wish to have hay at command instead of sending down to Maitland. Mr. G. Fawcett. 11 May, 1885.

4365. They have not made these works for the purpose of grass irrigation? No, but eventually they look forward to that.

4366. Do you think the country will grow lucerne? I believe it would. Lucerne.

4367. Have you had any experience further down the river or in any other part of the district? Only about Burburgate.

4368. *Mr. Murray.*] Have you considered the question of irrigation by gravitation instead of by pumping? No, I have not. Irrigation.

4369. Why did you not consider it? Because the water was not available.

4370. Is there no suitable place for a reservoir high up the river? I do not think that idea was ever entertained; I have no doubt it could be done. Reservoir.

4371. The alienated lands there through which the race would pass would deter private individuals from undertaking the work? Yes.

4372. You think, however, that the work could be done by the Government with satisfactory results to everybody? I believe it could.

4373. And that the people would be prepared to pay a fair share towards the interest on the money expended? Yes. Water-rate.

4374. *President.*] Do you think a system of Water Trusts would be the best way to deal with the question? I think it would. Trusts.

4375. Would it be preferable to individuals carrying out their own schemes? I think so.

4376. Are the floods very extensive on the station of which you were the manager? They have been. Floods.

4377. How far do they go out from the river? On the south side I have seen them 3½ miles, and on the north side about 2 miles.

4378. Is there much current in the river? It is pretty strong. Current.

4379. Have you noticed that the ground near the bank of the river was higher than the land further back? Some of the banks would be. Banks.

4380. Did it ever strike you as being always so? No, I cannot say that it has; I have seen places where the banks have not been under water while the country 3 miles back was inundated.

4381. As a rule, supposing the water were raised in the river to a level with the banks, could it be brought on to land a considerable distance from the river by gravitation? Yes. Distribution by gravitation.

4382. This could be done either by pumping or by water being raised by means of dams across the river? Yes.

Mr. John James Smyth called in and examined:—

4383. *President.*] You are a resident of Gunnedah? Yes. Mr. J. J. Smyth. 11 May, 1885.

4384. Have you lived here long? Yes, twenty-one years.

4385. You have a good knowledge of the district? I have not travelled about it a great deal.

4386. And you know the neighbourhood of Gunnedah? The immediate neighbourhood.

4387. As a rule are the seasons variable here, or have you a run of good and bad seasons? They have all been bad during the last seven years; when I first came here we had very decent seasons—a run of wet seasons—but since then we have had a long run of dry ones. Seasons.

4388. Have you had any experience in squatting? Not the slightest; I have only supplied squatters with stores.

4389. Your experience is confined almost entirely to the town? Yes.

4390. Have you sunk many wells? I have put down two wells myself. Wells.

4391. What was the nature of the sinking? I went down about 35 feet; I came upon water so salt that I filled the well up again; I went through a kind of rotten stone principally, with layers of pipe-clay cement. Salt water.

4392. When you struck the salt water did it rise? Only about a foot. Rise.

4393. Have you formed any idea as to the cause of the saltness of the water? No; I was surprised to find it salt, because 2 chains from where I put the well down there was good water about in a line from the spot at which I sank; 2 chains further on from that there is another well with good water; that is about 40 feet deep. Good water.

4394. Have you attempted other wells? The only other experience I have had has been in the sinking of a well at the Wolseley Park Reserve in town. Well in Wolseley Park.

4395. What was your experience in that instance? The well was bored to 132 feet; there was 77 feet of tubing. Depth.

4396. Did they strike water before they got to 132 feet? I think they got the main supply at 105 feet.

4397. Why did they sink lower? We were in hopes of getting an artesian supply.

4398. Was the water at 105 feet good? It is used by the people in the vicinity of the well for drinking and other purposes; it is 27 feet from the surface. Quality.

4399. Then it is artesian? To a certain extent.

4400. Where does the water rise from? I should think about south south-west of the town. Source.

4401. From hills close by? Yes.

4402. You do not think it has come from any distance? No, I do not.

4403. The finding of salt water in the well on your own property and the finding of good water in the wells close to it would lead you to suppose that the strata of water were different? Yes. Water strata.

4404. Do you think that the water passes through minerals? Yes.

4405. Is there any gypsum about there? I have not heard of any; the majority of wells contain a good deal of salt water. Salt water.

4406. *Mr. Murray.*] What is the depth of the well in which you obtained the salt water? About 30 feet. Depth.

4407. You did not think of sinking to the same depth as that of the other wells in the hope of getting a supply of fresh water? No, I did not.

4408. *Mr. Franklin.*] Did you preserve any of the material at the level at which you found the salt water? No; it is some three years ago; the well was filled in and the remainder of the material was carted away.

4409. Have any persons in this district kept for analysis the material in which they have found salt water? I do not think so.

Mr. John Hawthorn called in and examined :—

Mr. J. Hawthorn. 11 May, 1885.

4410. *President.*] Do you live in the neighbourhood of Gunnedah? Yes.
4411. You are a farmer? Yes.
4412. What area of land do you hold? About 700 acres, conditional purchase.
Area. 4413. Any other land—pre-emptive? Yes.
4414. What area altogether? About 1,200 acres.
4415. Do you live near the river? About 6 miles from it.
Country. 4416. What sort of country is it? It is plain country. I am off the plain, on a slight incline towards the bottom of the mountains.
4417. Is it much above the river? From the Mooki to where my land commences it seems to be pretty level, and from there to the bottom of the hills there is a slight incline.
Levels. 4418. Have you taken any levels to ascertain the height? No.
Cultivation 4419. Have you much land under cultivation? About 40 acres.
Season. 4420. Is this a bad season? I cannot complain of it.
Irrigation. 4421. If you could obtain water for irrigation would you be anxious to do so? I certainly would, if it came within my power to pay for it.
Water rate. 4422. And in proportion to the benefit you were likely to derive you would be prepared to pay? Yes; for this reason,—that in the last two years I have lost a great number of stock from the want of water.
4423. Then you would be prepared to pay for water even for the purpose of filling up tanks and dams? Yes; not only for crops, but for grazing purposes and for stock.
4424. Have you had any experience of irrigation? I cannot say that I have.
Wells. 4425. Have you sunk any wells on your property? Yes, I sank a well upon the property upon which I am now living. I went to a depth of 80 feet, and there I got brackish water.
4426. Did you sink lower? The water was too bad for use.
Tanks and dams. 4427. How do you supply yourself? With tanks and dams.
Rock. 4428. What sort of strata did you pass through in sinking the well? It was soft sinking—the stone was a sort of reddish colour.
4429. Do you know gypsum? I cannot say that I do. When the material was exposed to the air it crumbled away.
Supply. 4430. What quantity of water was there? A very good supply.
Stock. 4431. Would not the stock drink it? Some would, but they did not do well on it; some would perish before they would drink it.
4432. Did you sink wells in other places? No, I did not try. I have sunk wells on the Windebar run, over the range from Gunnedah.

TUESDAY, 12 MAY, 1885.

At Narrabri.

Present:—

MR. FRANKLIN, C.E., | MR. MURRAY, M.P.,
MR. LYNE, M.P., | MR. M'MORDIE, B.E., C.E.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. George Gregory called in and examined :—

Mr. G. Gregory. 12 May, 1885.

4433. *President.*] Where do you live? Bullawaa Creek.
4434. How far is that from Narrabri? 5 miles.
4435. Have you a farm or a station? A farm.
Area. 4436. What area? I have three farms; about 500 acres altogether.
Frontage. 4437. Is it a frontage? It is a frontage which takes Deep Creek for a mile and three-quarters.
4438. On each side of the river? On the north side.
Deep Creek. 4439. Is Deep Creek an ana-branch of the Bullawaa Creek? Yes.
4440. On the Narrabri side? Yes.
4441. Does it run in at a different point from the Bullawaa Creek? Yes, at angles.
4442. Have you been farming to any extent? I have been farming during the last twelve years, but in
Wells. 1860-1-3 I was dam-making and well-sinking on the Killarney Run near Narrabri.
4443. To what depth did you sink wells, as a rule? I sank one well on the Bobbiwa Creek at the foot
Spring. of the mountain, about 2 miles below the original spring.
4444. What was that spring like? It was a constant running spring up to within a few years ago; it
Supply. was always on the surface.
4445. A great quantity of water? Yes.
4446. How long has it ceased running? I cannot say exactly, but during the time I was there and previously it had never been known to be dry.
4447. Did it appear on the plain or in the mountain? On the mountain.
Spring. 4448. How far up in the plain? About 6 miles from the edge.
4449. Was it ever opened out? I was sent up to open the spring; I partly opened it, but I found that the water penetrated underneath and then I stopped the work.
4450. How did you find that out? When I reached the bottom I knew that it was porous underneath, and that the water went underneath instead of coming up.
4451. How long is it since you did that? In the drought in 1862.
ource. 4452. Has the spring been running since? It ran for years afterwards.
4453. Have you any idea where the drainage comes from? It was a main spring from the Saddle Mountains above it. It showed on the top of the ground in a place above. There is another spring some 4 miles above.
Strata. 4454. How far was that spring from Narrabri? I should think about 19 miles.
4455. What did you find in the wells which you sank in the creek below it? Gravel and boulders down to about 18 feet, and then I came to the rock.
4456. What kind of rock? Soft sandstone.

Mr. G. Gregory. 12 May, 1885.

4457. Did you get any quantity of water? No quantity; there was a small soakage on top of the rock.
4458. Did you sink through the rock? I went down 65 feet in it.
4459. But you did not get through? I found the rock getting harder, and then I came to the conclusion that it was the bed rock, but in the meantime I could hear the water running from the well on one side.
4460. Where were you sinking? I was sinking in the rock; after I got into it I could hear frogs croaking and water running. Frogs.
4461. Do you suppose that the sounds came from the interior of the rock? From the top of the rock. I concluded that I had had a rise in the rock, and that the water was running on one side. Sounds.
4462. Did you attempt to drive? I did drive. I spoke to Mr. Doyle and advised him to drive; I drove some distance, and he then said "We will leave this well and sink another on the other side of the creek." I said, "You will hit the rock." We sank on the other side and hit the rock. He was not satisfied to sink where I wanted to do so in order to strike the water which was running, and the place has not been tested since. The drive is still in the well. Driving.
4463. You know nothing more about that well? No.
4464. What kind of country was it about the well? Apple-tree, box, and ironbark. Country.
4465. On the foot of the ranges? Yes; it was the main creek running up the range from the plains.
4466. Did you sink any other wells in the neighbourhood? I sank the Killarney well; it went dry, and I had to sink it a few feet more. Killarney Well.
4467. What was the depth? 28 feet. Depth.
4468. And it went dry? Yes.
4469. How much deeper did you sink it? 2 or 3 feet.
4470. With what result? A good supply of water; there is a hard limestone ridge about there. Supply.
4471. Did that well go dry again? I cannot say; when I sank it the river was dry for a distance of 24 miles in one place.
4472. What kind of soil did you go through in the first instance? I believe that the greater part was limestone and black soil. Strata.
4473. Did you sink any other wells? Not there; I made several dams. Dams.
4474. Where is Killarney Station? About 4 miles from Narrabri, north from here.
4475. Have you sunk any wells anywhere else? I have sunk five or six where I am living at present. Wells.
4476. What strata did you go through? The first well which I sank was in the bed of Deep Creek. Strata.
4477. What did you find? Gravel for about 20 feet and then pipe-clay for about 15 feet, then gravel again for about 2 feet, then pipe-clay again, after that, gravel till I reached a depth of 75 feet.
4478. What did you strike then? Water.
4479. In any quantity? It is not a permanent supply. Supply.
4480. Simply drainage? Yes.
4481. How far out from the river? About three miles and a half.
4482. Do you suppose that the drainage is simply surface drainage? Yes. Drainage.
4483. You did not pass through any rock? No.
4484. Did you come on to any rock at the bottom? No.
4485. Where are the other wells? Another well was sunk in 1840, and it has never been known to be dry. Well, Spring Station.
4486. Where is it? It is at a place called Spring Station, on the Bullawaa Creek, about 300 yards from the well which I have just described; it is through sandstone and coal.
4487. Is it a spring? I believe it to be a spring. Spring.
4488. You have that well still? Yes.
4489. Are you using it? No; the water is hard. Quality.
4490. Does it rise to any height? I employed a man to bale it out; he worked all day with a 5-gallon bucket, and he only lowered the water 3 inches. Rise.
4491. You worked it with a windlass? Yes.
4492. For how long? Ten hours.
4493. What is the size of the well? About 4 feet by 4 feet; it is partly fallen in now; I wanted to bale it out in order to slab it afresh. Size.
4494. Were you ever down that well? No.
4495. Did you ever understand that there was a current in the well? I have an opinion that there is a current in it. I think that it is the main run of water from the mountains. Current.
4496. That is from the Nandewar Range? Yes.
4497. Have you ever tried the effect of the water on the surface—did it kill vegetation? It does not kill vegetation; we drink it, and use it for various domestic purposes. Effect on vegetation.
4498. Have you ever irrigated with it? For plants.
4499. Did it answer for that purpose? Well.
4500. Have you any other wells? I have another well which was sunk last year. Well.
4501. How far from the river? About the same distance—about three miles and a half.
4502. How far from the well just described? About three-quarters of a mile.
4503. In what direction? Nearer Narrabri, west from the other one.
4504. What depth is that one? 92 feet. Depth.
4505. Did you sink it yourself? Yes.
4506. What did you sink through? About 5 or 6 feet of loam, and then I came to the rock. Strata.
4507. The same rock? Sandstone; I followed it down 59 feet, and then I struck a seam of coal 10 inches thick. I forwarded a sample of the coal to the Minister for Mines. It was analyzed, and I was told that it would give a good return. I then came to the coal rock lying in joints underneath and impregnated with copper. I then went down through partly formed coal to the depth of 92 feet. I finally struck water in coal rock. Coal seam.
4508. Any quantity? At the time when I struck it it was not very strong, but since then I have been unable to lower it.
4509. In what direction did the water come from? From the mountains, through crevices of coal rock.
4510. What sort of water is it? Similar to the water in the other well; somewhat salt and hard like all coal water. Quality of water.
4511. Have you sunk the well deeper since? No; there are 32 feet of water in it now, and I cannot lower it. Depth.
4512. What is the size of the well? 4 feet by 4 feet at the top, and 3 feet 6 inches after about 60 feet. Size.

Mr. G. Gregory. 12 May, 1885.

4513. Do you raise the water by hand? We use 10-gallon buckets and a windlass.

4514. Have you any other wells? I have another at about 400 yards from this point, on the banks of Deep Creek.

4515. When did you sink that? About seven years ago.

Well. 4516. Will you describe it? There are about 17 feet of loam and then about 8 feet of gravel, afterwards 14 feet of pipe-clay, then gravel to the bottom; but the water is different from that in the other wells—it

Quality. is considered the best drinking water in the district.

4517. You did not come to the rock? No.

Rise. 4518. How high does the water rise? About 30 feet.

Soil. 4519. What is the nature of the soil on the surface? Sandy loam.

4520. Do you know the nature of the soil generally throughout the district? Along the foot of the mountains it is a porous sandy loam.

4521. What is the nature of the soil near the river? Clayey.

Holding ground. 4522. Is it good holding ground? When you get a certain distance from the mountains, if you go any depth in the clayey ground, you are likely to go through on to the loam.

4523. Is that near the river? No; it is good holding ground near the river.

4524. How far out from the river? I cannot say exactly; you will find good holding ground at Stony Creek.

4525. How far out does that go from the river? It does not go out above 4 or 5 miles.

4526. Keeping at a distance of about 4 or 5 miles from the foot of the mountains you will find very good holding ground in places, and from that point to the mountains it is porous? Yes.

Agricultural land. 4527. Which do you consider the best agricultural land? The porous land near the mountains by far.

4528. Is that porous land improved or does it yield more in proportion through having plenty of water? A great deal.

4529. Which yields most in consequence of plenty of water? The porous land—there is more chance of rooting in it.

Trenching. 4530. I suppose that if the heavy land near the river were trenched it would be good? It is good wheat land.

4531. And would be improved proportionate to the depth of the trenching? Yes.

4532. Have you been farming on your land? For twelve years.

Crops. 4533. What is your experience of crops? During the last ten years I have had a poor chance of growing anything, the seasons having been so variable, and we have been so short of water; we have been scarcely able to support ourselves.

Irrigation. 4534. During that time if you had had plenty of water to irrigate your land you would have had better yields? About four times.

Water rate. 4535. If water were placed within your reach and if you could obtain it at a fair rate would you be prepared to avail yourself of the supply? Of course if the water benefited us we could afford to pay a fair rate, because taking our seasons here as a rule we are never sure of a crop.

4536. What do you think you could afford to pay per acre if you were sure of getting good crops? I suppose that if there were a good supply of water a person could afford to pay £1 per acre. Of course he would benefit a great deal more than that by it.

Situation of land. 4537. Is your land so situated that you could prepare it for irrigation without incurring any great expense? Yes, the water could all be got on to the high land.

4538. Are there any other farms near you? There are 15 or 16 miles of farms on Eulah and Bullawaa Creeks.

Farmers on irrigation. 4539. Have you conversed with other farmers about irrigation? Yes, and I have found that a great many were inclined to make a start on their own account, but the seasons have been so bad that they have been unable to commence.

Water rate. 4540. Do you think that as a rule they would be anxious or willing to pay a reasonable rate for water? I believe that they would be only too glad to get it.

Extent of land. 4541. Have you any idea as to the extent of land on the north side of the river between it and the mountains? From Maule's Creek to Narrabri there is a distance of about 20 miles; it would average about 12 or 14 miles from the river to the hills up to Narrabri.

4542. That is, 20 by 12 or 14 miles? Yes.

4543. Is it good land? Yes.

Settlement. 4544. Is there any settlement near the range? From Berrioye downwards there are a large number of selectors.

Spurs. 4545. Is there a spur of the mountains at Maule's Creek? At Berrioye, on both sides, the mountains begin to close in on to the river, and after you leave Berrioye and work down towards Narrabri the mountains draw in again.

Selected land. 4546. Is there any other settlement apart from selectors at the foot of the mountains? There are sheep stations, but it is all selected land.

4547. Have you been about the mountains? Yes.

Natural basins. 4548. Did it strike you that there were any natural basins which, by the construction of dams, could be made to impound large quantities of water? I am afraid that the ground would be all too porous; it is mostly loose rock just under the surface.

4549. And you think that the water would get through that rock? Yes.

Depth to rock. 4550. At what depth is the rock from the surface? I could not say; a great deal of loose rock falls from the summits of the hills into these basins; I do not suppose that the depth to the rock would be more than 10 or 15 feet.

Gap at Bobbiwan Creek. 4551. Are the hills close to where the creeks come out? They are very narrow in places and the country opens out above; there is one place at Bobbiwaa Creek; the gap is not above 10 feet wide.

4552. What is the country like above? More open.

4553 Is there a large basin? The creek widens a great deal, and slopes on both sides.

4554. Is there any flat? Yes.

4555. How far does the creek run up above that point? 7 or 8 miles.

4556. For what distance do you suppose that it runs fairly flat? It does not run fairly level, but there is no great fall for some distance.

Dam. 4557. Would it be a great work to construct a dam of from 100 to 200 feet? Yes; the hills do not run that height.

4558. What is the height? From 40 or 50 to about 80 feet.

4559.

Mr. G. Gregory.
12 May, 1885.

4559. Do you know any similar places in the neighbourhood? No.
4560. Do you think that if water were stored at the heads of the creeks the country along the Namoi could be irrigated? Yes, you would have no trouble in irrigating it if water were stored above.
4561. Are you well acquainted with the country about Boggabri? No.
4562. Do you know anything about the country on the south side of the Namoi? Not a great deal; I have been over it.
4563. Does the land near Boggabri come down near the river? The rocks come right down to the river banks. Boggabri.
4564. Suppose a canal were brought down on the south side from near the head, could you not get past? No.
4565. Could a canal brought from the head of the river be brought down on the north side between the river and the hills? Yes, I think so; it would take a shorter cut. Canal.
4566. If that water were kept on a sufficient elevation near the hills it would command the whole of the plains below? Yes. Command of the plains.
4567. Have you put any dams in any of these large creeks? On the Bobbiwaa. Dams.
4568. What height? 23 feet. Height.
4569. Did you have a bywash? Yes. Bywash.
4570. Did the dam answer the purpose for which it was intended? It was timbered back and front, and when the water came down in full force to the depth of the creek it took the dam away with a sudden rush. Effect.
4571. What was the cause of the dam going? It was put in with dry earth and was not puddled.
4572. Do you think it possible to puddle such a dam across a large creek in such a way that it would stand? Yes.
4573. Would it be possible to put a dam across the Namoi which would stand? I think so, if you formed some place in which the water could get away. Dams across Namoi.
4574. A bywash or sluice? Yes.
4575. Do you know any ridges of rock which run across the river about here on which a dam could be placed? There is one which they call the Rocky Crossing. Rock bars.
4576. How far from Narrabri? Above it.
4577. About what height are the banks of the river there? 15 or 20 feet. Banks.
4578. Would a dam placed there fill up a large area with water? Yes.
4579. Where is the nearest stone which could be used in its construction? There is blue-metal at the Little Mountain and freestone at my place. Building material.
4580. Does the trap-stone run in large blocks at your place? Very large; in fact, there is a mountain of it.
4581. If it had to be quarried? Yes.
4582. Has it struck you that the country along the banks of the river is higher than that at a distance from the river? All the way nearly. Formation of banks.
4583. What do you suppose is the reason of that? The wash from the river; the earth washed up by the rush of water is thrown up on two sides.
4584. Suppose water could be raised by dam to the height of the river bank, would it reach an elevation which would command a great deal of the country back from the river bank? Yes. Effect of dam.
4585. *Mr. Franklin.*] Have you observed the creeks in the loose country over the hills? Yes. Creeks.
4586. Do you think that there is much soakage in the creeks during the time of discharge? Yes; in one or two of the creeks there is a heavy run underneath. Soakage.
4587. You do not find a clayey deposit in the creeks brought down from the mountains? None that tends to make them tight. Deposit.
4588. In your opinion, a canal or channel on the slope could not be made tight by gravitation of clay into it? It would puddle itself in time; the loam is so very fine that it could not help doing so in the course of time; there are places at the foot of the mountains where water will stand for a considerable time after sheep have been on the land. I think that a canal could be puddled to carry water on to the clayey ground.
4589. What is the height of the slope above the general plain? At Bobbiwaa, from 80 to 100 feet. Slope.
4590. *Mr. M'Mordie.*] In the porous basins could not the water be stored by carrying up a dam from the solid rock? Yes; you would have one natural side afforded by the formation of the land. Dam.
4591. *Mr. Murray.*] In the wells which you sank did you notice any underground current? Only in one; I believe it is an underground current. Underground current.
4592. You do not know of any near Narrabri? None except the one at Bobbiwaa which I have mentioned.
4593. What is the average depth to which they sink in the town of Narrabri? From 18 to 30 feet. Depth of wells.
4594. *Mr. Franklin.*] Is there a site about Narrabri where rough rock is seen cropping out above the banks of the river? On the south side; it is of a clayey nature on this side. Rock.
4595. What is the width of the river at that point? The bank is low on this side, and on the other side prominent; the width is from 80 to 100 yards. Width of river.
4596. How far back do you go on the low side before reaching the level of the high side? A considerable distance; it is a gradual slope; to gain the last 5 or 6 feet you might have to go a quarter of a mile. Banks.
4597. What is the maximum rise in flood-time in the highest flood you have known at that site? I should say about 12 feet above the banks; the flood of 1864 was the largest which I have seen in the Namoi. Flood levels.
4598. Have you observed the floods from time to time? From 1860 to the present time.
4599. Have you made any permanent marks? No.
4600. Could you show any of your marks to an officer of the Commission? Not on my own land; I am out of flood reach; I have seen the land near Narrabri under water several times.
4601. Does much water come down the tributaries from the mountains in flood-time? A great quantity. Flood-waters.
4602. You think that it might be intercepted? Plenty of it; there are plenty of places where tanks could be made in clayey ground under the foot of the mountains; by carefully selecting the sites you might with little trouble turn the water from the creeks to fill reservoirs.

Mr. Charles Alexander Ross examined :—

Mr. C. A. Ross. 12 May, 1885.

4603. *President.*] Where do you reside? At Narrabri.
4604. Have you lived here any length of time? Twenty-five years.
4605. You must have an intimate knowledge of the whole district? Yes.

Floods.

4606. And of the floods which have taken place here? Yes.
4607. What extent of country is under water at the time of high flood from the Namoi? Below Narrabri I have seen the water 8 miles wide, but it is narrow except where it is intersected by watercourses.
4608. Have you any station or farming property here? I have none myself.
4609. Have you been living in Narrabri all this time? I have been living in Narrabri for the last five years.
4610. Have you any idea of the area of country lying between the Namoi and the range of mountains on the north side? I have as far as Maule's Creek—I know the country intimately as far as that point.

Available land.

4611. What area of available land is there? I should think back from the river a distance of 15 or 16 miles in some places; that would be about the average.
4612. Do you think it good land? Some of it very good indeed.

Effect of droughts.

4613. Has it been suffering much in dry seasons? During the last five years, to my certain knowledge. I may say that I have been engaged in a business which is dependent on the crops up the creek—I have a mill here.

Produce.

4614. Can you give us an idea of the quantity of grain produced round about Narrabri? The quantity produced during the last four seasons has been very small.
4615. To what do you attribute that? To a certain extent to the dry weather.
4616. What is the other reason? The small quantity of land put under grain.
4617. Supposing crops could be assured, do you think a large area would be put under grain? I think so.

Settlement.

4618. Is there a large settlement in the neighbourhood? There are a large number of settlers, most of whom have very small holdings.
4619. Of course, then, there is the greater necessity for them to obtain as much as possible from their land? I should think so. Many of them have not the capital to enlarge their holdings and to clear their land.

Effect of water supply.

4620. What is your opinion of a water supply which might be more within their reach—would it be of great service? I think the land is good enough to produce any crop if they could get a good supply of water. Following up the course of this creek you can find as good land as any in the country.

Natural basins.

4621. Do you think that at the heads of this creek there are any large natural basins in which water could be impounded? I think so. Wherever you find rocky bars crossing the creeks I should think you might be able to impound water to a considerable extent.
4622. But it is beyond the capacity of these persons, for financial reasons, to do anything for themselves on a large scale? I think so—quite impossible.

Water Trusts.

4623. Do you think that in this district between the Namoi and the ranges there is a sufficient settlement to form a Trust for the conservation of water in the mountains? I think so.
4624. Supposing they could obtain the money from the Government to do such a work at a reasonable rate, would they be willing to undertake it? I think so, most undoubtedly.

Water rate.

4625. From your conversations with the residents of the district, do you think they would avail themselves of a water supply and would be willing to pay a fair rate for the use of the water? I think most of them would. I may say that within the last year or two the cultivation of land has fallen off in the district.

Sheep farming.

Some persons who were cultivating land have gone into sheep-farming. That has been the case, I think, in most instances where people have had the money to enlarge their holdings—they have preferred sheep-farming to agriculture.
4626. Would that be the case if they could be sure of their crops? I think not.

Price of wheat.

4627. In this district is wheat at a price which would pay for its growth? Yes; it is a little better here than at Tamworth, the difference is the railway carriage between here and Tamworth, giving it a slight advantage.

Wells.

4628. Have you had any experience of wells in this district? I had up at Bullawaa Creek some eighteen years ago. I was an overseer there, and we had several wells sunk upon that creek.

Quality.

4629. With what result? A good supply of water at from 25 to 30 feet.
4630. Was it good water? Very good water.

Source.

4631. Was it simply a soakage supply, or do you suppose a spring to have been struck? It was hardly spring water—it did not rise after it was struck; it was more in the nature of an underground current.
4632. Where do you suppose it rose from? At the head of the creek, inasmuch as by following the creek up, even in dry weather, nearly to the head you could always get running water.
4633. Are there wells sunk in or near the bed of the creek? Close to the creek—in most instances within 60 or 70 yards.
4634. Do you know of cases where wells have been sunk at a distance from the creek? No, I do not.
4635. Have you any knowledge of the extent of water flowing underground from the hills—that is to say, as to the width? No. I have seen wells sunk on the opposite side within 150 or 160 yards of one well which we had sunk, and where they went 80 or 90 feet without striking water.
4636. Do you know of any instance where the sandstone spoken of by the last witness has been driven through in sinking for water? No.
4637. Have you had any experience of wells on any of the other creeks? I have had a great deal of experience in the sinking of wells out in this direction. I once managed Dobbikin and Woollabrar Stations; they were comparatively dry in the summer. I sank altogether nine or ten wells and trial-shafts on this station without getting a supply of water.

Depth.

4638. To what depth did you go? 136 feet was the deepest.

Supply.

4639. Did you strike good water in any of the wells? I struck good water in one well, but there was a very small supply of it.
4640. Was it simply soakage? Yes.

Quality.

4641. Was it good water? Very good water.
4642. Is that the only well from which you got water? The only well.

Depth.

4643. At what depth? I struck water first at a depth of 43 feet. We afterwards sank to a depth of 103 feet, but we got no further supply.
4644. Did it flow up all the distance down? At times there was a slight soakage.

Mr. C. A. Ross. 12 May, 1885.

4645. Do you know the Geehan Creek? It is about 30 miles north of Narrabri; it is afterwards known as the Waterloo. That creek runs into the Thallaba, which runs into the Barwon.
4646. Between Narrabri and the Geehan Creek there is a dividing watershed? There must be a division in the watershed, but there is no high range. A stream of water conveyed along the high land between the Namoi and the Geehan Creek would command the country on both sides. I may tell you that from Wee Waa to Thallaba Creek the country is almost level. In the 1864 flood the water was out past Boolcarrol about 20 miles. Flood in 1864.
4647. Are there any dry lakes out in this country between the Namoi and Geehan Creek? Very shallow ones; no deep lake in which any large quantity of permanent water could be stored. There are five or six shallow lagoons. Lakes.
4648. What is the nature of the country—is it good soil? Good grass land. Country.
4649. Would it be suitable for agriculture? I hardly think so. I have no doubt it would be splendid land for agriculture if there was a good supply of water, but it would take a very large supply.
4650. Why do you think so? I have cultivated a little, and I have found that it took a very large supply.
4651. Is the land of a clayey or of a porous nature? It is clay.
4652. Where did you get the water when you were endeavouring to cultivate? From the Geehan Creek.
4653. How long ago? Between 1866 and 1877.
4654. Did you attempt to irrigate to any great extent? Only to a small extent, for a garden. Irrigation.
4655. Did you trench the land? Yes.
4656. What depth of water would it absorb before you derived any good from it? I should say about 3 or 4 inches. I never took any note of the quantity of water I used.
4657. What is your estimate of the difference in the productiveness of soil which is irrigated and soil which is not irrigated—I am speaking, of course, of the extent to which you irrigated it? With non-irrigation in the summer you would get nothing at all; with irrigation I could get a good crop of lucerne and other produce of the kind. Productiveness of soil.
4658. Did it ever come within your experience to find any quantity of water driving from the hills over the bed-rock, or at any depth below the surface? No. About a mile and a quarter from the spot at which I sank the first well at Woollabrar they sank in Myall Hollow a well in which they obtained at 43 feet an ample supply of water. Wells.
4659. Was it good water? Very good water. Quality.
4660. Did it rise in the well very much? No. Rise.
4661. Was it an inexhaustible supply? Almost. They used to let down 250-gallon buckets, and they were filled in a few minutes. Supply.
4662. What is the size of the well? 8 feet by 8 feet. Size.
4663. What was the depth of the water? About 7 feet. Depth.
4664. How did they work? With horses and a whim. They used to work very heavily, sometimes using three horses in a day. Working.
4665. Did they think there was a flowing stream? I was under that impression, and so were several others. Current.
4666. From the hills to the flat country? Yes.
4667. Do you know of any place where such a stream might come out and disappear lower down? No.
4668. Then the water does not rise again anywhere within your knowledge? Not to my knowledge.
4669. At any rate it would be a great distance before the water rose again? Yes. Seeing that they had obtained so good a supply of water, I sank seven trial shafts across what I thought to be the course of the stream, to try to intercept it.
4670. Did you strike the stream? No, I only got a soakage. Soakage.
4671. At what conclusion did you arrive? That the water ran in a narrow channel and that I had failed to find it, or that the strata in which the water was running dipped very suddenly from the well in which it had been found. Channel of under current.
4672. Are there any clays or rock in that neighbourhood which would keep the water down and cause it to dip suddenly? No, this well was in the flat country. From Myall Hollow the country rises both east and north slightly. There are rolling downs covered with trap boulders. Nature of country.
4673. Is it volcanic? To the north and east.
4674. But the water is flowing to the south and west? Yes, I imagine so. Direction of flow.
4675. Has any one else ever struck the same water? Not to the westward of it.
4676. Have they struck it at all? To the east.
4677. Is it the same water? I believe so. It is struck at a higher level going in the same direction south and west.
4678. *Mr. Franklin.*] Do you know the course of the Namoi from the junction of the Manilla? No, I do not know the course of the Namoi much beyond Boggabri. The Namoi.
4679. You know the part near Narrabri well? Yes.
4680. After a considerable drought what is the state of the river at that point? From Broadwater I have known it to stop running altogether; that is a distance of 12 or 14 miles from here.
4681. In that distance are there considerable reaches of water still in existence? Not within that distance. There is a large reach of water just beyond Broadwater. Reaches.
4682. Are there any waterholes in that distance? There are some now. Water-holes.
4683. What is the nature of the deposit in the bed of the river between those waterholes? Sand and gravel. Deposits.
4684. Do you know whether any attempt has been made to draw water from these sandy deposits? I do not.
4685. You do not know that they have touched the water at any depth? No.
4686. *Mr. Murray.*] Do the floods which you have mentioned remain long over the country? The only flood which I know thoroughly well was the flood of 1874; then the water remained at its greatest height for five days. Floods. Duration.
4687. Did the great body of the water escape by the bed of the river or through the ground? I think through the ground; the body of the river does not seem to cover one-third of it. Escape.
4688. From that you conclude that there is a great underground supply? I imagine so. Underground supply.
4689. Have you heard of any wells in that neighbourhood in which running water is tapped? No.

Mr. C. A. Ross. 12 May, 1885.

4690. Is the flow of water which escapes very large? In flood-time.

4691. To what do you attribute the small number of agricultural farms here? To the uncertainty of the crops.

4692. If you could be supplied with water those crops would be greatly increased, would they not? I think so.

Crown lands. 4693. There are plenty of Crown Lands? Yes, and some of the land is very good, quite equal to the land on the Hunter.

Escape of water. 4694. Do you know of any point on this river where the water seems to get away when it is low: supposing there is a good body of water up the river and a small body below, do you know of any point between where the water could get away into underground strata? I do not.

4695. Has it been noticed that in a dry time the volume of water down the river was less than at a certain point up the river? Yes, below Wee Waa the river is small in comparison with the river here.

Sandy bed. 4696. It is a sandy bed? For miles it is sand and gravel.

4697. And does the water appear again on the surface, or does it get away altogether? I think it gets away altogether.

4698. You think that at a point somewhere between this place and Wee Waa it gets away altogether by soakage? Yes.

Mr. Charles Eather called in and examined:—

Mr. C. Eather. 12 May, 1885.

4699. *President.*] You live in the neighbourhood of Narrabri? In Narrabri itself.

4700. For many years? Since 1841.

4701. Have you lived in Narrabri all that time? Nearly. I have lived on a station at Henriendi.

4702. You have seen all the floods in the river during that time? Yes, a great many.

Floods. 4703. Did they extend a great distance out from the river? Yes, down this way, but they did not higher up.

4704. Does the country rise to a height to prevent their extension far out? Yes, it is a basin. It spreads a good deal on this side of the Rock; at Turrawan it spreads most on the northern side of the river.

4705. Is that above Narrabri? 15 miles from here.

4706. What does the Rock take its name from? The proper name is Coobabindi.

4707. Is that on the south side? No, it is on the north side; it is a ridge coming right into the river.

4708. It would prevent any canal being brought past that point from a point higher up? Yes.

4709. From that point it spreads out on the north side? Yes; you get down 5 miles and then it spreads out.

4710. What is the width in flood-time? In 1864, at this side of the Rock, I believe it spread out to 20 miles, at Baanba 8 miles, and at Baanba North 12 miles.

4711. How much does it increase lower down towards Narrabri? It increases more and more—I have seen it 30 miles wide. On the south side it does not spread much for some distance, but on the north side it spreads a great deal.

Nature of soil. 4712. What is the nature of the soil down the river from and above the Rock? Black soil in places. At 1 mile on this side of the Rock from one ridge to the other, including the river passing through it, there is a width of half a mile.

4713. What kind of country is it above there—is there any good country? Yes, this side of Guligal and this side of Gunnedah.

4714. Above that point on the south is there any extent of good country? Not till you pass Boggabri, 4 miles above the Rock.

Dam. 4715. Supposing the river were dammed at this point, would it throw back a large quantity of water above? It would spread it out on the north side immediately, but it would not do so on the south until you get 4 miles up.

Area. 4716. What extent of country would be covered with water on the north side? An average of about 12 miles.

4717. How far would it run back if it were raised 50 feet above the fall of the country? It is pretty level; there is not much of a fall just there. I could not tell exactly how far back the water would go; it is a question of levels.

Command of country. 4718. Supposing any work of that kind were carried out, would the water impounded there command the whole of the country in this direction? I think it would.

4719. Have you any knowledge of the hills about here? Yes.

Natural basins. 4720. Have you been up the creeks which come from these hills? Yes.

4721. Did it ever strike you that large quantities of water could be impounded in natural basins at the heads of these creeks? I never thought of such a thing.

Snow. 4722. Is it usual for snow to lie on the mountains? I have seen it do so at times.

4723. But not to any great extent? I have seen it only two or three times since I have been here; then the hills have looked as white as paper.

Wells. 4724. Does it lie for any length of time? I think I have seen Mount Lindsay white for about a week.

4725. Have you had any experience in well-sinking in this country? Very little.

Underground streams 4726. Have you heard of any underground stream of water which apparently runs from the hills to the lower country? I have known creeks to run underground for some distance and then rise again.

4727. Have you known of an extensive stream of water which loses itself and does not reappear? No, I have not.

Farming. 4728. Do you think that any extensive farming operations would be carried on here if the farmers had the advantage of water supply? I do.

4729. Do you think they would avail themselves of a supply of water if they could obtain it at a reasonable cost? I do.

Irrigation. 4730. You have had no experience in irrigation? I have had none. I know that the land will grow anything if we can get water.

Banks. 4731. Did it ever strike you that the country on the banks of the river is higher than the plains away from the river? Yes.

4732. You do not know the reason? I cannot account for it.

4733. If the water were dammed in the river to the height of the banks, could a great deal of country along the banks be irrigated? I should think so. Mr. C. Father.
4734. *Mr. Franklin.*] At a place called the Rock, does the rock crop across the river? No, it comes down to within a few yards of the river. 12 May, 1885.
4735. What is the nature of the deposit in the river at that side? It is gravel. Deposit.
4736. Below that point there is a creek called Maule's Creek? Yes. Maule's Creek.
4737. Is that deeply cut in the alluvial? No, it is not.
4738. Is there a great fall in that creek towards the river on the flat? No; there is a great fall higher up. I have known the water to come down with such speed that it has run up the river the wrong way for 7 or 8 miles. Fall.
4739. It would be a kind of back-water? Yes.
4740. There is a tributary to that creek known as the Horse Arm? Yes. Horse Arm.
4741. Is it not shallow at the junction of that tributary? It is.
4742. It would give you the idea that the ground is lower there than when you approach the river? It does.
4743. Do you know of any obstruction on either side which would interfere with the formation of a canal? I do not think you can form a canal up there above Broadwater. Canal.
4744. If a dam were made at that site, would there be any probability of the water flanking the dam? It could not get round. Dam.
4745. You are acquainted with the course of the Namoi between Narrabri and its junction with the Manilla? Yes. River from Narrabri to Manilla junction.
4746. What would be the saving of distance if you took a direct cut from the junction of the Manilla to this point, as compared with the course of the river? I have gone from Henriendi to Manilla in about 40 miles.
4747. Does the bed of the river change much in the time of flood—is the silt deposit shifted in large quantities? I know of some places where there are big holes which have never been known to be filled up during flood. Silt.
4748. *Mr. Murray.*] I suppose the greater supply for the Namoi is from the Nandewar Range? From Manilla, and up that way. Supply.
4749. Where do the great floods which spread over this country come from? From the Bendemeer, the Peel, the Mooki, Cox's Creek, and other watercourses in that direction. Origin of floods.
4750. In this locality, could the tributaries of the Namoi coming from the Nandewar Range be intercepted and made to store a large quantity of water? If that were done I think the population would increase a great deal, and Crown Lands which were suitable to agricultural purposes would be taken up. I also think that the pastoral tenants would be inclined to make use of the water, and would be satisfied to pay a reasonable rate towards the expense of storage. During the last few years we have lost a great deal of stock from drought; within the last seven years hundreds of thousands of stock must have died from that cause. Water storage. Loss through drought.
4751. I suppose they would not object to pay a rate equivalent to about one-quarter of the value of their loss, in order to prevent that loss altogether? No. Water rate.
4752. *Mr. M'Mordie.*] If water were available for irrigation, what would be the principal crops grown in this district? The most difficult thing to grow here is maize, but we could grow that with plenty of water; the other crops would be wheat, barley, lucerne, pumpkins, potatoes, and all other sorts of vegetables. Irrigation crops.
4753. At what season of the year would water be required for those crops? It would not be required every year.
4754. But in dry seasons? From spring to autumn.
4755. You would not want much in the winter? A very little rain suffices in the winter. Rain season.
4756. When are your principal rains? They used to occur in February, but now we get none at all at that time. The heaviest rains are generally in February and March—not in the winter-time. The largest floods we have had have been in those months.
4757. *Mr. Murray.*] Is the country at Boggabri very poor? No, it is very good.

Mr. Charles Collins called in and examined:—

4758. *President.*] You are the Mayor of Narrabri? Yes.
4759. Have you lived here long? Eighteen years. Mr. C. Collins.
4760. What is your opinion of the land in the valley between the Nandewar Range and the river? It is splendid land; most of it is fit for agriculture. There is a large quantity of land open for irrigation between this place and Walgett. If a water supply were carried out, most of the land would be under the control of any water which might be impounded. There is a large settlement in the neighbourhood of Narrabri. 12 May, 1885. Quality of land. Settlement.
4761. At what points? Underneath the ranges and along the river on the north side.
4762. On the south side too? Not so much; the land is not so good until you get past Pilliga.
4763. Do you think the population would increase to any great extent if the crops were ensured by a supply of water? I am certain of it; that is all we want to make it a good country. Increase of population.
4764. You are well acquainted with the course of the Namoi? I know it from here to Walgett, and from here to Gunnedah. The Namoi.
4765. Have you noticed that the banks along the river are higher than the back country? I think they are. Banks.
4766. Can you account for it? In flood-time the earth is thrown up and remains there.
4767. Is it possible to dam the river at various points? Yes; it was suggested to me a few years ago to open a scheme which would permit of irrigation, but we found that it would cost too much money and we abandoned it; it was beyond the means of the people in the district. Dams.
4768. Do you know of any rocky bars at which dams could be thrown across the river? There is one about 3 or 4 miles up from Narrabri, also down by Yaraldool, and others at Bugilbone and Mille. Rocky bars.
4769. Are the rocks laid bare in the bed? Yes, you can see them.
4770. Do they rise from the river on either bank? They do at Yaraldool.

Mr. C. Collins. 12 May, 1885.

4771. If a weir were thrown across the river, would it prevent a new channel from being formed? I think you might put it across the river there without any danger of a new channel being formed.

4772. Then you think it would be quite practicable at various points to dam the river by means of weirs with a sluice and yet avoid the formation of new channels? I do.

4773. You think the nature of the land is such that it will stand a weir? I do.

4774. Supposing that were done and no locks were put in the river, would any injury be done to communication, provided a railway were run in the neighbourhood of the river? Certainly not.

Navigation.

4775. Do you think that a railway from Narrabri to Walgett would obviate the necessity of keeping up the navigableness of the river? We all know that water carriage is far cheaper than railway carriage. The Member for the district has endeavoured to get the river snagged on this side of Walgett. There is no doubt that if that could be done water carriage would be far cheaper, but I do not think it would do away with the necessity for a railway.

4776. If a line were constructed, would there be any necessity for snagging the river? I do not think there would be any necessity.

4777. Then the throwing of weirs across the river at various points would not be so objectionable? Certainly not.

Irrigation.

4778. Do you think that the navigation of a river should take precedence of the use of the water for irrigation? Not in this dry country.

4779. Supposing the river were dammed at various points, do you think that the water would be used for irrigation in the vicinity of the river? I think so.

4780. Do you think that, where the country is in the hands of large proprietors, the water would be utilized to any extent for the growth of crops for reserve feed in time of drought? Certainly.

Fodder. Loss in stock.

4781. If a large quantity of fodder were grown and reserved, would it have the effect of preventing the great mortality of live stock which takes place in dry seasons? I think that there is no doubt about it. During the last two or three years about £200,000 has gone out of the district for forage. Of course it would only save the large stock—it would not save the sheep.

Market. Price of forage.

4782. Supposing the country higher up the river were placed under irrigation and crops were grown, would there be a larger market here if prices were reduced to keep the stock alive in dry seasons? I think there is no doubt of it. There would be a great advantage in having a line constructed to Narrabri from this place for the purpose of getting forage out to stations at the back. Sometimes they pay as high as £15 or £20 a ton.

4783. That is a price which is beyond the reach of graziers for the purpose of keeping sheep alive? Yes. The sheep have been kept alive principally by cutting down the scrub.

Agricultural land.

4784. Have you any idea of the area of good land which would be brought under agriculture in the valley between the Namoi and the Nandewar Range if a system of water distribution were adopted? I think the whole of the land on this side of Walgett—on that side of the river—would be brought under cultivation.

4785. What is the distance? About 120 miles. It would be 50 miles in width.

Area.

4786. What area of land from Narrabri upwards would be brought under cultivation? On the north side, I suppose nearly the whole of the distance from Narrabri to Gunnedah.

4787. To what distance? About 50 miles.

4788. What would be the average width? From 12 to 15 miles.

The Gehan

4789. One witness to-day said that when you got about 20 miles from the Namoi the water fell towards the Gehan? Yes; that is on the road to Moree.

4790. Is the country from the Namoi to this creek good? Yes.

Ball Hill Ridge.

4791. There must be an elevated ridge between the Namoi and that creek? I suppose there would be; at a distance of about 20 miles there is a ridge on the plains called Bald Hill, and there are some other ridges further on.

4792. These ridges would divide the watershed? I suppose so.

4793. Are the ridges continuous? The one called the Bald Hill is a large mountain of stones.

4794. The elevation is higher than the Namoi and the creek? Yes. A supply of water on that ridge would command the country on both sides.

Thalaba Creek.

4795. How far does the Thalaba Creek run down? I have not been down there. I believe it runs about 50 miles to its junction with the Barwon.

4796. Throughout the whole of that distance the country is of a nature which would permit of the carrying on of agriculture? Yes; all that is wanted is water.

Distribution of water.

4797. If we connected the lower ridges, could we discharge the water around them? There is nothing to prevent the discharge right or left.

Underground supply.

4798. *Mr. Murray.*] Do you know of any underground supply which is proved by well-sinking? It has been found, I think, that when the creeks and rivers got low the wells have also got low, and that when the water has risen in the river the water in wells has also risen.

4799. That is in the neighbourhood of Narrabri? Yes.

Wells in river-bed.

4800. That leads you to suppose that the water comes from the river? Yes.

4801. *Mr. Franklin.*] Have they attempted to get water from the deposits of sand in the river bed? Last year we made application to the Minister to have some wells sunk in the river between here and Walgett. I believe the water could have been got at about 12 feet, and at some places at a less depth, but that is about the average.

4802. What means would you employ to keep out the sand when you were sinking? I think it could be done by putting down timber. The squatters have some dams along the road, and they have allowed carriers to take water. It becomes a very serious matter in these dry seasons.

4803. You do not know whether water is to be found in the open ridges at the same level as in the sand? No, I do not.

Mr. John Brake called in and examined:—

Mr. J. Brake. 12 May, 1885.

4804. *President.*] Where do you live? On the Deep Creek.

4805. Do you live near Gregory? About a mile from him.

4806. What evidence are you in a position to give to the Commission? I can give them information as to well-sinking. I have sunk a well at my place, and I have been trying to irrigate. I am down to 38 feet in the drift. I boxed the well for 4 feet 6 inches, it being 3 feet 6 inches in the clear. It was too small for working and prevented me from getting down lower. I am now erecting a windmill—it is nice soft water—close alongside of the bank of Deep Creek.

Wells. Deep Creek.

4807. Is the water coming along the drift of the creek? It is too low; the creek is not more than 15 feet deep. There is an arm in the creek there, and I am on the point. I cut drift and sand when I was about 4 feet from the surface; that went down to 40 feet; from that I got a seam of clay to 63 feet, and then gravel and cement; the water was on the top of the cement. Mr. J. Brake. 12 May, 1885.

4808. That is the water you are using? Yes, some of it. After I broke through the cement it became looser until I reached my present level. I had to screw the box down in order to work. The water rose up to the level at which I first struck it; it ran along the cement under a band of clay. Rise.

4809. Did it rise at all when you first struck it? Not more than 18 inches.

4810. Have you prepared any land for irrigation? About 14 acres. Irrigation.

4811. In what way did you prepare it? It does not need much preparation; there is a natural fall for gravitation.

4812. Is it very steep? There is a very little fall. About 3 or 4 chains from the well there is the greatest fall, and then there is just enough for the water to run and that is all. Fall.

4813. What area would that command for irrigation? About 50 acres belonging to me. I have only 98 acres. Area.

4814. Do you consider that if you could command 50 acres it would give you sufficient farming land on which to live? That is my impression.

4815. What area can you live on as the seasons now are? Anything under 1,000 acres is not of much use; it is very hard to get a living out of that.

4816. Then you consider that the advantage of irrigation is so great that, whereas you could not live on a farm of 1,000 acres without irrigation, a farm of 100 acres would be sufficient if the land were irrigated? Yes. To show you the advantages to be derived from irrigation, I may mention that I had three-fourths of an acre of grapes. Last year we had not quite the average rainfall of 18 inches; the year before from April to April, we had only 3½ inches of rain. The effect upon the vines was that they came out into leaf and that we had a very few grapes, none fit for market; I had one vine, however, which I watered, and upon that there was a very prolific crop, the grapes being of a very large size; my idea is, that if I could get sufficient water I could grow grapes to any extent. Advantages from irrigation.

4817. Have you tried the effect upon any other crops? Yes, I allowed the water to flow over some wheat land.

4818. Where did you get the water from? From the well; I got it up with a horse, and ran it over the land by gravitation, on a small patch of about 3 or 4 roods; I wished to try the effect; it does not answer when wheat is in the young stage; it causes the ground to crack; the soil opens, and if the sun comes out strongly the roots are destroyed; it will have a beneficial effect however when the wheat is in flower; when it is just coming into grain it will have the effect of filling the heads. Source of water. Time for irrigation.

4819. To what depth did you plough the land for the crops? With bullocks for 2 inches and with horses afterwards for 6 inches.

4820. If the ground had been trenched and ploughed 2 feet would the water have a better effect? Yes, because the subsoil would retain it longer. There are portions of land, however, which it would not do to plough to the depth you mention, on account of the clay which you would get about a foot or 18 inches down. Trenching and ploughing.

4821. But suppose you allowed the clay to mix with the top soil, would it not have a good effect? No; it cracks and runs together again.

4822. What would you be prepared to pay per acre for plenty of water for irrigation purposes? I could give you that information better when I discover what I am able to do with the well. I believe that if we had sufficient water we could grow potatoes twice a year. Water rate.

4823. What is your own idea of the value of irrigation per acre? I should say £1 an acre per annum for grass or crops.

4824. Is there no water to be had in Deep Creek higher up than your place? Yes.

4825. Could it not be conserved and brought down to your farm? Not in Deep Creek, but it could be done from Bullawaa Creek. The whole of the country on both sides could be irrigated. A great extent of water comes down from Bullawaa Creek in flood-time. There are bars running across the creek, and if you made some clay puddling the water might be raised to a much greater height than it is at present time. Water conservation on Deep and Bullawaa Creeks.

4826. Are there many farmers there? Yes, on all the creeks, and the result will be the same in each instance if they are all supplied with water. They would be in a position to increase their products tenfold. Farmers.

4827. You would be satisfied to pay a fair share towards the cost of irrigation? Of course the only thing we should have to consider would be how to find a market for our produce. When there is a good season here we have more produce than we can find sale for. Water rate. Market.

4828. Do you not think that the extension of the railways from this district westward would open up a large market for your produce? I think so, decidedly. I believe Narrabri is the furthest point west at which crops could be grown. The soil and climate are of a different nature down on the plains, and there is a terrible amount of evaporation.

4829. Do you think people in this neighbourhood would store up much of their crops against bad seasons? That all depends on their account at the bank. They may be compelled to sell at whatever price they can get. Storage of crops.

4830. But if they were not compelled to sell, and produce was at a low price, they would naturally store their produce for bad seasons? I think so. With reference to the evaporation which takes place on the plains, I may mention that when I was at the Government tank at Gallathra the drinking tank had about a foot of water in it. I made a little hole and wished to draw off the water for my own consumption. When I left the place one morning there were about 2 inches of water, and when I came back in the evening it had all dried up. The reason why I think that that was evaporation and not soakage was because on that night there was a thunder-storm, which I think was caused by the evaporation which had taken place. Evaporation.

4831. *Mr. M'Mordie.*] But it would not be surprising for 2 inches to percolate into the surrounding land, would it? It had had water standing on it for some time before; it was not as if the water had just been run on to it and could soak away.

4832. You had not made the channel between the holes on the same day? No; it had been made some time previously.

Mr. James Moseley called in and examined :—

Mr. J. Moseley. 12 May, 1885.

4833. *President.*] You have a station? Yes, Tibbereena.

4834. This is a considerable property I believe? Tibbereena is not a large property; but other properties which I have held and resided on for the past twenty-five to thirty years have been larger.

4835. Have you lived here for many years? About thirty.

4836. And you have a thorough knowledge of the district? Yes.

Dry seasons.

4837. You have witnessed a series of extremely dry seasons at various times? Yes; we had dry seasons in 1858 and 1862; there were also very dry seasons in 1866, 1868, and 1869; we were very fortunate then until about 1877 and 1878, when we had dry seasons. 1879 was the last wet season.

4838. Is this the longest series of dry seasons you recollect? It is not the most severe drought; we never had such a continuation of dry weather as we have had in the seasons from 1880 to 1885; we have never had the Namoi to its banks in those years.

Loss of stock.

4839. There has been a great loss of stock during that time? Yes, especially during the last two years.

4840. Has it been greater than has been known before? Undoubtedly; it has been caused by two things; there has been much more stock to die, and much more stock to eat the grass. I think that the deaths are about three or four to one in comparison with the numbers which have died in any previous drought.

Causes.

4841. Has this loss been occasioned in a great measure by the want of water or by the want of grass, or by both? No doubt both, for this reason,—that a great quantity of stock which would have just pulled through the drought weakened themselves by struggling in boggy land.

Irrigation.

4842. Has irrigation ever been attempted on a small scale by any residents with whom you are acquainted? Only on a small scale. I have irrigated about half an acre by means of a windmill.

4843. Do you raise the water from the river? Yes.

4844. Did you prepare the ground for irrigation? Only in a very rough way.

4845. You have never trenched it? The ground has been trenched, *i.e.*, dug to a depth of (say) 2 feet, as for trees, &c., but not trenched properly as for irrigation.

4846. From your small experience did you demonstrate that the use of water would make the land productive? Undoubtedly. The Chinese garden over the creek is an instance of what may be done by irrigation, and of course they only use hand labour, although they irrigate thoroughly.

4847. Without irrigation the plot of which you speak would not produce anything? It would not have produced a cucumber in the last three years.

Available agricultural land.

4848. What is the extent of land available for agriculture in the valley of the Namoi as far as Gunnedah, or any other point which you like to name? I should think you could safely reckon on an average of about 50 to 60 miles in length; the average width would be about 10 miles, that is between here and Gunnedah on the north side; by clearing scrub you might get as much again.

4849. Do you know the country above, at the head of Breeza Plain, up the Mooki? Yes.

4850. What distance from Gunnedah would that be? About 50 miles up to the heads of the Mooki and other streams forming tributaries to Namoi from that watershed, though much more to any of the other heads of the Namoi, *i.e.*, Namoi, Manilla, Macdonald, Peel, &c.

4851. Is it level country? In the train you run right along the plains until you get past the Willow-tree.

4852. What is the average width of that country? It is enormous; you take all the heads of the Mooki; the average on both sides would be 25 or 30 miles by about 40 in length, *i.e.*, say 10 to 15 miles wide on each side, from Breeza upwards. In some places you would get half-way to Bando before the fall comes in. Cox's Creek would be just the same.

4853. Then we have blocks 50 by 25 miles above Gunnedah, and 60 by 10 miles below Gunnedah? Yes.

Results from impounding water.

4854. Suppose it were possible to impound a large quantity of water on the different rivers in such a way as to get to the plains, do you think that the whole of that country could be governed by a system of irrigation? It would be difficult to say. I should imagine that a large proportion of it might be. A large area of this country might, owing to the irregularity of ground in elevation &c., be unfit to irrigate.

The Mooki.

4855. Where does the Mooki discharge? Into the Namoi, just above Gunnedah.

4856. Is it a flat creek? It comes down right through the plains; that is, flat while crossing the plains.

Nandewar.

4857. Have you an intimate knowledge of the Nandewar range near Narrabri? Yes.

Basins.

4858. Do you think that there are large basins there which could be utilized for the storage of water? I showed one place to Mr. Gipps at the head of Spring Creek; you would require about a mile of a dam there; this extent is only as guessed by Mr. Gipps and myself, and is across from spur to spur.

4859. What area of land would that cover above the dam if the dam were (say) 50 feet in height? Mr. Gipps ought to be able to tell you, as he had a good look at the place; it would run on an average about a mile in width, and it would be about 3 miles long I should say.

4860. And if the water were impounded at that point, it would be at an elevation commanding the whole of the good land between there and Narrabri? Yes.

The Gulf

4861. Do you know of any other places? Yes, there is a much better place called the Gulf. As far as I can judge it is a much larger basin, and the dam would only require to be a few yards, probably 200 to 300 yards, instead of a mile long; I think that the place is well worth examination; water impounded there would also command the lower country; all the water goes down to Bourke.

The Rock.

4862. You are acquainted with a place in the neighbourhood of and above Boggabri, called the Rock? Yes.

4863. Is there a ridge coming down to the river on the southern side? Yes; this ridge is about half a mile below the Rock, known as Biddy-wyndia.

4864. Is there a corresponding ridge of country coming down opposite on the north side? No, I think not; the ridge comes down on the north side, about half a mile below the Rock; the ridges on north and south sides of Namoi, below the Rock, are nearly opposite.

Country about The Rock.

4865. The country in this neighbourhood is flat, and the plains extend out some distance from the river? Not immediately from the Rock; about there it is precipitous. From Gunnedah, where the Mooki joins, to Narrabri, the Namoi is confined; you get small plains, but not of any extent; parts of Burburgate are pretty level, but you can see the mountains or ridges a few miles from the river, all along the same.

4866. Is there a bar of rock at this point? Of no great extent; I only judge from casual observation; it is much similar to that seen by the Commission immediately above Tittamuch Rocky Crossing.

Bar at Broadwater.

4867. Is there any point in the river, from that point downwards, at which rocks can be found? The next bar is at Broadwater; Mr. Gipps inspected this.

4868.

Mr. J. Moseley.

12 May, 1885.

4868. Is that near the Turrawan waterhole? That would be the place; there is a small bar about 3 miles above Narrabri.

4869. Do you think that it would be possible to throw across the river, at any of these bars, weirs which would be likely to stand? You might possibly do what you require by means of overshot dams, but that is a part of the question which is beyond my knowledge.

Overshot dams.

4870. Supposing that the water were thrown back by means of overshot dams, would that tend to divert the channel of the river in any way? I doubt it; the upper current in times of flood is strongest.

4871. Do you think the nature of the banks is such that if the water ran over them at all it would be inclined to make a wash? It would if you confined it about here, but lower down the river I do not think so; lower down we find that the bed is the smallest part of the stream in a flood; the river in floods running out into warrambools, billabongs, &c.

4872. Would the construction of overshot dams at this point have the effect of throwing a reach of water back any distance? I can hardly say, but I should think not of the extent you would require.

Importance of navigation.

4873. Do you consider that the damming of the river, at various points where facilities offered, would be disadvantageous if a railway were run in the vicinity of the river: would you consider the navigation of the river of more importance than the impounding of water under such circumstances? Certainly not; that is if the railway afforded the same facilities and rates of carriage as the river would do.

Utilization of stored waters.

4874. Do you think that if large quantities of water were stored, and placed within reach of persons resident in the district, coming down from the hills by means of gravitation, or from overshot dams on the rivers, that the water would be used to any great extent? We should have to have considerable population; of course it is done in other parts of the world, and I see no reason why it should not be done here; I have seen similar works in California, and I have read of such in Italy; I do not think that it would pay for grazing.

Storage of produce.

4875. But if the squatters had an opportunity to obtain water in this way, do you think they would be likely to grow a large quantity of produce to store for stock in dry seasons? That is a very difficult matter on which to give an opinion; the only way in which you could make them do so would be to carry produce at a higher rate by rail; produce at present being as a rule much more cheaply procured from the Hunter and Paterson, &c., than it can be cultivated hereabouts at remunerative prices to farmers.

4876. Suppose produce were at such a high price in the upper parts of the hilly country that it would not pay to purchase it to feed stock in dry seasons, do you think that under these circumstances the lessees would be inclined to utilize the water and grow produce in reserve? I can hardly say; I know that it has been done. In California a comparative desert with a population of about one man to the square mile has been converted into a place in which there is now a population of two men to the acre.*

Water rate.

4877. Do you think that the farmers or selectors in this district would utilize the water and be prepared to pay a fair rate for it? Farming is now a dead letter; they cannot compete with the down countrymen. If there were a change of season it might be different; now they cannot compete with the Maitland and Clarence men.

The farmers.

4878. Their only opportunity of competition lies in the presence of water? There is no doubt of it; the farmers are now existing—they are not living; they live chiefly by wool-carrying, and by doing a little fencing and shearing now and again.

Crown Lands.

4879. If water were impounded and were available for irrigation, is there any large area of Crown Land open for selection below Narrabri upon which that water would be likely to be utilized? Yes, large areas from Narrabri to the Barwon, and on the other side of the Barwon there is no selection to speak of.

Subdivision of properties.

4880. Do you think that persons possessing large properties would be likely to subdivide them and let the land for farming purposes if there were a good supply of water, and if they found that it was likely to pay them better than keeping the land for the purpose for which it is used at present? No doubt of it; we certainly cannot make 5s. per acre on grazing land now, and of course if we could let the land to farmers at £1 per acre we should be quite prepared to do so.

Wells.

4881. Have you any experience in well-sinking? Not here; I have done a great deal.

4882. In this district? Yes; from here towards Edgeroi and Gurley. The depths are very uncertain; you get water in some places at from 10 to 20 feet, and in other places you cannot get it at 120 feet. The basalt crops up through the ground lower down. On the north side of the river towares Boolcarroll there is a uniform depth; from Gundamine towards Boolcarroll water is obtained at a uniform depth of about 80 feet.

Boolcaroll.

Stratum.

4883. Is that all one stratum then? Evidently so; you go down through ordinary black soil on the plains, then there is a sort of fine sand, after which you reach the river gravel, and when you have taken out a certain amount of gravel you get a rapid flow of water.

4884. Do you put down cylinders? I have never known of cylinders being used.

Source.

4885. Have you any idea of the source of the water? I imagine that it has originally been the bed of this or of some other large river; it is exactly the same gravel as you find in the river bed at the present day.

Area.

4886. What width would that area be? More than 30 miles long, and about 12 wide.

Old watercourse.

4887. Apparently it is an underground watercourse? I should say so.

Supply.

4888. Have you noticed the water flowing in any direction? I have not noticed it. We have drawn for two days and three nights at the rate of about 60 gallons per minute from a well which is 7 feet by 4 feet clear, and of a depth of 70 feet. Of course there was a little loss of time in changing horses in the whim, but we have never been able to decrease the water in that time and at that rate of work.

4889. That would be about 216,000 gallons in the time you have stated? Yes, that would be the amount if the work never ceased and there was no loss of time. I do not suppose that we ever quite drew that quantity. In dry weather sometimes there is a loss of a few inches.

4890. Do you know of any other part of the country in which the same thing occurs? No.

4891. Would it not lead you to suppose that there is a line of water running underground from the Namoi towards the Barwon? That is one theory.

4892. It could not be water from the Barwon to the Namoi? No; not unless the Barwon be a higher level than the Namoi.

Wells on Thalaba Creek.

4893. All the wells on Thalaba Creek are deep, with little or no water? Some selectors named Burrowes have some good wells near the creek; they are very deep, and they are sunk through salt. I have heard of, but have not seen these wells.

4894.

* Note (*on revision*):—This is what is stated in California. I cannot vouch for the figures.—J.M.

Mr. J. Moseley. 12 May, 1885.

4894. Does this water run from the Namoi to Thalaba Creek? I should not think so.

4895. Do the banks erode on one side by the force of the current when the river is running in flood and deposit on the other side? Not to any perceptible extent; little spits are being constantly formed.

Erosion. 4896. You do not remember the course of the stream changing very much? No; the river in the past thirty years has made small deviations in the ana-branches and bights, but not to any very great extent.

Artesian water. 4897. **Is the water artesian in any of the wells of which you have spoken? It does not rise to any great extent; but we have not got to the proper depth; we have only used pick and shovel.**

Trusts. 4898. Do you think that if any system of water conservation and distribution were adopted, the best plan would be to form local Trusts throughout the Colony? I can hardly say.

Silt. 4899. *Mr. Franklin.*] You have not had an opportunity of disturbing silt in the bed of the river in dry seasons? We have had to do it on several occasions; I am doing it at the present time in the creek which runs into the river.

4900. Are you actually doing so in the bed of the river? I have done so to obtain water in former droughts, but not now.

4901. Do you find the water there at a corresponding level to the ridges above and below? I should say probably so, as they have been drunk up by stock to the lower level, so I have had to deepen the well in the bed of the river.

Level. 4902. You think that the level is continuous throughout the river bed? Yes; some beds of clay may throw it higher up here and lower down there. All down the Namoi they have been able to get water in times of extreme drought. In 1838–9 they were always able to get water by digging a certain depth in the river.

Deposits. 4903. Have you observed great changes in the deposit of silt after floods? Yes, there are great changes all along the river; I can show you three-quarters of a mile where the river is dying away.

Water reaches. 4904. Has a long reach of water been known to exist through all changes of season for many years? That at Broadwater is one, and another above Boggabri, known as "Bool."

4905. Have you ever known it to be silted up? No.

Deposits. 4906. Would the large deposits of silt of which you have spoken be in the vicinity of the discharge of creeks from the mountain sides? The one which I spoke of is near the mouth of a sandy creek called Jack's Creek.

Sand. 4907. Do you suppose that the sand is brought in by the creeks from the adjacent mountains? Yes.

Water conservation. 4908. *Mr. Murray.*] As a practical man of long experience in this district, you have come to the conclusion that it is quite practicable to conserve water for the benefit of the whole district? I have no doubt of it.

4909. And that it would increase the productiveness of the place and enhance the value of the country very much? Yes.

4910. And that the people would contribute a fair amount towards the interest on the money expended upon the necessary works? I should think they would; certainly they ought to do so.

4911. *Mr. Franklin.*] Do you know the course of the river from the junction of the Manilla? Yes.

Channel. 4912. If we were to cut a channel down the best course on the northern side, what length would it be? Something over 100 miles I should say.

4913. What is the river course? I can only roughly estimate it at 2 to 1.

Mr. William Pirie called in and examined:—

Mr. W. Pirie. 12 May, 1885.

4914. *President.*] Where do you reside? Tarriaro, about 9 miles from here above Narrabri.

4915. Have you lived here for many years? About twelve.

Irrigation. 4916. Have you adopted any system of irrigation for gardens? I have water laid on for the garden, but it is raised by a small horse-pump.

4917. But you have demonstrated the necessity of having water in that way in order to grow anything? There is no doubt of it.

4918. Did you prepare the land by trenching? For some purposes I trenched it, but for others I did not; I have not trenched it for grapes—they do remarkably well without trenching.

Agricultural land. 4919. Do you think that there is any large extent of land in this district which would be utilized for agriculture if there were plenty of water? There is a great deal of land upon which you could grow almost anything, especially wheat and grapes.

Crops. 4920. One witness whom we have examined said that if he had plenty of water he could grow two crops of potatoes from the same land in the year? If so, he is right. That is done, and it could be done easily if there were plenty of water at command.

The Rock. 4921. Do you know a place called the Rock? Very well.

4922. There is a ridge coming down to the river on the south side? Yes.

4923. Is there any high country on the opposite side? Yes, but considerably lower down—quite a mile.

4924. You are sure that there is a difference of about a mile between the rock on the south side and the high country on the other side? Yes, I believe it is about a mile.

Dam. 4925. And a dam would have to extend the whole distance? Yes; there is nothing which a dam could abut on to nearer than a mile.

4926. Suppose a dam 50 feet high were constructed, would a large quantity of water be backed up there? A very large area.

4927. What width would the water extend over the plains? I should think about ¾ of a mile.

4928. About what distance from the dam would the flat country be opened up? About a mile above the north side.

4929. And it would continue to be opened up on the north side? Yes.

4930. Until it got how wide? For 4 or 5 miles up* (say) it would be 10 or 12 miles wide.

4931. Would a 50-feet dam raise the water up to that point? Scarcely; I think that it would very nearly do so; the general fall of the river there is about 16 feet to the mile.

Fall of river.

4932.

---

* NOTE (*on revision*)—Down, I mean to say. I mean that 4 or 5 miles down the river from a dam thrown across at the Rock the flat country would open up to 10 or 12 miles wide on both sides. Above the Rock there is a large area of flat land which could be irrigated, but the water would have to be taken out of the river much higher up.—W.P.

4932. Supposing that a large quantity of water could be stored there, would it command any great extent of land below? Not such a great deal of plain land immediately below. Mr. W. Pirie. 12 May, 1885.
4933. Could the water be drawn off by means of a canal on to a large extent of country? Not without carrying the canal down near to the river for some 3 or 4 miles. Canal.
4934. If the water were drawn below at an elevation by means of a canal, it would command a width of 10 or 12 miles of good land, mostly on the north side? Yes.
4935. Have you any knowledge of the hills at the back of your property? Yes.
4936. Have you noticed any places at which large quantities of water might be stored at the mouths of the creeks? Several places in the Nandewar range. Storage.
4937. Are they worthy of examination by our Engineer? I think so.
4938. Can you give us any accurate description of them? No. Eulah, Bullawaa, Maule's and Bibla Creeks have in certain places to pass through very narrow gorges.
4939. Have you sunk any wells on your station? Yes. Wells.
4940. With what result? Plenty of fresh water.
4941. No artesian water? Some of the water rose 30 to 60 feet. Rise.
4942. Is it drainage from the Nandewar range or from the river? I think from the range; it is an underground supply of water coming down towards the river; we often get it through beds of pebbles set in clay; it is a clay-pan full of water-worn pebbles. Drainage. Underground supply.
4943. Have they been brought down from the hills? I think that they must have been rolled down the mountains and bedded in what must have been at one time a very large basin. I do not think that it is water from the Namoi.
4944. Have you noticed that the river water is lost at any particular point by percolation? Yes. Percolation.
4945. Can you fix any point? There are half a dozen places between here and my place where water disappears and reappears.
4946. It goes below sand? Yes.
4947. Do you know of any place where water goes away from the river altogether, and in which the volume of the river is lessened and does not return? No.
4948. Have you ever tried if there is a current in any of these reaches? I have often sunk small holes in the river, and I have found that the water runs into the bed. Current.
4949. Have you ever noticed in any of the long reaches any floating bodies which would indicate that there was a current? I do not think I ever noticed any.
4950. Is it your impression that the water is flowing down the river? I think that there cannot be any doubt about it.
4951. *Mr. Franklin.*] Are the banks usually above the highest flood known, that is the natural banks? No. Banks.
4952. At the Rock what is the width of the river at the highest flood? I should think about a mile and a quarter on the northern side; opposite, the width would be about half a mile; during high floods there is a large sheet of water 5 miles up the river, about 300 feet wide. There is a sheet of water called Broadwater, extending for about 5 miles on the river, which at high floods extends over the banks to about 2 to 3 miles in width; it is situated about 10 miles above Narrabri; a weir raised above the level of the banks would hold a large supply of water. The width of Broadwater ordinarily is about 300 feet all the way up. Floods. The Broadwater.
4953. Is it your opinion that it would be practicable to throw overshot dams across the river at certain selected points which would be likely to stand? I believe it would, but I think that it would be very costly; I think that in many cases the banks would wash away; the banks are invariably soft on one side and hard on the other. Overshot dams. Banks.
4954. But with judgment in the selection of the sites you think that the work could be carried out? I think it might be done in several places; at Broadwater I suppose that the hole is about 20 feet deep in places, and to raise a dam to the top of the banks you would have to raise a bank about 20 feet higher than the bed—or taking a bar from base of embankment, somewhat less.
4955. Have you ever had occasion to construct any jetty or timber works in the river? I have put up a wattle fence when the river was dry; the posts are still standing—they have been standing for the last seven years. Jetty.
4956. Is there any scour in the banks near them? No, but there is a scour around the roots of trees, especially in cases where trees have fallen and the water gets between them and the banks; in one place, at Tarriaro, the bank has washed away 8 or 10 feet in twelve years; it is about 20 feet deep. Scour.
4957. You have seen large floods? Two or three.
4958. Have you had large deposits of sand on your land? Yes.
4959. On the surface? Yes, it has been left in the bends a great deal. Deposits.

SATURDAY, 16 *MAY*, 1885.

At Walgett.

Present:—

MR. DONKIN, J.P., | MR. FRANKLIN, C.E.,

MR. M'MORDIE, M.I.C.E.

F. A. FRANKLIN, ESQ., C.E., IN THE CHAIR.

Mr. Frederick York Wolseley called in and examined:—

4960. *Chairman.*] You are a run-holder in this district? Yes; I have Euroka. Mr. F. Y. Wolseley.
4961. How is that situated with regard to Walgett? The run commences four and a quarter miles below Walgett on the south side of the Barwon River; it is in the county of Leichhardt.
4962. I suppose you are well acquainted with the district generally? Fairly; not with the outlying portions to any great extent. 16 May, 1885.
4963. What is the state of the Barwon at the present time? It is flowing slowly. The Barwon.
4964. And in its course is the water continuous, or is it interrupted by silt? It is continuous.
4965. It is a continuous stream? From here to Brewarrina; there it is interrupted by rocks.
4966. And I suppose you consider this a very dry season? Yes.

Mr. F. Y. Wolseley. 16 May, 1885.

4967. Have you ever known the Barwon to be completely dry? Never.
4968. How many years have you been resident here? Nine years.
4969. I suppose you consider the present time is the continuation of an unusual drought? Yes, almost unprecedented.

Loss of stock.

4970. And there has been a very considerable loss of stock throughout the district? The losses have been very numerous.
4971. Could you roughly estimate the extent of the loss with regard to the total stocking of any portion of the country within a considerable radius of this place—taking (say) a radius of 100 miles from Walgett? I should think 60 per cent.
4972. Could you give in an approximate estimate of the quantity of stock in that area? No, I could not. Some stations I may say have lost all, some one-half, and some have lost comparatively few.

Causes.

4973. I suppose the majority of losses were occasioned entirely by the want of feed? Yes.
4974. In no measure from the want of water? Not to my knowledge. Of course want of water has had a great deal to do with it. Had there been more water probably the losses would have been less, because many of the stock died from bogging, owing to the lowness of the water.
4975. In estimating the quantity of stock within a radius of 100 miles you necessarily go beyond the distance from which you could bring stock to the river—you could not bring stock 100 miles to water? Of course not.

Creeks.

4976. Then are there any creeks between Walgett as a centre and that radius of 100 miles in which there is a constant supply of water? No creeks or rivers except the Barwon are constant in their stream.
4977. And how do you manage to water stock at the outer part of the radius? By conserving water in tanks.

Dams.

4978. Do you know if any effort has been made to store water in dams along the creeks which are running from the river? Very few efforts to my knowledge, because of the uncertainty of tenure.

Reservoirs.

4979. What would be the result if you were to make large reservoirs for the storage of water in the creeks? By conserving water liberally, the general management of stock would be materially assisted.
4980. What would be the result to the runholders if they were to make large reservoirs of water between the rivers so that the flood-waters could be impounded? The stock could be kept generally in better condition, and naturally there would be more wool.

Uncertainty of tenure.

4981. Then why is it that a more general effort has not been made to conserve water in that manner? On account of the uncertainty of tenure—the want of security to the runholder who would incur the expense of making the provision. There is no guarantee, no protection of any kind to the person who incurs the outlay. He may spend his capital freely in endeavours to store water, and shortly afterwards find his efforts frustrated by another depriving him of the benefit he had hoped to obtain.

Reserves.

4982. If he were protected by a reserve for a considerable area in the neighbourhood of these improvements, would he be induced to do more than has been done in the way of water conservation? Very much more.
4983. Could you give me any idea upon what terms such reserves for your protection could be established? I should say that, in the case of dams, were the land on both sides of any creek—say to the extent of 2 miles back—protected to the lessee, he then would be prepared to invest largely in the construction of dams for the conservation of water.

Stock-routes.

4984. And as that reserve would in many cases cross runs, would there be any objection to make the stock-routes along that water-line? Certainly.
4985. What would be the objection? It would deprive the lessee of the run entirely of the advantage of the water; it would, in fact, be opening the run to the general public.
4986. So that the advantages of the water to you would be entirely nullified? Entirely.

Depressions.

4987. Do you know of any tributaries to the Barwon and Namoi where there are large depressions in which water might be stored? There are very many such, and water could be stored largely if the lessee had any security for his investment.

Cost of water conservation.

4988. Taking an ordinary run in this part of the country, what would be the cost of water conservation in proportion to the general expenses of station management? You cannot calculate it annually, because before you stock country you must conserve the water, and that conservation must depend on the quality of the country. There is afterwards the annual expenditure to keep the tanks in repair.
4989. What proportion would the expenses bear to the other expenses of securing the property by fencing and other improvements? Conservation of water would be the greatest expense.

Water rate.

4990. Supposing a system of constant water supply to pastoral tenants could be established at a moderate cost, would there be any objection on the part of runholders to pay for that constant supply? None, if the water were conserved in such a way that it would not interfere with the rights of the lessee; the lessee would then be perfectly willing, as far as my experience goes. I am personally inclined to pay a portion of the expenses, of the interest, on any money which may be expended in the conservation of water.
4991. You are of opinion that if water could be conveyed through this dry country, and placed under Trusts or some other means of local supervision which might be devised, the lessees would not object to pay a fair interest on the outlay? I think not, always provided that they knew beforehand that they would be secured on the leasehold of the runs. At the present time there is really no security. Now you may invest private capital in developing the resources of the country to the extent of thousands of pounds, and you have no guarantee that you will be able to call the improvements your own.

Security of tenure.

4992. From that I infer that under a more secure tenure you would use still greater exertions to avoid the disastrous effects of these great droughts? I have no doubt in my own mind that if protection were afforded, the money expended in the conservation of water could be increased 300 or 400 per cent.
4993. What system do you now adopt for watering your run? It is watered on the front by the Barwon River, and on the back by tanks.

Tanks.

4994. How do you construct tanks in this flat country in order to obtain a sufficient watershed for their supply? I have excavated them at the edges of the few natural rises or low salt-bush ridges.
4995. Do you adopt any system of survey before you fix a site for a tank? No; I simply fix the tank where I know the water will run off the ridges, and by means of drains from the small ridges I convey the water into the tanks.

Capacity.

4996. What is the ordinary capacity of your tanks? From 4,000 to 10,000 yards.

4997. In what shape? Square; I mean, of course, that the excavation would be square.
4998. Are your tanks sunk under contract? Always.
4999. And they are constructed to your satisfaction? Yes.
5000. In specifying for the construction of tanks, do you specify that the slope shall be perfect—that the angles shall be taken out accurately? It is not absolutely necessary.
5001. Would that increase the cost? Yes, it would be greatly increased if you made the work so very accurate; we do not consider it necessary.
5002. How is the earth excavated? Generally by plough and scoop and pick and shovel. Some adopt one system, some others; it is entirely within the choice of the contractor. (*Appendix* W.)
5003. What is the batter of the sides, excepting the slope for the watering of the cattle? Tanks are generally constructed with a batter of from 3 to 5 to 1, with 6 to 1 for the roadway; thus stock can water all round. I do not approve of stock watering at tanks at all; that is to say, I do not approve of their going direct to the tank.
5004. Have you adopted any measure which you have found to be superior? Yes, I have; it is only when the stock water at the tanks that I make the batter 5 to 1.
5005. You pump from the tanks? Yes.
5006. In pumping from the tanks, what manner of distribution do you use? I have raised tanks 6 feet above the surface of the ground.
5007. And in so doing you have adopted the general system of the district? Yes.
5008. How is that tank constructed? With wood, lined with sheet-iron.
5009. And you distribute the water from this tank into troughs? Yes, by means of a ball and valve.
5010. That system of tanks requires constant supervision? Yes, to keep the supply tanks full.
5011. So that the cost of the supervision is added to what you say is the proportionate expenditure on the run for water conservation? Yes.
5012. If a system of constant supply could be established, it would very much reduce your general expenditure on the whole of the run for a period of ten years, and you think it would receive your support? Certainly.
5013. You know the Government tanks? I have seen them.
5014. The description you have given of a tank on a small scale is much like the system adopted by the Government? Something similar, but their arrangements are more elaborate and better.
5015. And in as many cases as you have seen you consider them satisfactory? Yes.
5016. And you do not know of any other method which has been applied in this district and which you consider more practicable? None, except as I before stated, by the construction of dams, were security afforded for the outlay.
5017. Do you apply any of the water which you now conserve to agriculture? None.
5018. If you had abundance of water, would it be worth your while to cultivate paddocks if you could convey the water by gravitation? If I had security of tenure it might.
5019. If you could command an area of (say) 200 or 300 acres, would the soil be suited to agriculture? It would grow anything suitable to the climate.
5020. Supposing you had an abundance of water, and this water could be made to produce feed for your cattle, would you be inclined to cultivate a large area in order to store feed against bad seasons? No; because the expense of cultivating crops to keep your cattle alive would more than equal if it would not exceed the value of the stock in the course of a very few months.
5021. Is that the general impression? I believe it is.
5022. You are aware that it is practicable and that it has been proved that cattle can be saved by feed stored in that way? I do not think it is done in this district. I have no doubt that it can be done on a small scale, and that you could keep a small number of cattle alive; but in this district the runs are nearly all stocked with sheep—there are very few cattle; and in speaking of the production of artificial grasses I must be understood to refer to sheep—not to cattle. The quantity required to protect yourself against drought in order to save your stock would be too great.
5023. I am not speaking so much of artificial grasses as of the growth of cereals and hay? That would be the same; the expense of producing the hay would be greater than the value of the stock, even if you had to keep them alive for twelve months, unless of course you applied it to a limited number of selected sheep.
5024. Supposing it were not possible to grow sufficient fodder for all your stock, would not a certain supply tide you over the most disastrous period of a drought? I do not think it would pay under any circumstances. I do not know of any principle upon which you could produce the fodder so that it would pay, if you had a sufficient quantity of water.
5025. The labour would cost more than the absolute loss of stock, of which you have already spoken in your evidence? Yes; I think the effort to keep the stock alive would cost more than they were worth. It would be economy to lose your stock in preference to going to the expense of raising fodder to keep them alive.
5026. Can you give the Commission any idea of an arrangement which would secure you against the effects of these droughts? No; you cannot fight against the freaks of Nature. The only preventive in the case of emergency, I should say, would lie in the extra conservation of water. I know of no principle upon which you can profitably produce fodder for stock.
5027. Has any attempt been made to hold back the waters of the Namoi River by means of dams? Not that I know of.
5028. Not in a small way? No.
5029. So that you do not know what the result of that would be? I know of small dams which have been erected when the river had almost ceased to flow, but they were only temporary dams.
5030. Was the flow apparent? Yes.
5031. What was the height? 4 feet.
5032. How were the dams constructed? With plain earthwork.
5033. And it was expected that they would be carried away at the time of a fresh? Yes.
5034. What was the result? The water backed up behind the dams. I know of one dam where the water backed up 4 miles.
5035. How is that water made available for stock or other purposes? It was not brought to the surface—the stock were watered at the edge of the water.

Mr. F. Y. Wolseley.

Results.

Mr. F. Y. Wolseley.

16 May, 1885.

5036. In a small way it proved practicable for the retention of water on the banks of the river? Yes. There is no doubt that dams could be constructed and would be constructed on a very large scale if the lessee were protected in the expense he might incur.

5037. Have you seen the Namoi and Barwon in flood? Yes.

Floods.

5038. Have you any idea of the velocity of the stream in flood-time? About 5 miles an hour.

Velocity.

5039. That is in the centre of the current? Yes.

Width.

5040. What is the average width at high flood? In a very high flood it extends from the Barwon to the Castlereagh. In 1876 it extended, to my knowledge, 10 miles back from the Barwon.

Discharge.

5041. In your opinion, the whole of the water discharged passed Bourke to the Darling? I should think so, as all the minor rivers and creeks eventually empty their waters into the Darling.

5042. For how long a period does that extent of water remain on the country? The country is so flat that in the year 1880 the water remained for one month stagnant.

5043. Over the whole surface of the country? No, only over some flat-lying strips.

Waterholes.

5044. And when it subsided into the creeks were they flooded for any length of time? No; because the creeks gradually flow out into the river—the creeks become chains of waterholes.

Locks.

5045. No effort or suggestion had been made to lock the entrance of these creeks so as to hold the water? None that I know of.

5046. Would it not be an advantage to you to have the creeks constantly charged? Yes. Private enterprise would do all that is necessary if we had security of tenure.

5047. As far as you know this radius of 100 miles, do you think it would be possible to lock the flood-waters in these watercourses and billabongs? Decidedly.

5048. Under a proper tenure, if such a work were suggested, there would be no objection to pay for the advantages derived from such a storage of water? None.

Wells.

5049. Have you done much in the way of water supply by wells? I have tried on my run thirteen bores. I used Pierce's machine.

Depth.

5050. What was the result of those bores? I found water at depths varying from 40 to 68 feet.

Supply.

5051. In any quantity? Apparently a large supply.

Quantity.

5052. What was the nature of the water? In every instance the water was brackish. I had the water analyzed by a chemist in Sydney, and the analysis proved that the water contained more salt in solution than the sea does. It was unfit for stock, as being of a poisonous nature.

Earth.

5053. Did you send samples of the earth at the level at which you found the water? No, I only sent the water.

5054. Then the earth has not been analyzed? No. I know that it contains a very large proportion of soda—it is visible to the naked eye.

Supply.

5055. Did you attempt to go below that level? No. The supply of water was very great, and it rose in the bore.

Artesian.

5056. It was artesian? To a certain extent. It rose 15 feet—I found it in coarse drift.

Country.

5057. What was the nature of the country where these bores were made? All flat, black-soil country.

Test bores.

5058. In making those test bores, did you go any great distance apart to get away from the basin of salt? I separated them by 5, 10, and 13 miles. I tried in every eligible spot, and in every case I met with the same result. Eventually I gave it up in despair.

Expense.

5059. I suppose you have made a large expenditure on these test bores? Yes, very large.

5060. Do you know of any one in your neighbourhood who has been more successful in sinking for water? I do not.

5061. At what distance would you say from your run, taking a certain radius, have they failed to get water by means of wells? I know they tried at Wingadee, and with similar results.

Depth.

5062. You have not heard of their having gone to greater depths, going through the salt water and afterwards striking fresh water? Not in this immediate neighbourhood. I have heard of wells being sunk 200 feet with results similar to my own.

5063. In this neighbourhood? Yes.

Surface water.

5064. Altogether you think that the surface water is to be depended on in the vicinity of Walgett? That is my experience.

5065. The water does suffer from saline matter on the surface? It does to some extent. When tanks get low the water becomes brackish to a certain degree, but not in any way to injure it.

Evaporation.

5066. Have you remarked the proportion of evaporation in regard to consumption in your tanks? I have never made any calculations, but I may say that the evaporation in the exposed tanks is very great in windy weather.

Tanks.

5067. Did you arrange the materials taken from the tanks in such a manner as to protect the water from these strong winds? Not with the object of protecting the tanks. I generally bank the earth around the tanks, and that in a great measure does protect them.

Wind.

5068. Is it a prevailing or a chance wind? A chance wind.

5069. Not more from the west than from any other quarter? No. I do not think the evaporation is directly caused by the wind; it is by the absorption and constant evaporation from the soil, owing to the wind blowing the water on to the slope.

Plants.

5070. You never made any attempt to plant round the tanks, to prevent absorption by windage? No; the plants would absorb more water than would compensate for the advantage which you would gain from their being there.

Suggestions on water conservation.

5071. Could you give us any general information or make any suggestion which you think would be of service to the Commission? The only suggestion I would make would be this,—that if greater protection were afforded to the capitalist a very much larger amount of money would be invested in the conservation of water. I believe that private enterprise would then benefit the district immensely. Under the existing tenure of our runs we have no protection; therefore we merely conserve that water which is sufficient for the day.

5072. *Mr. M'Mordie.*] You say that if water frontages extending 2 miles back from the creeks were granted to the runholders, works of water conservation would be carried out by them? Yes.

5073. But would not that give them a monopoly of the land in such places, and tend to prevent settlement in the neighbourhood? That is a question I cannot consider; I merely answer the question put to me as to how it would be possible for water to be generally conserved for the benefit of the runholder; if they were called on to conserve water they would naturally expect some protection.

Mr. F. Y. Wolseley.

16 May, 1885.

5074. Are you aware that in some districts of the Colony crops are grown by means of irrigation, and that these crops are the means of saving large numbers of sheep and other live stock in time of drought? I never heard of one instance.

Irrigation.

5075. Are you aware that some very large runholders have purchased great quantities of hay for the feed of stock at critical times, at prices far beyond the cost of growing it by means of irrigation? I heard of their doing that in the Murrumbidgee district to save their stud sheep, but I do not think it has been done in this district.

Farming

5076. When water is available for pumping, what would be the cost of growing wheat by means of irrigation? I know nothing of agricultural farming, but I should imagine that farming could be conducted by these artificial means only on a very limited scale; it takes a very large quantity of water to irrigate this soil; it is very porous and very deep, and in almost every place it would take a very large volume of water.

Well at Goodooga.

5077. *Mr. Donkin.*] You say you do not know of any payable wells being sunk in the district within 100 miles: do you know that the Government has struck water at Goodooga, and that the bore produced 48,000 gallons per day? I am not aware of that.

5078. Goodooga, I believe, is 100 miles from here? About that.

5079. Is it the same sort of country? Similar country.

5080. According to Mr. Henderson's report it is an inexhaustible supply? I have not heard of it.

Sheep and cattle stations.

5081. You said that nearly all the stations about here were sheep stations: are there no cattle stations left in the district? I do not know of any in the immediate neighbourhood.

5082. Can you assign any reason for it? Only that sheep are more profitable.

5083. And do sheep stand the drought better? Yes; they can live on scantier herbage.

5084. I think you have had experience in the Riverina? Yes.

Wells in Riverina.

5085. Did you find some difficulty there in consequence of chemical matter in the water? No; wherever I sank wells in the Riverina I have found water suitable for stock, that is between the Murray and the Edward Rivers.

5086. Have you had experience in Queensland? Lately.

Water in Queensland.

5087. Is there the same difficulty in obtaining water there? The difficulties are greater there, because rock is encountered at from 2 to 5 feet from the surface; that is between the Warrego and the Nebine Creeks.

Supply.

5088. Did you obtain water for stock? Not enough for stock purposes; the supply at the shallow depth —40 feet—was limited; that gave me the belief that the water was not a spring but a soakage; I believe that water would be obtained by sinking deeper; the first indications were certainly sufficient to warrant such deeper sinking.

5089. How far from the Barwon would that be? About 300 miles.

Fodder growing.

5090. I understood you to say that you do not think it would be a commercial success to grow fodder for feeding stock in the time of drought? I do not.

5091. What do you consider the average return per sheep per annum? That depends very much on the season.

Return from sheep.

5092. Supposing you could keep them on artificial feed in times of drought, what return would you look for? I should be satisfied with from 4s. to 5s. per head.

5093. Did you get that this season? No; there was a loss of about 10s., I should think.

Well-boring Hand labour.

5094. You spoke of your using Pierce's well-borer: did you employ hand labour or horse-power?

Tubing

5095. You have not tried tubing in the wells which you have put down? No.

5096. Do you know that Pierce's Company say that it is absolutely essential to tube the wells in order to obtain water? I came on to drift in every instance; I had no tubes, therefore I could not go through it.

5097. Do you know that Mr. Darley, in his report upon wells in America, specially points out that the secret of obtaining water in most wells consists in the use of tubes? It may be so; I have not tried it. The expense would be rather too great for trials. Here the country has not been tested, so you would not know to what depth it would be necessary to obtain tubes for; the expense would be too great.

5098. You have no means of carriage here except by teams? No; it is by teams.

5099. Do you get water carriage to Walgett? The river has not been navigable since 1876.

5100. Do you know that on some of the runs on the Darling they have bored to a depth of 700 feet? I have heard so.

Evaporation.

5101. Speaking of evaporation—do you think anything could be done to protect the water from the wind? Yes.

Floating stage.

5102. By growing water-lilies or weed? Yes, that could be done. My idea of protection is to have a floating stage or cover at the top of the tank. Of course that means expense where you have not timber close at hand. If I had plenty of timber I would have had covers to every tank; unfortunately we have only a limited supply; there is no pine within 30 miles of my place.

New Land Act.

5103. You think that under the new Land Act, giving security of tenure over a large portion of land will increase the amount of works carried on by the lessees? To a very large extent.

5104. Do the lessees employ any large amount of labour now? No; all work is at a stand-still.

5105. How do you raise the water into the tanks? By a M'Comas' pump.

Water-raising windmill.

5106. Would not a windmill answer the purpose? Not unless large overground supply tanks were constructed. The wind is very uncertain; thus it would be necessary to have at least three days' water supply on hand to feed the troughs, otherwise the stock must fare badly; in fact it would be madness to depend entirely on the wind as a motive power for pumping water.

Namoi and Barwon flood waters.

5107. Do you think that conserving a great body of water which passes down the Namoi and the Barwon in flood is only a matter of expenditure? I think it would be quite possible to do it if we had the money.

Tanks and vegetation.

5108. *Chairman.*] Do you find that in watering stock about the tanks the water produces vegetation in the vicinity of the tanks? I have never tried the experiment. The water in the tanks is of course pure water—it is rain water.

5109. In case of leakage from tanks does the vegetation spring rapidly? The tanks are beneath the surface; the treading of stock would prevent the growth of vegetation.

Silt tank.

5110. In constructing your tanks what provision do you make for silt that may be carried down by the supply course? I construct a silt tank to receive the water conveyed by drain from the rising ground.

Mr. F. Y. Wolseley. 16 May, 1885.

5111. In what way do you discharge the water into the tanks? By flume.
5112. Your tanks have been long enough in existence to determine the loss per year absolutely? I have one tank which was 18 feet; now it is only 2 feet deep.
5113. In what time is that? Five years.

Removing silt.

5114. Have you any ready means of removing silt from the tanks? No; it is my experience of removing silt that it is less expensive to construct a new tank. I have proved that in the last twelve months. I had an old tank cleared out, and it cost me more to clean it out than to make a new one.
5115. *Mr. M'Mordie.*] What means did you employ for cleaning out the old tank? Carts and shovels. I let the work by contract, and had to give the men 1s. 6d. per cubic yard; whereas I could get a new tank constructed at 1s. 2d. or 1s. 3d. per yard.
5116. Some system of taking silt from tanks quickly is a general want? It is a want which is very much felt.
5117. Has any system been suggested and carried out? I know of a system which is being carried out at the present time on the Haddon Rigs station.
5118. Could we get the result? I should think so if you communicated with Mr. Greaves, the manager of the station. I think the system adopted there is a very good one, but it requires alteration to make it perfect.

Cost of artificial feed.

5119. *Chairman.*] Can you think of any other information which would be of value to the Commission? With reference to the artificial feeding of stock, in the case of severe drought: supposing it were possible to irrigate the country and to procure artificial feed, I estimate that the cost of the feed for (say) 10,000 sheep, artificially fed for three months at a very low rate, would be £320 more than the actual value of the sheep.
5120. *Mr. M'Mordie.*] How do you arrive at the cost of the feed? I put it down at £4 a ton; I estimate that each sheep would eat 4 lb. weight of fodder daily—equal to 40,000 lbs., or about 18 tons, which, valued at £4 per ton, gives a sum of £72, the daily cost of feeding the 10,000 sheep.
5121. How many tons would you get off 1 acre of a good crop? I suppose something like 4 tons would be a good crop.
5122. And the cost of that would be £16? Yes; it cannot be produced in this district for less than £4 a ton. Bush hay costs £3 a ton.
5123. *Mr. Donkin.*] You think that, taking into consideration the labour of cultivating and cutting hay, it could not be produced here for less than £4 a ton? Yes; and you have to bear in mind that hay cannot be produced without irrigation.
5124. With plenty of water here, as well as on the Murray and Murrumbidgee, if the cultivation of hay had paid, would they not have tried it? They have tried it in some instances on the Murrumbidgee, but on a very limited scale, and only for the purpose of feeding a few stud sheep.
5125. *Chairman.*] What is the duration of the crop before it is reaped for hay? I have so very little knowledge of farming that I can scarcely say.
5126. If you could grow two crops of cereals per annum for hay, would that pay? If fodder could be delivered on the stations at 30s. per ton it might pay to artificially feed stock for four months. If stock were artificially fed beyond that period, I believe they would soon cost more than they were worth per head. In making this calculation, I have taken into consideration the labour necessary for feeding and tending the stock.

Irrigation.

5127. What could you afford to pay the Government for irrigating your land per acre, so as to produce a good crop? The question is so very wide that it would be almost impossible to answer it. It is impossible that they could irrigate the country to any great extent. They could not irrigate to such an extent as to produce a remunerative crop—that could be done only by a flood.
5128. *Mr. M'Mordie.*] But you go further, and say that it would not pay to provide the crops even if the water were provided for nothing? Yes.
5129. And people do so by pumping the water? I may qualify my answer by saying that if you could get the country thoroughly irrigated so as to grow lucerne the sheep would eat it; there would be no need to crop it, and then it would pay; but it would not pay to grow cereals.
5130. *Chairman.*] But taking lucerne for cutting, Mr. Wills-Allen gets 10 tons per acre per annum—would that pay? Under those circumstances I think it would; but I am taking it for granted that there is no expense for irrigation. Lucerne would pay if the water were provided for nothing.

Price of hay.

5131. *Mr. Donkin.*] Can farmers here get £4 per ton for all the hay they grow? Certainly. I do not know of any hay or chaff being bought in this district under £6. Of course it has been an extremely dry season, and there has been a great demand for fodder.
5132. But could not sheep do upon less than 4 lbs. of hay per day? Possibly they might; I do not think so. On the Murrumbidgee, where they fed stud sheep artificially, when the drought was over they found that the sheep had cost in their feed more than double their value; but they were of a special value to the owner, because he could not replace them.

Mr. Charles Norman called in and examined:—

Mr. C. Norman. 16 May, 1885.

5133. *Chairman.*] You are the proprietor of the *Walgett News*? Yes.
5134. Have you been long resident in this district? About five years.
5135. During the whole of that time you have been suffering from the drought? Yes.
5136. In this period have you had an opportunity of seeing the nature of the country over a large area? Yes.

Country.

5137. To what extent did your observations extend from Walgett? Up as far as Mogul and Narran.

Loss of stock.

5138. You know that there has been a great loss of stock in this district? Yes; I am a stock agent. I have sold large numbers of stock in this neighbourhood.
5139. Your business, then, would bring you into close relations with the stock-owners? Yes. I was connected with squatting in the Riverina for eight or nine years before I came here.
5140. In your movements here, then, your observations have been based on your former knowledge? Yes.
5141. To what extent has the loss of stock gone during the last five years? I could scarcely say; it is a very large quantity. I dare say, taking all the runs in this district into consideration, we have lost about 60 per cent.

5142.

Mr. C. Norman.

16 May, 1885.

5142. This loss arose in a great measure from the extremely dry weather? Yes, entirely from the severe drought.

5143. You think that no portion of the loss arose from over-stocking? In some cases possibly it did. I know many runs which were not over-stocked on which the loss has been very heavy. In the third year of the drought the land was absolutely denuded of vegetation. The country here cuts up more in a drought than in any part of Riverina that I have been in. Over-stocking.

5144. Is the present condition of the country better than it was at the time when that great loss took place? Yes, it is a great deal better now. Present condition.

5145. Do you think from its present condition that the squatters would feel justified in commencing to stock again to anything the same extent as before? I do not think so. The rainfall this year is not sufficient to warrant the squatters in stocking up. If there was the same rainfall next year, I do not think the squatters would stock their runs to anything like the extent at which they had them stocked in former years.

5146. Do you know the general system of water conservation throughout the large runs in this district? Yes; it is very simple. Water conservation.

5147. What is the most perfect of which you know? The only means adopted in this district consists of a system of tanks. Tanks.

5148. You heard the evidence as to tanks? Yes.

5149. Do you know of any system better than that which has been described? No.

5150. In your opinion, could it be improved upon so as to ensure a better and a more constant supply? I do not think so under ordinary circumstances. Of course if water could be brought into the tanks by any means from the rivers, or from wells, it would be a better means of keeping the tanks supplied. I know of several runs near Moree where the tanks are kept supplied by steam-pumping from the Gwydir. At Midkin several large tanks are kept supplied by pumping. Pumping at Midkin.

5151. At what distance from the river are those tanks? One is 8 miles from the river.

5152. How is the water conveyed from the pumping station to those tanks? It is pumped into a canal or drain; the water runs right into the tank.

5153. Has a level been ascertained by survey? I do not know what system is adopted. The water is obtained from the river, at a place called Muckabundi.

5154. From your own knowledge and from what you have heard, do you consider that a large proportion of stock is lost absolutely from the want of water? Not from the want of water alone, but from the want of water indirectly, because the want of water naturally causes a want of grass. I do not think that many stock lost in this district perished from the want of water, because most of the runs have frontages and can obtain water. Causes of loss of stock.

5155. I observe that the distance between the rivers is very great, and that the intermediate creeks are now completely dry: I should like to know how the stock without tanks can be maintained over this large district of the Jamison and Benarba? The whole of the stock between the Namoi and the Gwydir could be provided for by tanks and wells. At a point about 30 miles from here, just below Thalaba Creek, the river is stony. I think that if a dam were formed there the water would be sent up into the creek behind it. Thalaba Creek.

5156. What is the nature of the ground? I do not know, except that the river is stony.

5157. What is the nature of the country in the county of Finch to the north-west? The country is not I believe of very great value. Country.

5158. Are there no creeks in that large area? There is not a creek from Gundabloui to Walgett. Creeks.

5159. You know the county of Finch—is it closely settled? There is no settlement at all. Settlement on the river is impossible; the land is of such a porous nature that the smallest agricultural settler would starve. Settlement.

5160. Between the Barwon River and the Narran there is very little settlement for pastoral purposes at present? Very little.

5161. Could the land be improved by irrigation? Yes. Irrigation.

5162. And the nature of the country would permit of the upper waters of the Barwon being carried through it? I think it would.

5163. Considering that the question of water supply to station property is one of the largest expenses, if a constant supply could be laid on through this country, do you think that the squatters would pay a fair proportionate charge for the use of the water? I think that if a good system of land tenure were adopted—if they were certain to hold—they would undoubtedly do so. Water rate.

5164. Do you think that under these conditions they would have more expensive works for their own safety? Yes, under favourable conditions.

5165. In damming the water of the Barwon, to what extent would a moderate dam throw the water back? A dam raised near Walgett would throw the water back as far as Goagra. That is nearly 40 miles by water, but only 18 miles by road. Dam on Barwon.

5166. The dam would produce that result? I think a dam to the height of the river bank would do that. My reason for saying so is my observation of the river in flood-time.

5167. You know nothing of the levels? No.

5168. What is about the average width of that part of the river, and the depth from the top of the bank? I do not know. Width.

5169. Assuming the width to be 100 feet here, what would be the general averarge backwards? I think it is pretty nearly the same width.

5170. What is the depth? I suppose the depth is about 20 or 30 feet. The fall of the river is very small indeed midway between Walgett and Goagra. I have seen the water flowing up the creek towards Castlereagh. Depth. Fall.

5171. Does it return to the river at that point? It goes into a swamp near Castlereagh—Nagal Swamp. Nagal Swamp.

5172. Then it traverses a distance of about 20 miles? Yes; there has been no water in the swamp during the last three years.

5173. Having stored a large area of water in the vicinity of Walgett, in what way could it be made available for distribution except in the watercourse you have pointed out—would it command the country north and north-east of the Barwon? It would only command the country along the banks, unless canals were cut. Distribution.

Mr. C. Norman. 16 May, 1885.

5174. Are not the banks of the river higher than the country further back? I think the immediate banks are.

5175. In what proportion? I cannot say. From crossing the river often, my impression is that they are slightly higher.

5176. You do not know that by making a deep cut the water would flow to the level country behind? I do not.

Canals. 5177. Have you thought of any means by which if the river were dammed at this point the water could be used, except in the immediate vicinity of the river—do you not think it could be made a supply for the lower part of the Barwon towards the Darling? I have thought that canals might be constructed to water the country on each side in the counties of Denham and Finch.

Agriculture. 5178. Do you think that if we could establish a permanent water supply in the county of Finch, any portion of the water frontage could be used for agricultural purposes? Decidedly not.

5179. Why? I think I said before that the country on the river is of such a porous nature that even in the best of seasons it will not grow grass.

Soil. 5180. What is the nature of the soil? It is black soil. I have not enough knowledge of the soil to form an opinion as to why it does not grow grass. There is another place on the river Barwon, 8 miles

Dam. below Walgett, where a dam could be constructed.

5181. Would that be above Wansara ana-branch? It is above it.

5182. And you lose the opportunity of distributing when you get above it? Yes.

5183. Why could you not go lower down for your dam? At the point I have named it is rocky. I do not know that you will get a good site elsewhere in that quarter.

5184. If a dam were placed there, and if water were raised to the height of the present bank, could it be distributed? Only by canals; I think a dam there would throw back both rivers, together with the waters of the Pagan, the Thalaba, and the Pian.

Benefits. 5185. If we conserve water there by a well devised plan, would it be beneficial to the whole district? Yes, very largely.

Irrigation. 5186. *Mr. M'Mordie.*] Do you know of any irrigation carried on at Moree by means of pumping? I only know the pumping which I have mentioned before.

5187. But do they not grow crops by irrigation? No; as far as I know, the pumping is merely used for the filling of tanks.

Dam. 5188. You spoke of a site near Walgett as being suitable for a dam? Yes.

5189. What description of dam would you place there? It would have to be an overshot dam.

Mr. James Rowland Doyle called in and examined:—

Mr. J. R. Doyle. 16 May, 1885.

5190. *Chairman.*] You are Inspector of Stock in this district? Yes.

5191. How far does your district extend? To the Queensland border on the north; on the eastern side to Combogoland; on the western side to the Bogan; to the south-east as far as Goangra.

5192. You are acquainted with all the country in Benarba and a portion of Narran? Yes.

5193. How long have you been in the district? I came to Walgett in 1857.

5194. How long have you been in your present position? Nearly five years.

5195. Prior to taking this appointment how were you engaged? I was on the Ulumbi Station for many years.

Seasons. 5196. During all that time you have seen great changes of seasons—extreme droughts and moderately good seasons? Yes, but I have not kept an account of dates.

5197. The present drought is about the longest you have known? I think the drought in 1868–9 was

Stock. quite as severe, and told quite as heavily on the stock-owners in proportion to the number of stock they had; there was not the same number of stock in the district then as we have had since.

5198. At the time when you had really good seasons there were fewer stock? Much fewer; they were nearly all cattle stations then; now they are sheep stations.

5199. During the good seasons there was little to complain of as to grass and water? No, it is a splendid growing country when we get sufficient rain.

Sufficient rain. 5200. What do you consider sufficient rain? I have not kept a register; in a fair season we should have about 20 inches; we could not do very well with less.

Creeks. 5201. With 20 inches of rain would the creeks in the country between the Namoi and the Gwydir be well charged with water in the summer? We have no creeks extending any distance back.

5202. Do you know the present condition of the Pian Creek? It is very low, and has been for a very long time.

5203. Through how many properties do the Pagan, the Pian, and the Thalaba Creeks run? Between Wee Waa and Walgett, I fancy about ten.

5204. At the present time none of those lessees benefit by the watercourses? A heavy thunder-storm will furnish them with three months' supply in the best waterholes.

5205. The holes hold the water? For a considerable time.

Flood-waters. 5206. Do you think that the water, in times of freshes or floods, could not be conserved, or are there

Dam. soakages? An immense dam was swept away in 1864.

5207. How was it constructed? Entirely of earth.

5208. Was any provision made by means of a by-wash? It was too near the dam, and did not take sufficient sweep.

5209. Do you think a dam would stand if more suitably constructed? I do.

Series of dams. 5210. And would a series of dams in the Pian Creek be of service to the various runholders? Yes, they would give almost a constant supply.

Water conservation. 5211. I suppose you know that the runholders have gone to great expense in conserving water? Up to the last twelve months the system of tank construction had improved very much, but latterly work has been at a stand-still.

Insecurity of tenure. 5212. Do you know of any reason why the squatters should not extend that work so as to be perfectly safe under all conditions of drought? The reason assigned to me is the insecurity of their tenure. If they made large tanks a lot of selectors might come round them. One of the best runs here was ruined the

Capacity of tanks. other day by selection, after the holder had paid £80,000 for it. They have enlarged the carrying capacity of

of the tanks from 2,000 to 5,000 yards to 10,000, 12,000, and 15,000 yards; the small tanks were found to be dry when the lessee wanted water. I think that a tank of 10,000 yards capacity will stand longer with pumping than a tank of 20,000 yards capacity to which the sheep are allowed to go direct; they carry a lot of silt into it, and a lot of water out of it in their fleeces. In addition to saving silt from being carried into the tank, by means of a pump the last gallon of water could be utilized. Mr. J. R. Doyle. 16 May, 1885.

5213. Have you observed much well-sinking in the area of which you have spoken? A good deal, where there has been any prospect of getting fresh water; when fresh water was found in one place they have searched for it in other places in the vicinity. There is a vein of country running from Mooni down to the Narran Lake in which water has been found. Wells.

5214. Has it impressed you in any one instance as being more than ordinarily successful? There are two very good wells at Borora, near the Queensland border.

5215. On what run is that? The Gundabloui. On Gundabloui.

5216. What kind of well is it? Sand-drift, slabbed down about 6 feet square.

5217. What is the depth? I think not more than 30 feet; I know that they watered 1,300 head of cattle from it during a whole dry season. Depth.

5218. How is the water raised? Latterly by a horse and whim and self-acting buckets. Water-raising.

5219. Have you observed the result of the quick raising of the water? It lowers very rapidly, but rises again quickly. Supply.

5220. Do you know of any other people in this neighbourhood who could support that evidence? There is another well at Dungalear, between Narran and the Barwon, within a mile of the Borah Government tank. At Dungalear.

5221. What is the nature of that well? That is also a sandy soil.

5222. What is the water used for? There is a windmill, which supplies the garden, the house, and the the working horses. Windmill.

5223. Is the garden productive with that supply? As long as there is a full supply for it.

5224. You think that the country back from the Barwon, in the county of Finch, would be suitable for agriculture if it were irrigated? For pastoral purposes, it is some of the best land in this part of the country. Agriculture.

5225. Is it occupied? Yes, fully.

5226. Do you know of any wells on the banks of the Namoi? There is one at my own place, on the borders of the township, and there are several in the town. There is one at the brewery. Wells.

5227. Do you think that water is obtained by soakage from the river? I am hardly inclined to think that.

5228. Is the well at the brewery well supplied with water? Yes. My own is the same. It is much harder than river water.

5229. What is the depth of the well at the brewery? About the same as my own—about 42 feet. Depth.

5230. What depth of water does it give you? Sometimes we have 5 or 6 feet of water. I think my own has silted up of late years. I have known it to have 7 or 8 feet of water. The flood rose on one occasion over the surface, and we thought we should have to bale it out, but it lowered very rapidly to its own level, so that the ground at the bottom must be very porous.

5231. What is the size of your well? It is a circular well, about 4 feet in diameter. Size.

5232. Have you never applied a heavy test so as to see how much water you could draw without exhausting it? I have not. Supply.

5233. What do they draw in the brewery? I do not know, but I know it is a heavy supply.

5234. And the well never runs dry? No; the river is close to the brewery, and although the river might at any time be dry there would be water in the well.

5235. You think there is an underground current near the river? I do; I know a man who sank a well through a stiff pipe-clay in the centre of the bed. He sank the well 8 feet deep only, and the water then came in. He had 7 feet of water next morning, which he continued to use for months. That was at the worst time of the present drought. Underground current.

5236. Do you know of any other places where the bed of the river has been tapped for water? I have known of other places where they went 20 feet deep in the river bed and did not succeed in getting water. That was higher up the river. Wells in river bed.

5237. Are there any known indications in the sinking of wells with a view to avoid salt water? Only in the vein of country to which I have previously referred.

5238. What are the indications? A peculiar kind of timber. Indication of water.

5239. What timber do you find generally over suspected basins of salt water? I do not know of any difference in the timber on the surface. You may get salt water in one place, and within a few yards you may get fresh at the same depth. Timber.

5240. What timber is an indication? The foliage is generally greener and fresher where you find a fresh-water well.

5241. Have you observed the strata in those wells? Those I have spoken of are in sandy soil. Strata.

5242. Have they been carried to the full depth? Not always.

5243. What was the change as you approached the water? It is pipe-clay, and then there is less drift. The water comes in so fast that unless you close the box you cannot get down to the depth you intend. I think you would get a better supply if you went right through the drift, but you would require engineering skill to enable you to do so. I believe that all these wells are soakage wells. One of the best of this kind of wells is on Mr. T. K. Scott's run at Gingi. About twenty years ago I was camped where that well is now, and a very heavy thunder-storm occurred, the rain lasting about an hour and a half, and leaving a sheet of water at the spot where the well now is. Any one would have supposed that the water would have lasted six weeks at least, but in the morning at sunrise there was not a drop of it visible. Soakage.

5244. Taking this large area, in which district is there a constant supply? I do not know of any that you can depend on. Even the Gingi well, which is the best in the neighbourhood, would not stand a very heavy tax. If it were called upon to water 10,000 sheep I do not think it would stand the strain.

5245. Do you know of any large depression in the course of any of the dry creeks which by treatment might be made large water reserves? I think the Narran Lake is worthy of some study in that respect. The Narran in good seasons has been known to run for nearly twelve months. During those twelve months there were three or four floods in the river, carrying down an immense body of water, all of which went into Depressions. Narran Lake.

Mr. J. R. Doyle. 16 May, 1885.

into the lake and never left it—it did not discharge into the Barwon. There are large inlets from the lake running back for miles. These are surrounded on two or three sides by ridges which would be well adapted for throwing the water into the lake.

5246. Do you propose that the lake should be made a large reservoir? The proprietor of the adjoining station recently sank two wells. The soil consists of black coarse sand. You would not have looked for water in it, but an excellent supply was obtained. This was in one of the spurs of the watershed leading to the lake. The water was found in rock. There appears to be a rocky bottom to the lake. Mr. Mein is the lessee of the surrounding country.

Underground outlet.

5247. You do not know whether there are any outlets from that lake running towards Brewarrina south-westerly? I do not know, but I fancy there must be an underground current from it. The lake is so situated that it might drain to the south-west.

5248. *Mr. Donkin.*] Is there any water now in Narran Lake? Not in the main lake; there is a succession of lakes which fill one after another.

5249. Is there any depth? I never went into it.

Evaporation.

5250. It soon evaporates in dry seasons? The evaporation must be great, or there must be a great undercurrent.

5251. If the water were intercepted at any point, could it be conveyed to other parts of the country? In some instances you are surrounded by dry land.

Mr. Vincent Durand called in and examined:—

Mr. V. Durand. 16 May, 1885.

5252. *Chairman.*] What is your occupation? I am a gardener.

5253. Where is your land? Two miles up the river, on the Barwon.

5254. How long have you been resident here? Eight years.

5255. During that time you have been farming and gardening? Yes.

Farm.

5256. What is the size of your farm? 40 acres.

5257. Do you make a living on that farm? Yes.

5258. In what way do you use this 40 acres? I grow fruit and vegetables, and hay when there is a good season.

5259. Did you select the site on account of the quality of the soil? I thought it was best for gardening. I do not think the part I hold is much better than the surrounding country, but it is high land and out of reach of flood-waters.

Irrigation.

5260. Do you water your garden? Yes, by wells; last year the wells were not sufficient.

Wells.

5261. Is that river water? No, I do not think so, because when the river is in flood the level of the water in the well is not altered.

5262. What are you doing now for water? I get it from the river, raising it by pumps.

Pumps.

5263. What kind of pumps? One is 1½ inch, and the other is 2 inches.

5264. Have your any reservoir? No, I only raise the water on to the ground.

5265. Have you ascertained what you raise daily? No, I have not.

5266. How long do you pump? Sometimes all day. We generally begin early in a morning and cease at 12 o'clock. We then begin again at 5 and continue until dark.

Cultivation

5267. How many acres have you under cultivation? 10 acres of fruit and vegetables.

Produce.

5268. From these 10 acres you can produce enough fruit and vegetables to provide an income for yourself and family? We are now only four in number, but for the first five years eight of us used to live on the farm.

5269. This number of persons was maintained on the produce of the ground? Yes.

5270. Could you have done that if you had had only the ordinary rains? No.

5271. How many acres would it have taken with the ordinary climate? It would be impossible to say.

Effects of irrigation.

5272. Some years you might raise a crop, but that would go a very short way towards maintaining your family? You can do nothing without irrigation, but with irrigation you can grow anything.

5273. You think the soil on the banks of the river is suited to agriculture if it is watered? I do.

Water rate.

5274. If you had a farm of 500 acres, what would you be prepared to pay for a water supply for irrigation? £1 an acre.

Pagan Creek.

5275. You know the Pagan Creek? Yes.

5276. Is there a large basin there? Yes, it is very large.

5277. How far back from the Barwon River? About a mile and a half, where it commences, but it extends very far.

5278. If the water were prevented from flowing into the Barwon, it would be a big waterhole? It would.

Mr. Charles Neam Vaughan called in and examined:—

Mr. C. N. Vaughan. 16 May, 1885.

5279. *Chairman.*] You are a general merchant, and resident in Walgett? Yes.

5280. How long have you resided here? About seven years.

5281. Prior to the settling of the town of Walgett you were connected with the navigation of the river? Yes, I have been seventeen years on the Darling.

Creeks.

5282. In your experience during the time that the Darling was navigable, you have had opportunities of observing the state of the creeks discharging from that river? Yes.

5283. What was the length of your experience in navigating the navigable portions of the Darling and Barwon? It has extended over the last seventeen years.

Navigation.

5284. Can you give the latest date when you were able to navigate these rivers as far as Walgett? In 1877 I had two vessels specially constructed for the navigation of the river between Brewarrina and Walgett, intending them to trade between the two places. At that time I had interests in four places; Wilcannia, Bourke, Brewarrina, and Walgett, and I thought to run the trade at this end by means of these two vessels. In November, 1878, the flood-waters came down sufficiently to enable us to carry out this object. We brought the vessels to Brewarrina as far as the township to the point of Pitt-street. The river was again in flood in April, 1879, and again in August and September of the same year. At that time it was unusually high here; I should imagine that the depth of the water would be, as near as I can say,

Floods.

Mr. C. N. Vaughan. 16 May, 1885.

say, 40 feet above the present summer level; I know by observations at various depths, having had occasion to mark them by cutting the limbs of trees to let the steamers get through. In September of the year I have named I penetrated the Barwon as far as Collarindabri with the steamer "Brewarrina;" in that journey I traversed 150 miles of water.

5285. What was the draught of the steamer? I think that she was running with a draught of 4 ft. 6 in., but she was built to run with a draught of 30 in.

5286. Your load line was 4 ft. 6 in.? Yes.

Speed.

5287. In calculating your chances of making a trip on a winding river like this, how long would you calculate that the journey would occupy from Walgett, against a fresh for a distance of 150 miles? The greatest average speed would be about 4 miles an hour, unless you had exceptionally strong engines.

5288. In venturing so far up the river, would you calculate how long the flood-levels would stand at sufficient height to give you a draught of water? Yes.

Duration of flood.

5289. How long did the river remain in flood? For several months at that time, but I cannot give you the exact date. Several events impress the fact upon my memory very clearly: it was about the first or second time of the holding of Quarter Sessions here, and the Judge, the Crown Prosecutor, the present Speaker of the Assembly, and one or two other barristers were here. I was summoned as a juror, but His Honor allowed me to go with my vessels, so that I might return to take the party on to Brewarrina and Bourke, there being no other means of transit.

5290. During the sitting of the Court you had time to go up the river and back? On the conclusion of my trip up the river, I went up the Pagan as far as Eury Eury and brought down a clip of wool. At that time I had a telegraphic communication from Gundawindi as to the state of the river, and upon that we based our calculations as to how long the flood would last in the Barwon.

5291. What is the distance from the entrance of the Pagan Creek to the Eury Eury station? About 12 miles.

Pagan Creek. Thalaba Creek.

5292. As a matter of fact, does not Pagan Creek widen out into a large basin at that point in its course? I could not say. I also entered Thalaba Creek, at the Brothers Station.

5293. Is the creek deep there? I think that it would be a deep channel there.

Dams.

5294. Do you think that it would be possible to deal with that outlet by damming it? Yes, it would hold the water back for miles.

5295. How far? I do not know much about Thalaba Creek, but I know that it is flat country for many miles.

Sectional area.

5296. Has the creek a large sectional area? At that time it was as wide as the Barwon.

5297. If the water were impounded in it, would there be a very large quantity? Yes.

Eury Eury.

5298. What are the features at the Eury Eury Station? There is a very large reach of water.

5299. Do you know Pian Creek? No; I have travelled on it, but it has always been in a dry state.

5300. Do you think that water might be intercepted at different points on that creek, so as to make permanent water? Yes.

5301. It is about 110 miles long? I am not sure; I suppose that would be something like the distance.

5302. You do not know the outlet to Pian Creek on the Namoi? No.

5303. Were you towing a barge on the river? No.

Dimensions of steamer.

5304. What was the length and beam of your steamer? She was side-paddled; I cannot say the length, but I think about 60 ft.; she was about 8 h.p., and would go from 3 to 4 miles an hour against a current.

5305. What could she do in still water? From 8 to 10 miles.

Current.

5306. What do you estimate was the rate of the current against you? About 3 miles; it varies at different points of the river; the banks are very low-lying, and the water sweeps across the flat country.

Width.

5307. Suppose the river were to fall low, just leaving enough navigable water, would there be enough room for the steamer to clear it with her paddle-boxes? Yes.

Inlets.

5308. Between Bourke and the highest point at which you have been on the river have you noticed whether there were large inlets at flood-times? On this side of the river between here and Bourke there are two or three; there is Maara Creek and the Macquarie Marshes and Bogan River.

Full of creeks.

5309. Do you know the Macquarie? I do not know much about it. I may mention that all the creeks between Brewarrina and Walgett fall in the same ratio as the river when the flood-water subsides, and gradually become empty.

Current.

5310. Did you find that there was a stronger current when you were approaching Bourke than after you had left it coming up this way? I did not make any observations.

Sections.

5311. Is there any difference in the appearance of the river in regard to sections, as compared with any portion above Walgett? It may be a little wider, but the difference is very slight.

Waste of water.

5312. Did it lead you to suppose that there was any waste water in the swamps, or by soakage? I have not thought of it; the current appeared about the same in any portion of the river except at the sharp bends.

5313. Do not the people who navigate the river think that a great deal of the flood-waters must be absorbed before they reach the lower rivers? Yes; there are exceptions in which the water remains for a time.

Dam at Collarindabri.

5314. Suppose we were to dam the river at Collarindabri, where I understand there is a rocky ford, the water I suppose would be discharged over the county Finch towards the Big Warnambool and the Narran swamp? Yes; from a point near Terribie on the Barwon, on the Dungalear side. There is a creek supplied by the flood-waters of the river; that is discharged through the county Finch to a point near the Big Warnambool; the course of the creek is more than 10 miles distant from the Barwon. There is another creek which runs from the Mooni from above Gundabloui, and thence in a south-west direction towards the Big Warnambool; that creek I believe has not run since 1879. At a point about 6 or 8 miles below Walgett there is a rocky bed where a dam would back the water up as far as Goongra. When the Barwon is in flood and the Namoi at ordinary summer-level the flood back-waters extend back into the Namoi for a distance of several miles.

Development of the town.

5315. *Mr. M'Mordie.*] During your seven years' residence here has the township grown much in size? Considerably; it was growing very rapidly indeed until the present drought, which has checked its progress.

5316. It has been getting smaller? No, but it has been quite at a standstill of late; we only need a return of good seasons to ensure its continued progress.

Population.

5317. Has it as large a population now as it had twelve months ago? No, because families depending on local labour have had to seek employment elsewhere, on account of the drought.

Mr. C. N. Vaughan. 16 May, 1885.

5318. *Mr. Donkin.*] You know the river from Walgett to Brewarrina? Yes.
5319. What would be the difference in distance between a straight line and the bends of the river? I think that it would more than double its distance by the river.
5320. *Chairman.*] Do you know the difference between the level of Walgett and that of Bourke? No. Judging from my experience, I do not think that there would be much inducement to warrant any expenditure to provide means of navigation between those two points. If a railway line were constructed from Narrabri we should have all the accommodation which would be required.

Navigation and railway.

5321. Is it more important to keep the navigation open than to supply this thirsty country with water? To provide for navigation would involve far greater expenditure than would be necessary for the conservation of water.
5322. Which work would benefit the greater number? Many more would be benefited by the distribution of the water over the surface of the soil.
5323. You have seen the results of irrigation of small patches of soil on the banks of the river? Yes.

Irrigation and produce.

5324. You know that with cultivation and irrigation the soil will grow fruit and vegetables? Yes; the soil is capable of producing almost anything, so long as it has the necessary water. I produce a quince grown on the banks of the Namoi.
5325. Did you get that growth without the assistance of irrigation? No.
5326. But with irrigation the cultivation of fruit and vegetables might be carried on to an unlimited extent? Yes.

Mr. Walter Jones Pearson called in and examined:—

Mr. W. J. Pearson. 16 May, 1885.

5327. *Chairman.*] You are a resident of this district? Yes.
5328. You have been a resident here since 1879? Yes; I have been managing Ulumbi Station.
5329. Have you been managing it all the time? Yes.
5330. Where is it situated? It adjoins the town of Walgett; it is on the west side of the Namoi, near the junction of the Barwon.

Ulumbi Station.

5331. You have seen the worst of these dry seasons? Yes. I came when the 1878 drought broke up.

Area.

5332. What is the extent of your station? 36,000 acres. It was originally 46,000 acres.

Stock.

5333. What stock does it carry? About 8,000 sheep and 800 cattle.*

Losses.

5334. Without considering the increase, do you find that after all these dry seasons you have the same number of sheep? No. We have had losses through the drought, but it does not account for the stock going away, because we have removed a certain number.
5335. What did you lose by the bad seasons? About 5,000 sheep. We should have lost more if we had not removed them.
5336. At the time of their removal you had no feed on the station? Nothing.
5337. In what way do you account for it? Want of rain.
5338. Could you have held on if you had had a good supply of water on the surface? Yes.

Tanks.

5339. Do you depend on the Namoi for the watering of stock? My main watering places are tanks, but if the tanks gave out I should be forced to the Namoi.

Watting of stock.

5340. Why do you not prefer the Namoi? It is too far for the stock to go for water if water can be obtained in the back country.
5341. If your flocks were on the river bank you would water them there? Certainly.
5342. In the present state of the river could you water them there? I have not been unable to water them there since 1879; the waterholes never go dry—they have never been so low but the sheep could be watered at them.

Soil.

5343. What is the nature of the soil at those waterholes? Sometimes sandy, and sometimes black soil.

Tanks.

5344. You never had occasion to search for water in the river for the watering of sheep? No.
5345. How many tanks have you on the back run? Seven.

Capacity.

5346. Are they all of the same capacity? No; they vary from 2,000 to 5,000 yards.
5347. Which size do you consider the more economical? I prefer the 5,000 yards tanks. I think you get a greater depth, and they are quite sufficient for the number of sheep I had in the paddocks.

Form.

5348. What is the form of construction you like best? I would prefer a tank with a side batter 1 to 1, if the ground is firm, coupled with fencing in to keep the stock from it, pumping the water up for their use.
5349. Is there not great danger in high winds of the water eroding the banks and of their falling in? I have never found it so.

Spoil.

5350. How do you dispose of the earth which you take out of the tank? It is put about a chain away, or if it can be used for the conservation of water it is put round the banks. If you allow sheep to go to the waterhole it is better to take away the earth.

Evaporation.

5351. Have you made any observations as to evaporation? I cannot say that I have. The lower the tank gets down, the less the evaporation. I had a tank which, after a short interval, sank 1 foot in the absence of stock.
5352. Before watering the stock, do you gauge the level of your tank? No; in a small tank we know when we are going to find the bottom.

Silt.

5353. What provision do you make to prevent silt from going into the tank? We have catch tanks.
5354. Do you find that they prevent the silt from entering the main tanks? They get all the silt out of the drains, but not the silt that the sheep tread in off the batters.
5355. Have you found since you have been on the station that you have lost a tank by silting? No. One tank is silted three feet in eight years.
5356. What means do you adopt for cleaning the silt out of a tank? I have never yet had occasion to clean silt out of a tank. Having regard to the expense of the present mode of cleaning tanks I would rather abandon the tank. If it were a very large tank it might pay to clean it out.

Pian Creek.

5357. Do you know of any large holes in the Pian Creek that might be used for storage of water? No; I know that it lies in holes, but I have not noticed any of the places you indicate.
5358. Is it an impermeable bed? The creek retains the water in the holes for a certain time, but they eventually go dry.

5359.

---

* Note (*on revision*):—This was in 1879; since then there have been more, up to 20,000 sheep, and as low as nil in 1884.—W. J. P.

5359. Suppose the water could be replenished, could we keep constant water throughout the creek? I think so. Mr. W. J. Pearson.

5360. To how many runs would it be serviceable? I do not know. It would be very useful near the outlet on the stock route. I may say that I have a small dam on the Namoi, but it is only an earthen dam. 16 May, 1885.

5361. How did you stop the flow of water when the dam was being laid in? I put a log on the bottom, and put in the earthwork before the water rose over the log. Dam.

5362. What was the flow in the river at the time you made the dam? I cannot say.

5363. What was the height of the log? About a foot. The river filled up 3 feet 6 inches to 4 feet behind the dam in a week. Height.

5364. What length was the dam? About 75 feet. It was made in a narrow place where there are two channels, one lower than the other. Length.

5365. How was it that the water did not rise more than 3 feet 6 inches? There was no water at the back, and the river stopped flowing. In case the water should rise to the crest of the dam, we provided an outlet in the second channel.

5366. Has the dam stood? No, it washed away, but it answered as a temporary dam. The water went back 2 miles to 2½ miles. The water remained six weeks, but diminished considerably by soakage and consumption by sheep; then the dam was washed away.

TUESDAY, 19 *MAY*, 1885.

At Brewarrina.

Present:—

MR. DONKIN, J.P., | MR. FRANKLIN, C.E.,
MR. M'MORDIE, M.I.C.E.

F. A. FRANKLIN, ESQ., C.E., IN THE CHAIR.

Mr. John Henderson called in and examined:—

5367. *Chairman.*] You are a resident of the district? I reside at Quantambone. Mr. J. Henderson.

5368. You have been a long time resident here? Four years.

5369. During that time you have suffered from extremely dry weather? Yes, during the last two and a half years. 19 May, 1885.

5370. You do not know the state of the weather as compared with former years? I have a record of the rainfall on an adjoining station. The record has been kept from 1872. The fall for 1883 and 1884 was smaller by 3 inches than the fall in any season since 1872. Rainfall.

5371. During the four years you have been in the district, have you observed a large loss of stock? Yes; it is variously estimated at from 20 to 30 per cent; in some instances considerably more. Loss of stock.

5372. By what was that loss occasioned? By want of both grass and water on many runs. Causes.

5373. A greater abundance of water would not have kept the stock alive without feed? No; unless with scrub, which we have not got on the north side of the Darling. I know of an instance in which stock were kept alive for twelve months by watering-tanks and by the felling of scrub; they had no grass, but they managed to keep their stock alive.

5374. Is your run on a river-frontage? Yes, on the frontage of the Barwon.

5375. Your station is very favourably situated with regard to water? Yes.

5376. The Barwon has been generally running during the past four years? Yes; very feebly sometimes, but always running. The Barwon

5377. Do you know whether any attempt has been made to keep the water back by means of dams? Not that I am aware of. Dams.

5378. I see that your run is watered on the western and north-western sides by the Culgoa? Yes. The Culgoa.

5379. Have you made any endeavour to keep the water back on the northern side of your run? On the Culgoa we, with our neighbours, have two overshot dams. Overshot dams.

5380. What is the result of these dams? One of them has been a thorough success; that is the one nearest the Barwon.

5381. How far is that from the junction with the Barwon? It must be about 25 miles.

5382. What is the nature of the dam thrown across there? It is constructed of timber, and the front slope is formed of earth against a puddled wall, as follows:—A centre row of piles 9 inches in diameter at right angles with the axis of the stream, 6 feet apart. The centres are capped with sawn timber 6 inches by 8 inches, secured by bolts through the head of every pile. They are 9 feet in the ground. These are supported by ties and struts up and down stream, fitted to dwarf piles sunk 5 feet in the bed of the river. On the up-stream side there is a puddled wall to the depth of the central pile 3 feet in width by the length of the dam. The filling in on the up-stream side is of ordinary earthwork, to the pitch of about 3 to 1. There is an apron extending 20 feet by the width of the river, consisting of weatherboards attached to a frame supported by dwarf piles 5 feet apart, and 5 feet centres. The crest of the dam is 8 feet 6 inches above the bed of the river. Construction of dams.

5383. Do you find that dam effective? Quite successful. There was a little scour about 50 yards below it, caused, I think, by a tree in the bed of the stream. Scour.

5384. There is no scour at the foot of the apron? No.

5385. Did you find it necessary to take the apron up the sides of the bank? Half-way up. It is carried across the flat bed of the creek and up the slopes to a corresponding height with the dam. Apron.

5386. Did you find any tendency in the banks to give way at the flanks of the dam? No.

5387. Did you extend the dam into the banks for any distance? Yes, for nearly 30 yards. We had a small dwarf wall of about 3 feet under the ground and above the banks on the flat ground. It is a wing, and it is constructed to prevent the water from flanking the dam. Dam in banks

5388. You have never observed the velocity of the water in flood-time? No. Velocity.

5389. Can you give us an idea? It is a sluggish current—it is slower than the Barwon. If the Barwon is very low and the Culgoa is flooded it is faster. It gets away very rapidly.

Mr. J. Henderson. 19 May, 1885.

5390. What would be the height of the average banks of the river above the crest of your dam? About 12 feet or 20 feet from the bed of the river.

5391. How far does the dam throw the still water back in the river? About 10 miles.

5392. That practically gives you 10 miles of permanent water frontage? Yes.

Use of water. 5393. And how do you avail yourself of the water you impound? I merely use it for the supply of stock—I do not raise it for irrigation purposes. I know of one case on the Birie where it could be done without raising it all. There is a channel where the water has run down on two or three occasions; there is an earthen dam there.

Levels of country. 5394. Suppose you carried a line of levels from the dam on the Culgoa, what would be the nature of the country? You would find it higher than the banks of the creek.

Dams. 5395. Do you know whether they are adopting the same principle above you on the Culgoa? Yes; I do not know whether the dams are actually erected, but contracts are let for the erection of two dams.

5396. You do not object to their placing extra dams up there? Not to overshot dams.

Current. 5397. How long would it take you to fill your dam with the ordinary current of the stream? I have known it to run over three hours after the current reached it—that is, when quite empty.

5398. I suppose there is generally a current running? For months at a time there is none at all.

5399. You fill the dam with an ordinary fresh, and get permanent water? Yes.

Waterholes. 5400. What would be the consequence if you were to leave the river entirely without obstruction? There would be several waterholes. They would last about three or four months; they could not be considered permanent.

Width. 5401. What would you consider the average width of the water surface with a wedge of 8 feet 6 inches deep? About 50 feet.

Cost of dam. 5402. What would be the cost of erecting such a dam? About £600.

5403. Do you think that the price could be reduced by adopting another system of construction? Yes; and the dam I am speaking of cost us more than usual, because it was constructed at a time of drought, when carriage was high.

Apron. 5404. I suppose the apron might be made of material other than planking? I should prefer to have it of stone.

5405. And if it were not available, would not corrugated iron do? Yes.

Slope. 5406. Would it not also do to hold back the slope of the earth? I would prefer planking. If the piles were put closer together it might do, but the pressure of the water might break the joints. I have used galvanized iron in another instance near Wilcannia. It was one-eighth of an inch thick; it answered in that case.

Other dam. 5407. Have you made any other dam on this river? At a distance of 10 miles above the dam I have been describing there is another; it is at the junction of the Culgoa and the Birie.

Result. 5408. Was it a success? It has failed on two occasions through the water passing under the planking. The piles did not reach to the bottom of the drift; the consequence was that when there was pressure above ground the stream passed right through underneath.

5409. Did it attain any height before the pressure affected the foundations? It had no great height; perhaps there were about 6 feet of water. I think we have removed this difficulty by deepening the planking and piles, carrying them 6 feet lower down to a firm bed; they now go 15 feet down.

5410. Did you sink puddled trenches 15 feet? Yes.

5411. How did you dispose of the water? There was a little soakage to contend with, but there was not more water than could be baled out.

Nature of beds. Drift. 5412. Do you consider that the beds of these rivers in the black-soil country are impermeable? Yes, excepting places where there is a large deposit of sand. The Culgoa has a great deal of drift, but we have not found it to be any drawback.

Silt. 5413. Did you find a large deposit of silt at the dam after a fresh? There has been no perceptible deposit.

5414. In your opinion, a dam similar in construction would be available for most of the rivers and creeks in this flat country? Yes.

5415. How long has the dam been up? Eighteen months, and it has been fully charged twice.

5416. How long is it since you had it charged the last time? Just two months ago the flood was at its height. At the present time the dam is perfectly full, and there is a very slight stream going over it.

Billabongs. 5417. Are there any billabongs on the Birie of any capacity for storing purposes? None that I know of; I have heard of some higher up.

5418. Do you know of any on the Culgoa? They have some on Milroy just above us.

5419. Are they utilized for the storage of water? Yes.

Dams. 5420. They are dammed at the mouth? Near the centre or lower end, I believe.

5421. And the water is stored at times of fresh or flood? Yes.

5422. You do not know how the dams are constructed? They are earthen dams. There are no sluices; they are made so high that the water never passes behind them.

Flood waters. 5423. Suppose there were only a partial flood which did not mount to the crest of the dam, the supply would not be replenished? No; the flood-water enters from above.

Under-sluice supply. 5424. Then no provision is made to ensure an under-sluice supply? No, but I think it would be an advantage to have such a provision.

5425. Do you know if the attempt has ever been made? No, I do not. I only know of one sluice, and that is near Wilcannia.

Storage. Soakage. 5426. Do you think that if, in this flat country, large quantities of water were stored on the banks of the rivers it could be utilized in time of drought, and could be sent into the river again? The storage would have to be very large, because the soakage is so great. Of course it would be beneficial to the lower parts of the river.

Waterholes. 5427. Is it not the case that in extreme droughts the waterholes in the lower parts of the Darling become stagnant for want of a current? They become very brackish.

Brackishness. 5428. Would a fresh supply reduce that brackishness? Yes, the water would be kept sweet.

Tanks. 5429. Have you any surface tanks on your run? Yes, a good many.

Excavation. 5430. How are they constructed? By excavation. The country is so flat that we cannot utilize the earth. As a rule we generally put it round the excavation in the form of an embankment, but it is of very little use to us.

Mr. J. Henderson.

19 May, 1885.

5431. What do you consider the most suitable size of tank for a run? A square tank with slopes about 3 to 1 on each side, unless the water is to be pumped out.

5432. Of what depth? About 14 or 15 feet, giving about 10,000 yards.

5433. Does that give a permanent supply? For a moderate quantity of stock; it will water about 5,000 sheep and be permanent for them.

Stock watering.

5434. When you do not water from the tanks, what provision do you make for the stock? It is pumped out as a rule, but I have not here done so, only in another part of the Colony; we pumped it into a receiving tank, and from there we let it fall into the troughs by means of valves.

Pump.

5435. What pump do you use? The M'Comas' pump.

Evaporation.

5436. Does evaporation at certain times take place more rapidly than at others? A great deal more rapidly at times. High winds are worse than extreme heat.

5437. How does the wind act on the water? The heat and wind combined seem to lick it up; the wind does not wash it up the embankments.

Spoil banks.

5438. Then when you lift the water would it not be an advantage to keep the spoil banks as high as possible? Yes, undoubtedly.

Area of run.

5439. What is the extent of your run? About 400,000 acres.

5440. Do you keep sheep or cattle? Sheep.

Number of tanks.

5441. With two natural water frontages, how many tanks have you made? We have twenty-six large tanks.

Capacity.

5442. Of a capacity of how much on the average? About 6,000 yards.

5443. Is that necessary in addition to the river supply? Yes; and we feel the necessity for making a few more.

5444. The Culgoa, the Birie, and the Bokhara, all discharge towards the Barwon? Yes.

The Birie.

5445. And do they discharge in the same ratio—are their slopes equal? The Birie has the least channel of the three, and discharges more quickly; the Culgoa runs next, and the Bokhara runs last.

The Bokhara.

5446. So that a very large tract of country might with a low flood be deprived of water from the Bokhara? Yes. There was an instance of that this summer. The Birie waters ran for four months continuously before the Bokhara ran through.

Regulation works.

5447. Do you think it would be an advantage to regulate the waters down the Birie so as to give you an equal discharge in the two? Yes.

5448. And you think that is a matter worthy of investigation? I do.

The Culgoa.

5449. How far from the junction of the Birie and Bokhara do both these rivers junction with the Culgoa? I am not certain about the distance—I think it is about 30 miles; the Culgoa is evidently the main stream.

Regulation works.

5450. If we could bring the currents to about equal force and discharge we could perform the same operations as to damming, both in the Bokhara and the Birie? Yes. The Bokhara has a great many dams in it already, enough to guarantee a permanency of water if the floods were equalized at the junction.

5451. All the work in these rivers has been done by private enterprise so far? Yes.

Private enterprise.

5452. Do you recommend the continuation of private enterprise in this work? Yes, in the way of overshot dams. The residents on the Bokhara are prepared to go to the expense of erecting a small overshot dam on the Birie to equalize the waters.

Creeks between Narran and Bokhara.

5453. Supposing that you equalized the waters, would it be possible to drain a portion of the water to run down between the Narran to the Bokhara? There are a few creeks which intercept the two rivers, running from one to the other, that is which run to the Narran and the Bokhara. I know of no creeks running parallel to either river.

Narran Lake.

5454. Would it be any advantage if the waters were prevented from running into the Narran Lake, and were conveyed parallel to the Bokhara down into the Narran country, so as to avoid the loss in the lake itself? Yes, it would water more country.

5455. Do you know of any dry creeks there? I know of some which discharge after the lake is filled.

Diversion.

5456. Would it be possible to convey the water from the Narran on higher ground above the lake, and connect with the creeks at the lower parts of the lakes, so as to get the water into the impermeable country? Yes; by connecting the present channels by cuttings, and making cuttings from the lower end of the lake in a south-westerly direction to the Barwon, would water more country than any other means I know of.

Creeks.

5457. You know of creeks running in that direction? Yes, the water has actually run there.

5458. What would be the distance to get the water from the lake into the lower channel? 20 miles.

Supply.

5459. Is there a large supply of water from the source of the Narran into the lake? Yes, at times.

Channels.

5460. No one channel that you are aware of would convey the water in the direction you indicate? No; I think that the channel might be made at about the level of the lowest part of the lake into the Barwon.

Creek from Narran towards Bokhara.

5461. What extent of country would such a work benefit? About 10 miles on each side of the cutting. I do not know that the channel ought to be put at the lowest part of the lake. From the top end the natural fall of the country is towards the bend of the Bokhara, a distance of 20 miles. A creek already exists in that direction. It would require deepening if the water were made to run often; it has been known to run, I think, only on two occasions. It would of course have to be dealt with at its junction with the lake. There is another tributary running due south from the Narran Lake to the Barwon; it discharges near the Booroona Station.

Wells.

5462. Have you done anything in the direction of well-sinking? I have no wells; we have never got through the salt-water; we depend upon the surface water. One of our neighbours has had a bore at work for ten months, and has not yet succeeded in getting fresh water; that is on Milroy. In most of the sinkings water has been found at about 40 feet from the surface.

Depth.

Surface water.

5463. Then you think that the attention of the Commission should be devoted to the storage of surface water between here and Walgett? Yes, between these points and Bourke.

5464. You never kept any register of the discharge of these three rivers? No.

Equalizing of Birie flood-waters.

5465. Have you any general information which you think would be of service to the Commission? I may say that some of the settlers on the Birie think that the equalizing of the flood-waters may injure them. I think that the persons who would suffer most would be those at the lower end of the Birie, Armstrong & Co.; and ourselves, and we are in favour of the thing being done. We are also interested in the Bokhara. All the Birie residents get their supply before we get it. I think the flood-water is ample for both. I think the

Mr. J. Henderson. 19 May, 1885.

the Bokhara people would modify their petition if the Birie people would agree to let the proposed overshot dam be a foot lower than the bar on the Bokhara.

5466. *Mr. Donkin.*] You mentioned the loss of stock? Yes; it has been about 30 per cent.

5467. Is that the general loss? I think, taking it all round, that would be about it.

Loss of stock. 5468. At Walgett we were told that the loss had been 60 per cent.? It would not average that here.

5469. Did you lose any stock through want of water? Yes, I did. We had some country that was unavailable through want of water, although we were usually well supplied with water on the frontages. When things became extreme with us we let the stock go back into that country. They had to go 15 miles back from the water to these paddocks.

5470. You use M'Comas's water-lift? Yes, principally.

Windmills. 5471. Have you used windmills? I have no faith in them unless there is a reservoir to hold about a week's supply of water. I have used them for gardens. I found that you require a week's supply.

Tanks. 5472. What guided you in selecting the positions of your tanks? We go between red and black soil country.

Drains. 5473. Have you excavated drains to these tanks? Yes, in some instances a mile and a half; we have main drains and small feeders. The main drains are made with a plough and scoop; the small ones are ploughed, and the loose earth is afterwards shovelled out.

New Land Act. 5474. Do you think that the provisions of the new Land Act will be conducive to making further improvements? No; because the improvements have to be handed over at the end of the lease without compensation, otherwise there would be a great deal more water conservation.

5475. Do you not consider that you have sufficient security under the Act? The inducements to improve are lessened so much by the provision to which I refer that people will not do more than they feel they are absolutely obliged to do in order to utilize the country, otherwise I think private enterprise would afford an abundant supply of water for bad times.

Cato Creek. 5476. You know the Cato Creek? Yes.

5477. Is there any permanent water in it now? There are several waterholes.

Length. 5478. What is the length of its course from the Barwon into the Bokhara? About 25 miles.

5479. But by following the bends of the river? I should say quite 40 miles.

Channel. 5480. And the channel, is it as large and deep as those of the Bokhara and Barwon? It is a great deal wider and deeper than the channel of the Bokhara; it is almost as wide as that of the Barwon, and fully half as deep.

Width and depth. 5481. What is the average width and depth? It is about 150 feet wide, and the depth would be about 20 feet.

Dams. 5482. Would there be any difficulty in damming it where it enters the Bokhara? There is a place 3 miles east of the junction where that could be easily done. There is a rocky bar there which already forms a dam of 3 or 4 feet.

5483. Is that like the Fisheries here? Yes, on a smaller scale.

5484. Have you any dam on that creek? No.

Rocky bar. 5485. Would they be of any use in conserving water for the run? Yes; the rocky bar I speak of is on a reserve, or something would have been done with it before now.

5486. You think then that a large body of water could be conserved in that creek? Yes, easily.

5487. What dam would you recommend? Stone and cement overshot.

Tarrion Creek. 5488. Do you know the Tarrion Creek? Yes.

5489. It is similar to the Cato? Yes; but it requires a much higher flood in the Barwon to cause it to run.

5490. Can you say what height the Barwon would have to be above the present level in order to cause the Cato to run? About 15 feet.

5491. Could the Tarrion Creek be made use of in the same way as the Cato for the conservation of a large body of water? Not to the same extent; because at the upper end there is a great flat piece of country, and 6 or 8 miles below that it bends out again. There are 8 miles of well-defined creek that could be treated in that way.

The bar. 5492. What height is the body of the Tarrion above the body of the Cato? I do not know; the bar is almost 30 feet above the summer level of the Barwon.

Expenditure on water conservation. 5493. *Chairman.*] What proportion of expenditure in the management of a large station like yours would be set aside for water conservation as an annual expense? During the four years we have been on the place our expenditure under that head has been about £3,000 annually. I do not think it would average that by a very long way.

Water rate. 5494. Considering the large expenditure for water conservation and the possible loss by partial failure, what amount of money do you think the pastoral tenants would voluntarily pay for a constant supply on their stations? I think they would willingly join in the work.

5495. *Mr. McMordie.*] Would the people who benefited be willing to pay a rate sufficient to cover the interest on the expenditure, and to form a small sinking fund with which to extinguish the cost of the works? I believe they would.

Trusts. 5496. Under what form of management should these works be put? I think they should be managed by Local Trusts, and the works might be divided into districts, and be supervised by a resident officer appointed by the Local Trusts.

Benefits. 5497. You think that a provision well thought out for the conservation of water in these rivers would be of general benefit to the whole of the back country? I do, assuredly.

5498. And you think that your opinion would be supported by evidence in this district? Yes. All the residents I know of who have discussed the matter with me entertain views pretty much the same as my own.

Weir. 5499. *Mr. Donkin.*] Is it possible, when a foundation can be obtained, to put a weir across the Darling? Yes, wherever you find the rocks.

The Fisheries. 5500. What is the height of the natural weir at the Fisheries? About 8 feet.

5501. Has it been tested? Yes, but I cannot remember who did it.

5502. Is the river now at its ordinary summer level? Yes.

5503. How far at the present level does the weir throw the water back? To somewhere near the Boorooma boundary, about 30 miles from here.

5504.

5504. Do you think that the putting of such weirs across the Darling would induce channels to cut up on either side, such as the Cato and Tarrion Creeks? Not as long as you have an overshot and low-crested weir. Mr. J. Henderson. 19 May, 1885.

5505. Do you think that the present weir has anything to do with the formation of these natural channels? No, I do not think so.

WEDNESDAY, 20 *MAY*, 1885.

At Brewarrina.

Present:—

MR. BARTON, M.P.,
MR. DONKIN, J.P.,
MR. FRANKLIN, C.E.,
MR. M'MORDIE, M.I.C.E.

F. A. FRANKLIN, ESQ., C.E., IN THE CHAIR.

Mr. Richard James Kelly called in and examined:—

5506. *Chairman.*] How long have you been a resident in this district? In the Bourke district for twenty-two years. Mr. R. J. Kelly. 20 May, 1885.

5507. Are you well acquainted with the country all around Brewarrina and Bourke? Yes, I have a fair knowledge of it.

5508. How far does your knowledge extend from Brewarrina to the eastward and to the westward? I have been about 40 miles below Bourke, to Gundabooka and the boundary of the district of Cowper, and eastward as far as Boorooma.

5509. Of late years you are aware that the country has suffered great losses of stock? Yes. Loss of stock.

5510. To what do you mainly attribute that loss? I attribute it to the scarcity of food and deficiency of water.

5511. At what rate do you think the loss has been, taking a general average, within the radius you have mentioned? I cannot exactly say; it has been heavier in some parts than it has been here; the general average in the district of Brewarrina has been about two-thirds.

5512. Have you known any great scarcity of water in the Barwon River, on the frontage between Boorooma and Brewarrina? In some places there has been a scarcity of water in the river itself. The Barwon.

5513. You have personal experience of the drought as a selector on the Tarrion Creek? Yes.

5514. What is the area of your selection? 640 acres. Area of selection.

5515. Is it situated on the banks of the creek? Yes. Situation.

5516. How has the creek been generally during the time of your occupation? We have had water, but it has been very low lately. Tarrion Creek.

5517. Is the creek supplied by back-water from the Barwon? It runs out from the Barwon; it is on the south side of the Barwon, the same as the Cato.

5518. At a point how far east of Brewarrina does the water enter Tarrion Creek? About 30 miles.

5519. What is the extent of Tarrion Creek from the river? It empties itself into the Bogan—about 40 miles.

5520. What is the nature of the creek—is it deep with steep banks? In some places it is very deep, and in others very shallow. Banks.

5521. What is its course—is it very tortuous, or does it run straight? It is in the form of a circle; it winds very much in its course. Course

5522. Have you seen the creek in times of flood? I have. Flood.

5523. Is there a great velocity of water in the river at the time of discharge? Yes, there is a great fall. Velocity.

5524. Has any attempt been made to dam any portion of the creek? Yes, there is a dam over it now. Dam

5525. Where is that situated? About a mile from the crossing to Byrock, on a run called Charlton. Position.

5526. What is the nature of the dam? It is simply an earthwork dam; I may state that when the dam was first erected it threw the water back 10 miles. Dam

5527. What is the height of the dam? About 24 feet. Height.

5528. Is it placed up to the level of the natural banks of the creek? Higher.

5529. Are wings carried out from the top of the dam into the sides? Only to a small extent. Wings.

5530. What is the effect of the obstruction of the water on the surrounding land? It floods a great deal of it; in times of flood, on account of the dam, the mails have to go 5 miles higher up. Effect.

5531. You say that the dam withstood the pressure of a flood? I think that it has done so.

5532. What was the effect on the dam? The dam stood it.

5533. Did the wings suffer? They suffered considerably, but the top portion of the dam stood it very well.

5534. What was the object of building the dam so high—would not an overshot dam have been better? We did not know as much about the matter then as we do now.

5535. How long ago was the dam built? Twelve years.

5536. Is it still in existence? Yes.

5537. And it has served its purpose several times? Yes.

5538. How long does the water which is thrown back last? In one case it was permanent for three years. Permanency of water

5539. It was never exhausted? No; there is water there now which is the remnant of the last flood.

5540. When the dam was erected, was any objection raised by the people below? They objected to be cut off from water at the lower end, but few persons were interested; the chief persons interested were the Brewarrina people. Objections.

5541. Were any measures adopted to convey the water beyond the wings by any watercourse into the creek again? No.

5542. Would not that have given a quick discharge into the lower part of the creek? I think so. Discharge.

5543. I suppose that when the creek is in fair flood the obstruction of the dam would be a small item in the obstruction of water sent down? It would make very little difference.

5543½. It is only in small floods that the people would suffer? Yes.

5544.

Mr. R. J. Kelly. 20 May, 1885.

5544. Do you think that if a dam were placed in such a creek with means provided for the discharge of water to the lower parts of the creek in proportionate quantities that any objection would be taken? I think not.

Series of dams. 5545. Do you think that the placing of a series of dams on the length of the creek at intervals would be beneficial to the district? Yes; I think it is one of the best creeks in the district for that purpose.

5546. If that one creek were so treated, what extent of country would be benefited on its line? It would give about 40 miles of water-frontage.

The Birrie. 5547. Do you know of any other creeks in the neighbourhood which could be treated in a similar way with similar results? I know of a number of creeks, but I have had no experience of them; I know the Birrie, for instance; I have seen them all in flood, but I have no special knowledge of them; there is any amount of water in them.

Dams. 5548. What description of dams are erected on the Bokhara? Earthwork.

5549. You do not know of a timber one on Mr. Henderson's run? No.

The Cato. 5550. You know the Cato Creek? Yes.

5551. Is that a very large opening? Yes.

Storage capacity. 5552. There would be a large storage capacity for water if it were retained? Yes.

5553. Do you know its inlet from the river? I do not.

5554. As far as you remember, would it be a work of great magnitude to enclose it with a dam? I do not think so.

The Barwon. 5555. Do you know of any part of the Barwon which might be treated for a low-level dam? Yes; I think the rocks above Boorooma might be so treated.

Rocks. 5556. What is the nature of the rocks—are they visible on the banks of the river? Yes, I think so.

5557. Is there a large quantity of stone in that vicinity which might be obtained for the erection of a weir? Yes.

Country. 5558. What is the nature of the country about that position—does it seem to fall away to the river and offer a line for drainage? It appears to be level.

Weir. 5559. You have seen the weir close to the town? Yes; it is a natural weir.

Sluices. 5560. But the arrangement of sluices is artificial? It is the work of the blacks.

5561. The result of that obstruction is to raise the water-level of the Barwon above? Yes.

Fall. 5562. To what height? The fall would be about 8 feet.

Effect. 5563. Without that obstruction, would not the river at some times during your experience have been quite dry? I think that it would have been.

5564. But it never has been? There is always any amount of water above and below; I have seen the river dry at the crossing-place.

5565. So that this natural weir has been the means of providing you with a permanent supply of water? I consider so.

5566. Do you think that a succession of weirs on the river of the same proportionate height would have the same effect throughout its length? I do.

5567. And that it would not materially interfere with the general flow of freshets and floods? If it were a heavy flood it would throw the water back.

Erosion. 5568. Would it have the effect of eroding the banks at the site of the obstruction? I do not think so.

5569. Is that your opinion, or have you heard it stated that this natural obstruction here was the cause of opening any creeks above it within a distance of 8 or 10 miles? Not to my knowledge.

5570. You are not aware of any damage having been done to the banks above this obstruction? No.

5571. It has never, within your knowledge, shown a tendency to disturb the original formation of the banks at its own site? No.

Bars for weirs. 5572. Do you know of any position below Brewarrina towards Bourke which would be suited to the same treatment in the way of weirs? I know of one about 20 miles from here, between Beemery and Bourke; they call it Vincent's Old Crossing.

5573. What is the nature of that crossing? A stony bar.

5574. Is the river copious at a point above it? Yes.

5575. Suppose a weir were raised at that point 8 or 10 feet high, how much back-water would it give? 10 feet would throw it back about 7 miles.

Culgoa. 5576. Do you know the county of Culgoa? I do not know much about it.

5577. Have you been towards the border in that direction? I have.

5578. Did you come across any creeks there? I have seen swampy ground there.

Country. 5579. What is the nature of the country? It is generally flat, but there are some rises.

5580. In what direction does the water flow? Towards the Culgoa.

Creeks. 5581. You do not know of any established creek of any magnitude as far as you went? The Culgoa itself is the only one which I know of.

Settlement. 5582. Is that pretty closely settled for pastoral purposes? Yes.

5583. In what way do they supply themselves with water? From the Culgoa.

5584. Generally, I suppose, stock is watered by tanks? I did not observe any; I was there in flood-time.

The Birrie. 5585. Are you aware that the Birrie discharges a great deal more water than the Bokhara—that the Birrie is frequently full of water when the Bokhara is empty? I do not think there is much difference.

5586. When one is supplied they have very little to complain of in the other? I do not think there is much difference; I have heard it stated that the Birrie takes a larger quantity of water.

5587. You are not aware that it is a more deeply depressed river in regard to level than the Bokhara or the Culgoa? Not that I am aware of.

5588. You have no personal experience of water in the Culgoa country? No.

Settlers. 5589. Do you know of any settlers between the boundaries of Gundabooka and the Culgoa? I know of one—Mr. Colless.

Permanent supply. 5590. Do you think that with close examination the natural waters might be so regulated as to keep up a permanent supply in the large district you have mentioned? I do.

Water rate. 5591. And if it were done successfully, under proper supervision, do you think that the people who would be benefited would be prepared to pay for the use of the water in any proportion to their loss of stock over a series of years? I believe that the majority would be inclined to do so.

5592. You think that they would voluntarily pay for the use of water which would avert the loss of stock? I think so.

5593.

Mr. R. J. Kelly. 20 May, 1885.

5593. Can you give us any information in connection with creeks and rivers at this point which would be useful to us, taking the whole system of the Culgoa and the main river? It has often struck me that if dams were put in the creeks at various points there would be a great saving of water.

Depressions.

5594. Do you know of any large billabong or natural depression on either side of the rivers named where the water enters at flood-time and recedes as the river recedes, leaving them dry? I do not remember any now.

5595. Do you know that such billabongs exist in large dimensions above this towards Walgett? I do.

5596. Do you think that they could be converted into reservoirs? I am sure they could; I know of several here, between here and Bourke, which would answer the same purpose.

5597. Where are they situated? After you leave Yambacoona, and before you get to Beemery, there are three big places.

Capacity.

5598. Are they very extensive? Very large; an enormous amount of water could be stored in them; I think that the supply could be made permanent.

Use.

5599. Do you think that if we found many such depressions in the banks of the rivers, they might be availed of in some manner so that the water stored might be beneficial at the time of extreme drought, by being discharged again into the bed of the river to keep it flowing? I think that it would be much better to keep it for the stock, allowing them to water themselves at the billabongs.

Constant flow in Darling.

5600. When the Darling and Barwon are very low, and become a series of waterholes, stagnant and boggy, do you not think that it would be a good thing to endeavour to keep up a constant steady flow of water in the beds of the rivers? Undoubtedly it would.

Watering back country.

5601. You are not aware that at the sites of these billabongs there are means whereby, by excavation, water could be carried into the back country by drainage works? It could be done quite easily.

5602. Then you recommend that closer examination of these places be made to ascertain that fact? Yes.

Flood-waters.

5603. How often have you seen the flood-waters of the Barwon enter Tarrion Creek? Four times in twenty years.

5604. On each occasion did the water remain sufficiently high to discharge water throughout the length of the creek? Yes, it flowed right through for weeks and weeks; we had it flowing for six weeks.

5605. Is your selection on Tarrion Creek above or below the dam on Charlton Station? On the upper side of the dam.

5606. You get the benefit of the water? Yes.

Length of creek.

5607. How far below your selection does the creek run out into flats? About 18 miles.

5608. That cannot be far off the Bogan? It is quite close to it; it must be in conflux with the Wet Bogan—the river proper.

Banks.

5609. Are there clearly defined banks all the way down? Yes.

5610. So that another dam could be erected if necessary? Yes.

Tarrion and Cato Creeks.

5611. What is the size and capacity of the Tarrion Creek, as compared with the Cato? It is superior to the Cato.

5612. Are the banks steeper? The Cato banks are steeper in one way, but the Tarrion is much wider.

5613. At what height does the Darling rise above summer level before it enters the Tarrion? I think it would have to rise 25 feet; the Cato runs long before the Tarrion.

Diversion into Tarrion Creek.

5614. Do you know of any site on the river banks above that point where an excavation could be made to discharge water at a lower level into the Tarrion? Yes; up towards the Marra water could be let into the Tarrion without any very great extent of work.

Velocity.

5615. Have you noticed whether there is a greater velocity of water at the entrance to the creek than there is lower down? Immediately on entering the creek the water runs faster.

Soil.

5616. What is the nature of the soil at the entrance to the creek? It is black soil.

5617. Is it friable? I think it could be deepened at very little expense.

5618. Have you noticed that after floods have subsided the off-take of the river has quickly become drier than the lower parts? Yes.

Bed.

5619. That indicates that the bottom of the creek is higher than the general bed lower down? Yes, much higher.

5620. *Mr. Donkin.*] What height above this weir would the river have to rise before discharging into the Cato? I think about 15 feet.

Diversion into Cato Creek.

5621. What would be the distance from the river to the Cato? I could not give you any idea; it would have to be a rise of 23 feet from the bed of the river at Brewarrina to flood the Cato.

5622. Do you know as a matter of fact the distance is 39½ miles? I did not know that; I should have said about 20 or 25 miles.

5623. Have you any means of knowing that what you state is correct by any gauge? I know from what I have heard from residents who have taken measurements in the rocks, and can form a good idea from these.

Gauge.

5624. You have no gauge in the river now? No.

Depth.

5625. What depth of water is there above the weir at the present level? I believe it will average from 15 to 20 feet.

5626. What is the greatest depth? In some places I think that it would be 25 feet.

Silt.

5627. Have you observed any great deposits of silt above the weir caused by floods? No; there is deep water at the back of the weir at the present time.

5628. There are no beds of silt? No.

5629. Is it shallower now than it was last summer? Yes, a long way; there is no comparison.

Flow of water.

5630. There is no opening in the weir to regulate the flow of water—to allow a rush of water through it? Not that I know of.

Length of weir.

5631. What is the length of the weir down stream? The bed of stone is about a quarter of a mile long.

5632. You do not know of any similar bar on the Darling? Not so extensive.

Lagoon.

5633. At Yambacoona, is not the bed of the lagoon almost as deep as the river itself? Yes; an immense body of water could be stored there.

5634. What is the length of it? As near as I can remember, it is about 3 miles around—it forms an island.

5635. *Mr. M'Mordie.*] Is there any marked difference in the times at which the Bokhara, the Birrie, and the Culgoa flow after rain? I could not say from my own knowledge.

Mr. R. J. Kelly. 20 May, 1885.

5636. Is there any cultivation of cereal crops in this district? Wheat and hay have been successfully grown at Gongolgin, but not by irrigation.

5637. If water were conserved in these creeks, would there be any extensive cultivation? I am sure there would be; I have tried irrigation on the red soil, and I found that the plants grew rapidly.

Crops. 5638. What would be the proportion of crops from irrigated land, as compared with crops from non-irrigated land? There would be an immense difference in favour of irrigation.

Effect of rain. 5639. What is the effect of 1 inch of rainfall over the general soil here? It would give us a good start—it would make the grass spring up several inches.

Irrigation. 5640. To what extent would irrigation be carried on if water were available—would it be carried on to the full extent of the supply available? I decidedly think so.

Water rate. 5641. Can you give us any information as to the rates per acre people would be willing to pay for water for irrigation? I could not say.

5642. What would it be worth? I could not say per acre.

5643. Do you think it would be worth £1 per acre per year? I think it would, especially in time of drought.

5644. *Mr. Donkin.*] As a matter of fact, people do not now use water for irrigation where they have it? No.

Selections. 5645. *Mr. M'Mordie.*] Without any works for the conservation of water in this district, are selections of any great value—could a man support a family on a selection in the present state of the country? In its present state he could; just now I consider we are having a first-class season; in ordinary seasons he could not live on it continuously; I speak from experience.

Settlement. 5646. If water were stored it would tend to increase settlement? Decidedly; it would be impossible for a man to live on 640 acres in this part of the country unless water were stored.

5647. *Mr. Donkin.*] You know that red soil, with water, will grow almost anything? It will.

5648. It is far preferable to the black soil? I have tried both, and I think the red the better.

Pink Hills. 5649. Are you acquainted with the route beyond the Pink Hills towards Byrock? I know that part of the country.

5650 How is it watered? Very badly.

Supply. 5651. Does it receive any supply from the Bogan? I do not think so; after you leave the Bogan you have no natural water.

5652. You do not know from any local floods or heavy rains in which direction water flows from the Bogan towards Byrock? If there are heavy rains the water would flow into the Bogan.

Places for storage. 5653. The road to Byrock is over dry country? Yes, but there are a number of places where water could be stored; there is a place where the Government now are constructing a dam for the conservation of water.

Byrock. 5654. The country between Byrock and the Pink Hills must be watered by tanks? Yes; there is no natural water from Pink Hills to Cobar, a distance of about 125 miles.

5655. Do you know that at Byrock there is a rock in which there is supposed to be water always? I have seen it dry, but very rarely; it could be made a great place for the storage of water.

5656. How far is that from the township? About 1¼ mile.

Mr. Colin Mackenzie called in and examined:—

Mr. C. Mackenzie. 20 May, 1885.

5657. *Chairman.*] You are a runholder here? Yes.

5658. Where is your run situated? On the Culgoa and the Birrie.

5659. What distance above the junction with the Barwon? About 50 miles.

5660. You have a water frontage on both the Culgoa and the Birrie? Yes, a double frontage.

5661. What is the extent of the run? 437,000 acres.

Area of run. 5662. What is the nature of the stock? Sheep at present. We had cattle, but they nearly all died.

Stock. 5663. What was the cause of the loss of the cattle? Dry seasons, and scarcity of grass and water.

Loss of cattle. 5664. In which particular do you suffer most? Mostly in regard to grass.

5665. Would a greater abundance of water have saved your stock? It would have saved a great many.

5666. During the past five years, have you suffered considerably from loss of stock? During the last three years our losses have been very great. During the two years previous we lost nothing.

5667. What is the distance on your run between the two frontages on your run? 10 miles.

5668. Have you any intermediate water? No.

5669. So that your stock can be on two frontages constantly? Yes.

Water supply. 5670. In which river do you find the most constant supply of water. The Birrie runs oftener than the Culgoa. When they both cease running there is not much difference between them. Weilmoringle is the head station, and Kiengal is the station on the Birrie.

Stock. 5671. What stock have you now? 40,000 sheep.

5672. Do you consider that you are fully stocked? No.

Season. 5673. Do you consider that this season is a good one? Not with us.

5674. Then the grass that we have here is somewhat local? Yes; it does not extend past Tullawanta.

The Birrie and the Culgoa. 5675. You say that the Birrie is more reliable for a water supply than the Culgoa? It runs some time when the Culgoa does not run at all.

5676. Can you give me any reason for it? There is a sandbar in the Culgoa where the rivers divide; that is in Queensland.

Dams. 5677. Have you made any effort to retain water in the Culgoa by dams? Not by permanent dams.

5678. But by temporary dams? Yes; when the river is low we generally put in two or three tail dams.

5679. To what height do you build these? We generally stop when they will hold 4 feet of water.

5680. What do you do to prevent it from rising more than 4 feet? We make the dam when the water is low, and when it rises 4 feet we put in another dam higher up to prevent the overflow; and if it is too high for us to hold we cut a channel round through the solid bank.

5681. You have never had your earthen dam washed away by the water? Yes, we have.

5682. What was the result? We lost the lot.

Nevine Creek. 5683. Is the Culgoa supplied by any other stream running through the county of Culgoa towards Queensland? The Nevine Creek joins the Culgoa on our run; it is called the Bourbon in our part of the country; it is known as the Nevine in Queensland.

5684. Is that a creek of any magnitude? It is a very fair creek a long way up. Mr. C. Mackenzie.
5685. How far have you been up? About 80 miles above our boundary, and there you can hardly trace it; it spreads out into a flat.
5686. When it joins with the Culgoa on your run it is a well-defined creek? Yes; all through our run it is a good creek. 20 May, 1885.
5687. Have you done anything towards locking the water on the Bourbon? We made a large dam, and had a splendid supply of water for one year, but the next year we had a flood which, in a few days cut a by-wash larger than the main creek—it made a new outlet. Dam on the Bourbon.
5688. Would that have been prevented if you had carried wings from your dams some distance on both sides? We had wings, but the natural overflow was not sufficient to carry all the water off, and it went over the wings. Wings.
5689. You think that a properly constructed weir would have received the pressure of the water? Yes. Weir.
5690. What was the height of the dam you raised there? Above 6 feet above the level of the bank. Height of dam.
5691. What was the depth of the creek? About 8 feet. Depth of creek.
5692. What back-water would that give you if it were naturally filled? About 9 miles straight behind the dam. Back water.
5693. You had that for a long time? For a year.
5694. Then the temporary dams that you made on the Culgoa would be below it? No; above it.
5695. And you do not know of any attempt being made on the Culgoa between that point and its discharge into the Barwon to obtain more permanent water? No. Works on the Culgoa.
5696. Are you acquainted with the overshot dams on the Birrie River? Yes, I have seen them. Overshot dams on the Birrie.
5697. How do they stand? They seem to be a great success—they stand well.
5698. They do not bring about the same result as that which you have mentioned; that is, they do not turn the water into a different channel? No.
5699. Do you know the details of construction? Yes. Construction.
5700. And you know them to be a great success? Yes. Success
5701. How many of them are there on the Birrie? Three. Number.
5702. And do they hold back a permanent supply of water? Yes. Supply.
5703. Does that give you the idea that the Birrie River is at a lower level than the Culgoa? The dams on the Birrie are not far apart, and they back the water up from one dam to another.
5704. Has the Bokhara been treated in the same way? No; it has been treated more harshly. They have earth dams all the way up—fourteen in all I think. The Bokhara.
5705. Have you any reason to believe that more water finds its way down the Birrie than down the Bokhara? Yes; I think the first obstruction on the Bokhara is too high, and throws the water back to the junction. Discharge.
5706. And by regulating the levels you think the discharge might be made equal down the two rivers? There is now a small bar at the mouth of the Bokhara about 18 inches higher than the new channel of the Birrie. There is silting between the upper dam and the bar which I have mentioned. Three or four dams on the Bokhara have been cut, and the water has been got right through.
5707. If the dams could be reduced on these two rivers by sluice opening, would that be a benefit? It would be to the Bokhara people, but not to the Birrie people. Sluice openings.
5708. If the water in the Birrie were regulated so as to fill the dams, would the balance discharge through the Bokhara be a loss or advantage to the other settlers? It would be a general advantage. Regulation of the Birrie.
5709. On your land on the Culgoa, what system do you adopt to water stock back from the river? We have tanks and wells. Stock watering.
5710. How far back into the country of Culgoa do you go? About 40 miles.
5711. How far back is your frontage line, for the occupation of stock, from the Culgoa waters? 5 miles back; then we have the Bourbon, which gives us (say) another 7 miles; then tanks.
5712. *Mr. Donkin.*] You know the whole course of the Bokhara? Yes.
5713. Is it longer than the Birrie? I do not think so; it is called the Birrie before the Bokhara breaks out. Course of the Bokhara.
5714. Is the Bokhara channel as deep and as large as that of the Birrie? No. Channel.
5715. Do you see any reason why the dam should not be put where the two rivers break out, so as to regulate the flood-waters? I think it would be hard on the residents down the Birrie. Flood-waters of the Birrie.
5716. Why should they have a larger supply than the residents down the Bokhara? The Birrie is a natural watercourse, and when our country is appraised we have to pay a higher rent for it. If the people had not put so much money into big dams on the Bokhara the water would have run through that river as often as it runs through the Birrie. Supply.
5717. The Bokhara waters more dry country than the Birrie? I do not think so; it goes through about the same extent of country. It is only 10 miles from the Bokhara to the Narran. The Bokhara and Birrie.
5718. Has the Birrie run this season for several months when there was no water in the Bokhara? It has. The Bokhara ran at the top end, but not lower.
5719. Has the Birrie run right through? It has, but it is not running at present.
5720. Has there been waste water in the Birrie? Yes.
5721. Is the Culgoa a secondary channel to the Birrie? Yes.
5722. And has the Culgoa been running through? Yes.
5723. Overflowing to the Barwon? Yes. The Culgoa.
5724. Do you know the Narran? A little; I have been on it several times, but I have not lived on it. The Narran.
5725. How does it compare with the Bokhara and the Birrie, as regards channel? It is larger than the Bokhara, but not so large as the Birrie.
5726. There is no objection on that river to the water being stopped? Not that I have heard of.
5727. Does it run out of the Ballanne? Yes, a long way up.
5728. *Chairman.*] Would it be possible to tap the waters of the Narran at the top of the lake and take them across the country to the Bokhara? I hardly think so. Diversion from the Narran.
5729. What is the nature of the country? Very flat boggy country upon the plains. Country.
5730. Are there any small creeks in this country discharging into the Bokhara? Not till you get below the lake. Creeks.
5731. But it shows that the drainage level would be somewhere in that direction? Yes.
5732. Do you think it would be worth examination in the way of levels? I do not think you would get enough water down the Narran to do any good. Levels.
5733. But enough water comes down the Narran to fill the large lake? Only sometimes. Supply.

Mr. C. Mackenzie. 20 May, 1885.

5734. But does it not also flood the land towards the river? Yes, but very seldom; I have seen it only once.

5735. How many tanks have you on your run in the county of Culgoa? We have only three at present.

5736. What is their dimensions in cubic yards? Some of them about 7,000, and the others are small, about 4,000 or 5,000 yards.

Tanks.

5737. What sites do you select in sinking these tanks? I generally get on to some hard plain of red soil. In that country we have some good clay-pans.

Depth.

5738. What is the most reliable depth? I think we go down to almost any depth you like.

5739. What is the depth you prefer in order to prevent evaporation? About 15 feet. I have not had much experience in tanks yet. The tanks are now filled for the first time. It is the first rain we have had since we put them down.

Wells.

5740. Have you had greater experience in wells in that part of the country? I hardly know whether you call them wells or springs. The deepest point at which we have obtained water is 23 feet, and the lowest is 3 feet.

5741. Speaking of them as springs, do you find the water rising to the surface as indicating the place where you should sink? Some of the wells, after they have been opened out, run over the surface.

5742. You have not tried the tube down in one of those places? No.

Supply.

5743. Having obtained water in this position, is it permanent? Yes.

Quality.

5744. Perfectly pure? Splendid water.

Supply

5745. Do you think it is local soakage? No, I think it must be springs; the supply never seems to alter in the driest season.

Strata.

5746. Do the wells on this station cost down? No; we sink in the solid rock.

5747. When you have touched the water, does it immediately flow into the excavation? Yes.

5748. How deep do you sink afterwards? The lowest we have gone down after striking water is 14 feet.

5749. And you were able to bale during the progress of the sinking? Yes.

Supply.

5750. Would that indicate the quantity of water you received into the well afterwards? Yes.

5751. Then you could pump your wells dry? Yes.

Size.

5752. What is the size of the wells? About 8 feet by 4 feet would be the average, 32 cubic feet to the foot.

5753. Do you ever find the well fail you? Never.

Supply.

5754. And do you think you could get an unlimited supply from the same source? We can only get that supply in about 4 miles of country—that is to say, 4 miles square.

Salt water.

5755. Have you any other kind of well? We have put down other wells, but we have always struck salt water.

5756. Did you ever attempt to get through the salt water? No.

5757. Have you had boring-machines on any part of your run? No.

Water supply improvement.

5758. Can you give us any other general information or suggestion for the improvement of the water supply in this part of the county of Culgoa? I may mention that near the boundary there is a small warrambool on the western bank of the Culgoa. In times of flood a slit cut from the end of the warrambool would convey water into the Nevine, and it would give a good supply of water for a considerable distance.

The Bourbon.

5759. Under other circumstances it is very dry in that part of the country? Yes; the Bourbon is a fine creek, but it very seldom runs; it is much better than the Culgoa, the Birrie, or the Narran, when the holes get filled.

5760. Would it be possible to close the Bourbon by one or two dams in its whole length? Yes; that is by putting down dams you would retain water. It would be a very great benefit.

Storage.

5761. As far as you know this creek, you think that if the water was held at a time of flood, it would remain for a considerable time and form a supply? Yes.

Soil.

5762. The ground is retentive? Yes.

Expenditure on water supply.

5763. In the management of so large a station as yours, what proportion of expenditure would be necessarily considered as set aside for water conservation? I could not give you any idea yet. I have only been among sheep for the last two years. A permanent supply ought to be worth about 15 per cent. on the general management.

5764. What would the general management expenses of the station be if it were fully stocked? About £10,000 a year.

Water-rate.

5765. If water could be supplied to the runholder, and if Trusts were formed for the management of water-works, do you think the lessees would pay a rate for the water? I think they would.

5766. The rate you name would pay interest on a large sum of money? Yes, it would. Perhaps I have given it a little too high.

Trusts.

5767. Suppose these works could be undertaken all over the country, and the country were divided into districts, you think the management of the work would be better in the hands of local Trusts? I think that if private people had the necessary legislation they would be willing to make their own dams.

Legislation.

5768. On what grounds do you think so? If you put up a dam you are liable to have it cut.

5769. You only want to be protected? Yes.

5770. And is the cutting of a dam the only thing you would fear? I suppose that under the new Land Law it would be the only thing to fear.

Tenure.

5771. If you had a more secure tenure you would make greater improvements? Yes.

5772. *Mr. Donkin.*] Had the people whose dams were cut on the Bokhara any redress? No.

5773. *Chairman.*] Perhaps under proper supervision no dams would have been placed there? I think not. On one occasion last year I myself helped to cut a dam on the Birrie. You mentioned boring-machines just now: I may say that a neighbour of mine has a machine at work; it is on the western side towards the Warrego River; Moulton Plains is the name of the station; they are down 128 feet, but have so far struck no water.

Boring-machines.

Strata.

5774. Do you know what strata they are passing through? I believe it is blue rock. It is a Wright and Edwards drill.

Tanks.

Well.

5775. Do you know what they are doing in other places for water—on the western boundary of your run? Most of the water they have is in tanks constructed similarly to my own. We have a well on the boundary, and they put down another well about 12 feet off. They went down 93 feet and got no water at all. We got water at 8 feet. The boundary line goes through the well.

5776. Is there much interest felt in this part of the country in efforts to conserve water? I have heard a great deal of it during the last three months.

5777.

5777. You think that these natural advantages, which we have seen day after day, have been well known to the lessees, but they could no avail themselves of them for the reasons you have stated? Yes. Mr. C. Mackenzie.

5778. They were perfectly well aware that they had these storing grounds, but they would not go to any expense under their former tenure? That had something to do with it, but I suppose there were other reasons. 20 May, 1885.

Mr. Evelyn Manning called in and examined:—

5779. *Chairman.*] What is the length of your experience in this district? Three and a half years. Mr. E. Manning.

5780. Concerning what radius of country, taking Brewarrina as the centre, can you give us information? I know Bokhara and the Birrie well; I also know the Bogan and the Marra. 20 May, 1885.

5781. How far down the Bogan do you know? About 80 miles down. The Bogan.

5782. You know the Bokhara well? I know it better than any other of the rivers. The Bokhara.

5783. It is generally stated that the Birrie River gives a better supply? The channel is a little lower. I have not ascertained it by level. The natural channel of the Birrie is a little lower. The Birrie.

5784. Do you know the nature of the country at the junction of the Bokhara with the Birrie? I do not know the actual character of the country there. Country.

5785. You know that they have made efforts on the Birrie to retain water by dam? Yes, small dams—overshots principally. Dams.

5786. Have you seen them? I have seen the best of them.

5787. Where is that? At Talawanta Station; it acts very well indeed.

5788. How many times have you known it to be entirely submerged by flood-waters? It was put up just before the drought; I think only twice. Submersion.

5789. Did you see the condition of the banks after the floods? No; I went to have a good look at the dam when it was just finished. Banks.

5790. You do not know then whether any disturbance of the bank took place? I do not think so.

5791. Are the banks like the banks of the river? No, the banks are very different; they are low banks, comparatively speaking.

5792. Is the material the same—is it likely to erode? The site was not selected on account of there being a harder material. The dams are placed at very narrow spots. All that they care about is the getting of the dam at the narrowest place, so as to cheapen the cost of construction. Position of dam.

5793. Do you know whether the people on the adjoining station object to this dam on the ground of overflow? I never heard of an overflow from one of the overshot dams. They are quite different from the earthen dams. Objections.

5794. They throw the water back a considerable distance? The Talawanta dam throws the water back 6 or 7 miles, if I recollect rightly. Back-water.

5795. It makes comparatively permanent water? Yes. Permanency.

5796. And, as far as you know, it is altogether a great advantage? Not only to the station itself, but to the station below. Advantage.

5797. In this flat country, where the creeks are so numerous, might not that principle be adopted on a very large scale? That is so. In my opinion it is the best means of conserving water for stock. I believe that a succession of overshot dams is the proper method of conserving the water in these creeks. An earthen dam is too large, and some of the water escapes over the country. The overshot dam keeps the water in its natural channel. Water conservation. Overshot dams.

5798. Do you know that they have placed earthen dams on the Bokhara, and that for their safety they have placed them higher than the banks of the creek? You must do that in the case of earthen dams, because if the water flows over the top the dam is carried away immediately. Construction.

5799. What is the result of building the dams in this fashion? As soon as the dam is filled the water spreads over the country, and eventually forms a new channel leading back into the river lower down the stream. A site is generally chosen where some natural channel exists. Results. Site.

5800. Do you know of any case in which the direction of a river has been changed by one of these obstructions? That took place on the Birrie at one point; there was a large earthen dam on the Milroy Run. The first flood cut a channel round it as large as the creek itself, and they had to make a dam in that also. Effect of obstruction.

5801. And in that case, had they adopted an overshot dam the channel would not have been disturbed? No. Overshot dams.

5802. The result would have been a good supply of permanent water? Yes. I think that in the worst of droughts the overshot dams would contain a certain amount of water, and would keep the beds of the creeks moist. They would thus prevent those great cracks which must otherwise occur. When a fresh comes down, it has not only to supply the channel but to pour millions of gallons down these huge cracks. Cracks.

5803. You have seen several floods? Yes, in the back creeks. I have seen only one flood in the Barwon. I have seen a couple of 30 feet rises in it, but they do not call that a flood here. Floods.

5804. Does that fill the Cato? About a 16 feet rise fills the Cato. The Cato.

5805. How far does it back up the Bokhara? That is more than I can say. Back-water.

5806. On the subsidence of the flood the Cato and the other creeks come back into the river? Yes; it is merely a billabong.

5807. You do not know of any effort being made to impound water in that creek? No. Impounding.

5808. And do you think it would be practicable? Yes, an enormous amount of water could be retained. The Cato has a fall from its mouth.

5809. The 30 feet rise in the river would give a 15 feet rise in the creek? Yes, more; because the bed of the river is lower than the entrance.

5810. Is there a bar at the entrance higher than the general bed of the creek? That is the case in all these lagoons. Bar.

5811. Do you know of any billabongs in the immediate neighbourhood of Brewarrina? There is the Tarrion, which runs out into flat. Billabongs. The Tarrion.

5812. There is a considerable body of water sent down there? Yes, but it requires a big flood to flood that creek. I do not know exactly where the Tarrion comes out—I think it is very nearly opposite the Cato. Supply.

5813. Would it be possible to deal with the Tarrion, as long as it remains a creek, so as to divert the flow over dry country? You could take it round the ridges into the flat country. It requires a high flood to fill the Tarrion—a flood which occurs only occasionally, say once in five years. Diversion.

5814. Supposing the water could be raised to the level of the Tarrion? I do not think you could do that. You could of course deepen the channel of the Tarrion.

5815.

Mr. E. Manning.

20 May, 1885.

Water conservation and irrigation.

5815. Is there not a bar there similar to that which is to be found on the Cato? No; it is a different sort of entrance; it does not come straight out of the bank—it flows round into a large flat, and afterwards forms into the creek.

5816. You think that the whole of this system of rivers is worthy our attention and examination, with a view to see in what manner they may be regulated, and by what means water may be retained? I do not believe you can irrigate the country out of them—there is not sufficient water coming down. As regards conservation, the only method would be by damming, either with earthen or overshot dams. The earthen dams would cause endless disturbance—there is always some fuss about these dams on these rivers. I think the immense volume of water which discharges into the Barwon could be retained by overshot dams, at least until the bed of the creek was filled. The surplus must of course escape.

The Marra. 5817. The Marra runs southerly from Collawarroy? Yes.

5818. Is it a well-defined creek? Yes.

Sectional area. 5819. What is the sectional area at the mouth? The banks would be about 15 feet high. It would be nearly 40 yards wide. It has a well-defined course. Generally on one side the banks rise straight, and on the other it is comparatively flat.

Floods. Discharge. 5820. At times of flood the waters of the Barwon would back into that creek, but with heavy local rains it would discharge freely into the Barwon? The Marra is the main channel of the Macquarie; it comes out of the Marshes.

Dams. 5821. Has anything been done in the way of damming on the Marra? Yes; there are earthen dams throughout.

Objections. 5822. And the same objection arose in regard to those dams as in regard to the dams on the Bokhara? Yes.

Effects. 5823. But they do retain water? Yes; you may say that they make it permanent.

Supply. 5824. And is the supply from the Macquarie Marshes sufficient to keep the dams full without causing any injury to the owners lower down? It has not run down for three years.

Sluices. 5825. And do you think that a more equitable arrangement for supply could be made if sluices were fixed in properly constructed dams? I think so. I think a succession of overshot dams would do all that is necessary. The place is particularly well suited to overshot dams; excellent sites could be found; within every mile you could find a suitable place.

Wings. By-washes. 5826. And the result of a perfect obstruction is to throw the water out into broad wings? They select places where a by-wash exists, and the water again finds its way into the river at a point lower down. The country is not so low as in the case of the creeks north of the Barwon; the out-spread is therefore not so great as in the Bokhara, &c.

5827. In undiminished quantity? Yes; I do not know of any case on the Marra where there is a long get-away.

Supply. 5828. If there were a fair supply coming down the Marra, and overshot dams were placed there, they would afford enough water for a permanent supply, and would give general satisfaction? I think so.

Dams on the Bokhara. 5829. Can you give us any other information? Only as to the Bokhara. If overshot dams were placed there I think all the bickering would cease, and that the stations would be just as well off as they are now.

Silt. The silt behind the first dam on the Bokhara has so raised the bed as to give an inordinate discharge into the Birie. The dams at the head of the Bokhara are very small.

5830. *Mr. M'Mordie.*] But they obstruct more water than overshot dams? Yes, of course, but the people do not consider that they are sufficiently close to the Birrie to warrant them in abstaining from that kind of

Site of dams. dam. My idea is that the dams should not be placed so close to the junction.

5831. If the first dam were put into the Bokhara under proper supervision we should get an equal supply, and the silting would not take place? Quite so.

Silt. 5832. Does much silting take place on the Marra Creek? I do not think so. It is all red soil. There is a good hard red bank.

Macquarie waters. 5833. No doubt in time of flood the Macquarie waters would find an uninterrupted course through the Marra Creek into the Barwon? Undoubtedly.

Cross-section. 5834. Have you ever taken the cross-sections of the Marra Creek? Never.

Length of the Tarrion. 5835. Do you know the length of the Tarrion Creek? Between 40 and 50 miles, I think. The good banks extend for a comparatively short distance.

Questions. 5836. *Mr. Donkin.*] Have you received a list of questions from the Commission? No, I have not.

5837. Would you be prepared to answer these questions gratis? Yes; I can answer any questions of the kind you indicate without charge.

5838. I ask because most of the licensed surveyors think they ought to be paid for it? I do not.

Mr. Ross R. Doyle called in and examined:—

Mr. R. R. Doyle.

20 May, 1885.

5839. *Chairman.*] What is your run? Weilmoringa; I have an interest in it.

5840. You have frontages to the Birrie and the Culgoa? Yes.

5841. And there is a good stream? It would not last more than three or four months unless it was

The Culgoa. Tail dams. dammed. We have put in tail dams; they are earthen dams, and they do very well.

5842. To what height have you built them above the bed of the creek? 4 feet.

5843. Supposing the water threatened to top your dam, have you by-washes or other means of saving the dam? It has to go away, and we stop the end of the next freshet. We ought to have overshot dams, but we have not had them yet.

Overshot dams. Cost. 5844. Are there overshot dams on the river? Yes, there are some below our run; they are very successful. I believe they cost over £300 each.

Width. 5845. Of what width are they? I suppose about 40 yards. Of course they are earthen wings.

Position. 5846. Are these dams placed in a shallow part of the creek? No; between two high banks. The wings are on the top of the banks; those of the overshot dams are below.

5847. Do you think these dams are better structures, although they cost more than the earthen dams repeated? Yes; if you put an earthen dam in the Birrie you stop all the water.

Series of dams. 5848. Could it not be repeated in the form of steps, so as to keep a continuous line of permanent water? I do not see why it should not be done.

The Birrie and the Bokhara. 5849. Is it not a fact that the Birrie has a better supply of water than the Bokhara? In one place I think the Birrie is 18 inches higher than the Bokhara. I do not know how to account for it, except it is owing to the silting up of the Bokhara by the construction of dams. I think the channel of the Birrie has been deepened to some extent by the operations of the Bokhara—but it was always a little deeper. There are

only

only three or four dams on the Birrie, and there are fourteen dams on the Bokhara. The first of the dams on the Bokhara thrust a lot of water out of the channel, and it is lost by absorption in the soil. Mr. R. R. Doyle.

5850. Do you think that a careful examination should be made with a view to the equalization of the discharge? Yes. 20 May, 1885.

5851. In the general management of stations, what would be the proportion of cost for water conservation? I can hardly answer that question—I should only guess. You might have a station with a good frontage. Expenditure for water conservation.

5852. What would it cost to afford a permanent supply of water for a 10-mile block? I should say about £4,000; that is if it were dry country without a frontage.

5853. *Mr. Barton.*] And it would cost you 5 per cent. to keep your supply clear of silt? Yes, fully.

5854. *Chairman.*] In view of that large supply, it seems to me that the pastoral tenants would be willing to pay a fair amount of money for the supply if they could depend upon it—by gravitation, for instance? Yes. Water rate.

5855. Supposing a general scheme of water conservation were carried out, with proper supervision and guidance, do you think the pastoral tenants would submit to a charge in proportion to the advantage? I should think they would be very glad to do it.

5856. What system of government for these local works would you think the best—ought they to be carried out by Trusts? I do not believe very much in Trusts—they neglect their duties. Trusts.

5857. Do you think we should get better attention under local management than if the works were managed by a Board in Sydney? I should think so. I should think a paid local Board would be best.

5858. Is the Bourbon Creek a reliable creek? Fairly so. The Bourbon.

5859. Are there any dams there? There is an earthen dam, but the by-wash has all carried away. Dams.

5860. If an inexpensive dam were designed for such places it would be a constant source of supply? Yes. Supply.

5861. What is the outlet of the Bourbon Creek to the Culgoa—does it widen out at all? It is about 40 yards wide; and a dam about 2 miles up from the outlet would give a large supply in a very dry part of the country. Outlet.

5862. Do you know the nature of the country from Eringonia down to Colless's station? I know it is a very dry country for 40 miles from Eringonia. Country.

5863. Does the water come down towards the Culgoa? It would take a very high flood to do so. I know that water does run down by Featherstonhaugh in the direction of the Culgoa, and that it would be a good part of the country for the use of boring machines. There are springs there. Flow of water. Springs.

5864. Do you think that the waters of the Narran can be diverted into the Narran? There are water-courses in that direction. In times of high flood I think you could bring the water anywhere you like. The country is very flat, but the water does run in that direction sometimes. Diversion of the Narran.

5865. Do you use the springs you have referred to? We use them to water about 20,000 sheep. The stone is hard and flinty; it is strongly impregnated with soda. Supply from Springs.

5866. *Mr. Barton.*] Can you suggest anything in the way of legislation, in reference to dams, to prevent persons from monopolizing the whole of the water; I suppose you have seen the evils of that? I have. It takes a big flood to run down the Bokhara, in consequence of the large dams which have been placed there. Legislation.

5867. Would it be advisable to legislate to prevent any one person at the head of the rivers monopolizing the whole of the water and draining it off to waste? I think that will have to be done.

5868. *Chairman.*] Do you think a system of dams, provided with regulating sluices, would be advisable? I should think so; I suppose the stream can be carried on in that way. System of dams.

5869. You think that would meet the difficulty? Yes; even the ordinary overshot dams would do that. Matters are getting serious now, and people are beginning to cut each other's dams.

5870. And the efforts of the Government to cause an inquiry into water conservation is favourably viewed by the pastoral tenants? I think so. It is the general wish to have some legislation with regard to dams. I may put up a dam either overshot or earthen, and any one of my neighbours may come next day and blow it up with dynamite. Water conservation inquiry.

5871. And the runholders would do as much as they could do in the conservation of water if they had a fair tenure of their property? Of course they would do more if they had a fair tenure; but I suppose they will have a fair tenure now. Tenure.

5872. *Mr. M'Mordie.*] If a large supply of water were stored in these rivers and creeks, do you think it would to any considerable extent be used for the growth of crops? I think so, to a slight extent. Crops.

5873. Do you think it would increase settlement and induce people to select land and settle down on small areas? I think it would under the present law. Settlement.

5874. Is it possible that this dry country can support any considerable population under the present state of affairs? I do not think so; it would be a very precarious mode of life.

5875. What is the cause of it? Scarcity of water.

5876. Therefore, if water were made available by storing it the difficulty would be removed, and there would be a tendency to increased population? Certainly.

5877. *Chairman.*] Do you not find that owing to the sparse population you have great difficulty in getting sufficient hands in the wool season? No, not much; we have to pay high wages. Labour.

5878. And if men settled on small areas they would be available for that purpose? Decidedly; at present we get the scum of the earth out in this direction in the wool season.

Mr. George Colless called in and examined:—

5879. *Chairman.*] You have been resident in this district for some years? Since May, 1850; I have been for the greater part of that time in the district. Mr. G. Colless.

5880. Are you settled here as a pastoralist? At the present time I am a conditional purchaser; I used to hold a run of 45,000 acres on the Culgoa. 20 May, 1885.

5881. You have seen the district in conditions of drought and fair seasons for a long period? Yes; in 1850–51 we had the most severe drought I have known. Seasons.

5882. You have also seen the country under severe flood. Yes. Floods.

5883. What is the condition of the country generally on the Culgoa and Barwon and their tributaries after the subsidence of floods—is the country generally supplied with water for any length of time? The water-holes in the courses are supplied, but there is no water back, except in such cases as the Cato and the Tarrion. Water supply.

5884. Do those creeks retain water—supposing there was a flood attaining a very high level, would it leave a large quantity of water in the creeks? In the Culgoa it would, but in the Birrie and the Bokhara they have to retain the water. The Ballonne maintains sufficient supply for the Narran and other creeks. Creeks.

5885.

Mr. G. Colless. 20 May, 1885.

5885. Local rains at the head of that river would keep these four rivers constantly running? Yes.

5886. So that there is more permanent supply than in the Barwon and other rivers? There is no river here except the Barwon which has a constant supply.

Back-water.

5887. These rivers in flood throw a quantity of water back on either side? I have seen it from this place to my place, on the Culgoa, 30 miles under water; I have gone in a boat from my place to within 2 miles of the 12-mile ridge.

12-mile ridge.

5888. In which direction is that from the Culgoa? About north-west, on the Warrego Road; it crosses Featherstonhaugh's run.

Dry lake.

5889. Are there any large billabongs in the back-water, or is it generally shallow? There is a kind of dry lake; there is no great depth of water; I have seen it run from the Warrego to the Lednappa; that is the drainage line.

Drainage line.

5890. Is not that a very dry portion of the country? Very dry.

The Warrego.

5891. And you think that it is possible that that water might be turned across there to keep up a constant supply? The Warrego is not as good a creek as the Culgoa; it would benefit the country between, but not the Culgoa. If you could make a canal it would be a great benefit.

Storage.

5892. Do you know of any large billabongs on the Barwon where large quantities of water could be stored during flood-time? Between here and Walgett there are billabongs which would store immense quantities of water.

Supply in the Barwon.

5893. If we stored large bodies of water like that, would it be of any benefit at any time? I have never known the Barwon to be dry; I saw it as a chain of waterholes in 1850–51; the longest distance I ever saw between two holes was a mile.

Current.

5894. If the river could be kept continually flowing would it not be a great benefit? I do not know.

5895. Would not the water become stagnant in the waterholes? I have seldom known the river to stop running; if you could send a supply of water down the river occasionally it would be a great advantage.

Dams on the Bokhara.

5896. You know that on the Bokhara they have dams fixed? I do.

Irrigation.

5897. Are they what is wanted? They are not high enough; if they were carried high enough they would irrigate all the surrounding country; a dam placed on the Tarrion would irrigate miles of country.

5898. If the water could be raised in that creek a dam would intercept it and throw it over a large area of country? Yes.

Country between the Culgoa and the Warrego. Tanks.

5899. You know the country between Colless's station on the Culgoa and the Warrego? Yes.

5900. How is it generally watered? By tanks.

Supply.

5901. You know of no creeks? There are none that I know of.

5902. And the only possibility of supplementing the water in the tanks would be by conserving water in the Warrego and pouring it across by artificial works? Yes.

5903. Is the country favourable for such works? Yes.

Government tanks.

5904. What are the tanks on a line from Colless's Crossing to Eringonia? There is a Government tank at Lednappa on the reserve; that is 35 miles from Eringonia; it is a very large tank; there is a clay-pan all around it, and it catches water very quickly.

Expenditure on water conservation.

5905. I suppose that, in the management of a station property, it is estimated that a large sum of money must be set apart for the watering of stock? Yes.

5906. What proportion of the cost of management would you set apart for it; supposing you spent £1,000, would it cost £400 of that for water? I estimate that it would cost £500 out of every £1,000, or about 50 per cent. of the cost of management.

Water rate.

5907. Supposing all these creeks were so controlled as to give a constant supply of water for this large area, would the runholders willingly pay for the advantage? I think they ought to pay for it; they ought to be very well satisfied to do so.

Loss of stock.

5908. In addition to the ascertained cost of works for water supply there has been a considerable loss of stock? There has.

5909. Owing to the absence of water? Yes. In the dry country on the Darling it is owing to the absence of grass.

5910. So that in a great measure the loss of stock must be added to the cost of obtaining water as far as they have gone? Yes.

5911. I suppose you know that the squatters have assisted themselves in a great measure in supplying water for their stations? Yes.

5912. And you know that the works have been somewhat faulty for want of proper information as to how to proceed with them? I think so.

Scheme for water supply.

5913. And you think that a carefully devised scheme for the supply of water would be less expensive to the squatter than what they are furnishing at their own hands? Yes, because it would water country which is of no use to them at the present time. I may say that about 15 miles west of Colless's station there are

Mud springs.

seven or eight mud springs all in a cluster; the mud blows up into mounds, and it is all charged with water; if you were to get on to the mud you would sink down a considerable distance.

5914. How do they get water from these places? A stockman on Runnawanna went out and tried to put a shaft down; he boxed it, but the mud burst the boxes; when they left it over night the mud would rise up inside.

5915. They never tried to extract the water by tubes? No.

5916. Do they use the water in any way now? There is one place in which it can be used, but there is no great quantity; it is good water; there is always a small supply on the top of one of the hummocks, but it is of no use to any one.

Wells.

5917. Have they tried to sink wells in the neighbourhood of these mud springs? They have not; I intended to do so when I leased the land, but I sold it to Crosse and Featherstonhaugh; I believe that a well has been sunk at the saw-mill since I left the place, and that a fair supply of very good water has been obtained.

Dams on the Birrie.

5918. You have seen overshot dams on the Birrie? I have not; all the dams that I have seen made were on the top of the bank, and the water used to run around them and form a second creek.

Water conservation.

5919. Do you think that the people in this district would take a lively interest in any movement in the direction of water conservation? I do.

5920. And that they would support the Government in the matter? Decidedly; it would be to their benefit to do so, as where they carry a beast now they would carry ten if the country were irrigated—that is, if it were watered sufficiently for the growth of grass.

Station people.

5921. Are the people on the stations here generally principals or managers? Principals.

5922.

5922. You know they have made great efforts to assist themselves in the matter of water conservation wherever possible? Yes. Mr. G. Colless.

5923. Have they done so to the extent to which they might have gone? Not all. 20 May, 1885.

5924. Is there any particular reason why they should not do so? In many cases I fancy that they have not done so owing to the want of money.

5925. You think that they would not hesitate to spend more money if they could spare it for the purpose? I do not think they would.

5926. Have you any other general information which you think would be of service to the Commission? In most instances, on these rivers at all events, the back country is always lower than the country on the banks; I have noticed this. Fall of country.

5927. From that we may infer that cuttings made through the banks of the rivers would discharge water into the country behind? Yes. Diversion of water.

5928. Suppose we carried water through the banks of the rivers into the country beyond, would it be beneficial to use the water in that way? I think that it would be of the greatest benefit; I could mention many places which would be greatly benefited by it.

5929. Do you know of any creeks which by a little improvement could be made to convey water better than they do now? I do not think that it would be of much benefit, except in the case of the Barwon, and you do not want to shorten that. Improvements.

5930. *Mr. M'Mordie.*] If large quantities of water were stored in the rivers, creeks, and natural basins, would it be used to any great extent for the growth of crops? It could be used to great advantage in that way, but I do not think that it would be so used. Crops.

5931. Do you think that it would be profitably used? I do.

5932. In that case, do you think that selection, and therefore population, would be increased? No doubt they would. Population.

5933. And that the land would be made very much more valuable? It certainly would. Value of land.

5934. What would be the value of irrigated land, as compared with non-irrigated land? There is a great difference between the two; I should think that you could not grow a ton of hay on 100 acres now, but with irrigation you could grow what you liked.

5935. What would the water be worth for irrigation per acre per year? I do not know what other people would value it at; I should value it a great deal myself; I should not go in very largely for agriculture, but I should irrigate 100 acres if I could get the water, and I should not care much what I paid for it. Irrigation.

5936. Would it be worth £2 or 30s. per acre? It would not be worth £2; I do not know what they would do with produce in this part of the country; I would willingly pay £1 per acre, but I would not pay 30s.

5937. You think that it would increase settlement? It would if the land were properly irrigated; I think there is no doubt that there would be a large number of settlers in this part of the country. Settlement.

5938. Is it possible under the present state of affairs, in ordinary seasons, that this district can be populated? No.

5939. The country cannot be profitably occupied? Unless by squatters. With water it would support a large population. One year I had an acre of land under oats, and I got 3 tons of hay off it; that was in a favourable season; I have tried in other seasons since, but have not got anything.

5940. I suppose you know that on this river they are, by means of irrigation, growing a series of crops? Crops of pumpkins, cabbages, and potatoes are grown by Chinamen. Crops.

5941. You are sure that water is the agent required to produce payable results? It is.

5942. If such works as I have indicated were carried out, what system of management would be best for their maintenance, with a view to their being made to suit the requirements of the people in the districts? I should think that local Boards would be best; unless something is done to store the water the country cannot be occupied. Trusts.

Mr. Thomas Baird called in and examined:—

5943. *Chairman.*] You are a resident of Dubbo? Yes, about 2 miles out of Dubbo, on the opposite side of the Macquarie. Mr. T. Baird.

5944. Are you engaged in pastoral pursuits there? Yes. 20 May, 1885.

5945. I suppose you are well acquainted with the Macquarie River? Yes. The Macquarie.

5946. You have seen it in flood? Yes. Floods.

5947. And you know the results? Yes; I have seen it go all over the low country to the north of Dubbo, and all over the flats about the town.

5948. When the floods subside there, does the water run off very quickly? Yes.

5949. And the neighbouring creeks are well charged with water? Yes.

5950. You suffer no inconvenience in regard to stock? We have to be careful just about the angles of the river.

5951. What is the nature of the Talbragar? It is a very deep and wide creek. The Talbragar.

5952. I suppose the whole of the frontage to that creek is suited to pastoral and agricultural purposes? It is more adapted to agricultural than pastoral purposes. When you get up about 30 miles there is a really good agricultural district. Frontage.

5953. Have any measures been taken for the storing of water on that creek? No; it is very badly off in that way. Storage.

5954. Nothing has been done in the way of overshot dams? Not as far as I know. Dams.

5955. Is there any local objection to it? I do not know.

5956. Why have they not assisted themselves in that way? I suppose they have made dams on the back creeks and swamps.

5957. Does the creek discharge into the Macquarie? Yes; it is almost as deep as the Macquarie at the point of entrance. The water is sluggish in its discharge, and any obstruction in the shape of low-level dams is not likely to be removed by the velocity of the stream. Discharge current.

5958. How far would the water arrested by a weir go back? In some cases 7 or 8 miles. Back-water.

5959. You are aware that nothing of that sort has been done? Yes, nothing has been done.

5960. Could a system be devised for the shutting off of the water by overshot dams, and would it be beneficial for agricultural and other purposes? I think so. It is very dry country. You can get water by going down under the surface. Overshot dams. Underground supply.

5961.

Mr. T. Baird. 5961. Is the soil on the creeks retentive? No; it is rather of a sandy nature.

20 May, 1885. 5962. But you do not think that the flow of the creek arrested by steps would bring down any large quantity of silt? No; at the head of the Talbragar there are large waterholes in which there is no silt.

Silt. The silt is washed in from the surface drainage at intermediate places on the course.

5963. Do you think it would be deposited in such quantities as to nullify the advantage of the water? I should think so, in course of time; but it would take a long while.

5964. There are a great many tributaries to the Macquarie, and the information you have given would apply to most of these in level country? It would.

Height of banks. 5965. Do you think that from a succession of deposits in floods the banks have been raised above the back country on either side? I could not say. There are some very fine alluvial flats on the side of the Talbragar, but they have not been tested in regard to level.

Diversion. 5966. Could places be found on the banks from which, by the making of cuttings, water could be taken on to the back country? I believe such places could be found, but the plains are not very extensive.

5967. Higher up the creek there might be an increased declivity in the bed? Yes.

5968. And there we should get a head of water by gravitation to irrigate the plains below? Yes.

The Macquarie. 5969. Has any attempt been made on the main river of the Macquarie to dam or retain the water? No, I am sure not.

Fall. 5970. There is a small fall? Yes, after it passes Wellington.

Bars. 5971. You do not know of any natural obstruction existing in the river in the way of a bar of rock, or anything to indicate what would be the result of placing a dam across it? No; but there is a bar of rock about 30 miles below Dubbo, as the crow flies.

5972. Does it raise the water above the average level? You cannot see much difference.

Waterhole. 5973. Is there a pool of water above that obstruction? There is a waterhole.

Silt. 5974. It is not silted up? No; although in all waterholes on the Macquarie there are signs of silt.

5975. You know the course of the river to Warren? Yes.

5976. Do you know it as far as the Marshes? Yes.

Banks. 5977. How far does the river continue in deep banks towards the swamps? To about Growhay.

Waste in the swamp. 5978. In your opinion, is a great quantity of the Macquarie water wasted in the swamp? A great deal of it.

Value of country. 5979. Do you know the value of the country between the points mentioned, and from thence across to the Bogan? Yes.

Creeks. 5980. There are several creeks there? Yes.

Fall towards the Bogan. 5981. Is there any indication of a fall from the Macquarie to the Bogan? Yes; the water runs from the Macquarie all above Warren and goes into the Bogan.

Interception. 5982. Could you take a drainage line from the Macquarie to the Bogan and intercept the whole of these creeks? I think you might.

5983. By so doing we should put into an impermeable channel a great quantity of water now wasted in the Macquarie swamp? Yes.

5984. Do you think that the work would justify the Commission in making a closer examination in the way of levels? I think so—decidedly.

Nature of country. 5985. What is the nature of the country at this point on the Macquarie? There are good banks.

Diversion. 5986. And if a weir were made to resist the pressure of sudden flood the water could be diverted for useful purposes? Yes.

The Castlereagh. 5987. Do you know the Castlereagh? Yes.

Creeks. 5988. There are a number of creeks running between the Castlereagh and the Macquarie? Yes.

The Marshes. 5989. The Macquarie runs through the Marshes, but it is very ill defined? You would not know you were passing it. No one could swear to the main channel.

The Castlereagh. 5990. The Castlereagh is also a river of some importance: it seems to die out as it approaches the Barwon? It is a much better river to dam after it passes Coonamble than it is above, because the sand seems to cease there. From Coonamble down towards the Barwon there is the same flat country as that we have been speaking of, and it might be treated in the same way by overshot dams and weirs. I have no doubt that a dam placed across the Castlereagh above Coonamble would be very quickly silted.

Width. 5991. What is the average width of the Castlereagh above Coonamble? The average is considerably over 100 yards.

Depth. 5992. What would be the depth? In many places from 15 to 20 feet deep.

Water rate. 5993. Do you think that, if a properly devised scheme of water conservation were adopted, the agricultural and pastoral tenants would submit to the payment of a rate for water according to the quantity they required? I should think they ought to. Travelling stock can hardly pass at times for want of water.

Water conservation. 5994. Do the pastoral tenants now assist themselves in a great measure in the conservation of water? Yes, on the out creeks, away from the Castlereagh.

Dams. 5995. What means do they adopt? Earthen dams.

5996. But they are liable to be washed away? Yes.

5997. If a more permanent structure could be put in at an enhanced cost, would it not be better than these temporary works? Undoubtedly it would be much better.

Trusts. 5998. What system of supervision would you consider most practicable, supposing works of conservation were generally established—should they be managed by a Board in Sydney, or should there be local management? I should think local management, if there were good men, because they could soon be upon any spot to see what was required.

Crops. 5999. Is there much growth of cereals in your district? Not much; they have been at such a low price that the farmers have got sick of growing them. A great many grow hay, but they have not stored a large quantity. I think they are doing so more than formerly, especially with lucerne.

Irrigation. 6000. What is the result, as far as you know, of irrigation? It has yielded about 150 per cent. more than the same soil would yield in an ordinary season.

Legislation. 6001. *Mr. Barton.*] Do you think that there is a necessity for some legislation with reference to the damming of creeks and rivers? I think so. People are almost afraid to dam in many rivers lest their dams should be cut away; they say that if I preserve water my neighbours below will cut away the dam.

System of dams. 6002. Which do you consider the best system of dam, the earthen or the overshot? If you could get the overshot dams to stand I think they would be the best. My experience is that the water cuts round the ends.

ends. I have found the earthen dams the best, throwing the water off, and letting it find its way back again lower down into the main channel of the river. Mr. T. Baird.

6003. *Mr. M'Mordie.*] In the case of these large earthen dams which send the water over the country, is it not fair that the people below should have the right to cut them? If they all made dams they would all have water. There is always sufficient water coming down to supply the whole of the dams. 20 May, 1885. Supply of dams.

6004. If each dam drained water into the country 5 or 6 miles, would there be sufficient to supply the people at the lower end? Yes, because there are billabongs and swamps to bring the water back again into the main channel of the river.

6005. *Mr. Barton.*] And will not the floods occur more often as the country gets stocked and trodden down? Of course—there can be no doubt of it. The sheep pads harden the ground, and the cattle pads make natural channels to conduct the rains into the rivers. Frequency of floods.

6006. *Chairman.*] In legislating for continuous dams, would it not be an advantage if you could regulate the balance down the river? Yes.

SATURDAY, 23 *MAY*, 1885.

At Bourke.

Present:—

MR. BARTON, M.P., | MR. LYNE, M.P.,
MR. FRANKLIN, C.E., | MR. M'MORDIE, M.I.C.E.,
MR. MURRAY, M.P.

W. J. LYNE, Esq., M.P., PRESIDENT, IN THE CHAIR.

Mr. Charles S. Chauncy called in and examined:—

6007. *President.*] You are a licensed surveyor? Yes. Mr. C. S. Chauncy.

6008. How long have you been in this district? Getting on for four months.

6009. Where have you been employed during that time? In the county of Irrara. 23 May, 1885.

6010. Have you been making surveys there? Yes; measuring improvement purchases, dams, and tanks.

6011. Will you specify any dams? Yes; the best dams I have seen are those shown on this map. One is the Kirribie dam, in the county of Kirribie. There are tanks sunk on each side of it, and there have been between 11,000 and 12,000 yards of excavation on each side, above and below it. Dams.

6012. Above and below it in the creek? Yes.

6013. What is the effect of that in storing water? A dam about a mile below backs the water right up to it, and fills the tank on the lower side. Back-water.

6014. There is another dam—how far down? About a mile.

6015. And that dam backs the water up to the banks on the lower side of the upper dam? Yes.

6016. Then the country is very flat? Yes. Country.

6017. What is the fall? I could not say; I never tried. Fall.

6018. Is there a rock there? Yes, there are rocky sides—a kind of limestone. There is a by-wash on the southern side cut out of the rock. Rocks.

6019. Is there any rock in the bed of the creek? Yes.

6020. Is the dam built on rock? I could not say. It is full of water, but I think it is further down the creek. Where there is no water there are ridges of rock right across the creek.

6021. And are these places where ridges of rock go across generally selected as the sites of dams? Yes, as the creek is narrow there, of course the dams hold better. Sites of dams.

6022. What height is this dam? About 25 feet. There is over 20 feet of water in it. Height.

6023. But is it 25 feet higher than the bed of the creek or than the bottom of the bank? The bed of the creek.

6024. Then there must be some 20 feet of water if it is full? I do not know how near the excavation is to the dam, but I believe there is 20 feet in the dam without the excavation.

6025. Then it is not running over now? No, not at present, but it is full.

6026. What length of by-wash has it? About half a chain; it lies just over the bed of rock. By-wash.

6027. Where it falls off the rock into the creek, does it fall on to rock? Yes, on to rock; on a rocky bed right into the creek.

6028. Then there is no chance of wash? No; the dam is banked up to the by-wash with large boulders.

6029. Is that at the lower side? On the south wing,

6030. What length is the dam? It is about 2½ chains. Length of dam.

6031. What thickness? It is about 25 feet on the top, and it has a great batter. I do not know what it is at the bottom. Thickness.

6032. Is there more batter on the lower than on the upper side, or is it the same on each side? I think it is about the same. It is full of water, and I could not judge very well. Batter.

6033. Do you know whether it was made in the ordinary way by carting earth? Yes, I think so.

6034. There was no puddling? I do not think so. Puddling.

6035. How long has it been there? Since 1874. I think it was completed in 1875.

6036. And there have been heavy floods since? Yes.

6037. And has the dam ever given in any way? No. Solidity.

6038. Has there been permanent water? Yes.

6039. How far does it dam the water back? About 2½ miles. Back-water.

6040. Is the country level away from the creek? There is a very fair fall of perhaps 10 chains into the creek, and then it is quite level. Country.

6041. And what about the other dam below? There is more earthwork there, and I believe it is an almost equally good dam. It is a much longer dam; I should think it is 6 chains long. Longer dam.

6042. And how is the by-wash made? The by-wash is about 4 chains long, and runs over rock. By-wash.

6043. Do you know of any dam where the by-wash is not cut out of the rock? Yes; I know the Multagoona dam, on the Irrara Creek.

6044. Do these dams back the water from any ana-branches? No; there are no ana-branches.

6045. Are there any dams below the second one you spoke of? There is another one, but it is not of great importance, about a mile and a half further down. Other dam.

6046.

Mr. C. S. Chauncy. 23 May, 1885.

6046. Is that built in the same way? It is built in the same way, but it is much smaller.

6047. Is the by-wash through rock? I could not say. The by-wash runs out, but the soil is not washed away much; it has a stony bottom.

Width of water. 6048. What width of water is generally backed up by these dams—a broad or narrow sheet? The water is about 3 chains wide at the lower dam.

6049. And what about the upper dam? The water is about 3 chains wide there, and it gets narrower half a mile above the dam, and then opens out again into shallower and broader water.

Depth. 6050. About what depth is that shallower water? I should think about 10 feet deep. Between half a mile and a mile above the dam the water is shallower.

6051. What is the depth lower down? I believe it is from 15 to 20 feet close to the dam and within half a mile of it.

Rise. 6052. How near the top of the dam does the water rise? Within 6 feet.

6053. Is that the case in the two dams? In both of them; in the lower dam it may be only 5 feet when the water is full, and 6 feet in the upper dam; I noticed it particularly the other day.

Multagoona dam. 6054. What height is the Multagoona dam, the one with the by-wash of earth? It is 4 or 5 feet high; it is a very long dam, about 8 chains long.

Excavation. 6055. And is there an excavation above it? Yes; and the earth from the excavation is used for banking up the dam.

Depth. 6056. What depth is the excavation? I do not know; it was full of water and running over.

Thickness of dam. 6057. What thickness is the dam? I should think that on the top it is 5 or 6 feet.

Batter. 6058. And does it go away with a great batter? With a batter of one and a half to one.

By-wash. 6059. What sort of a by-wash is there? A very bad one; the water just runs round the end of the dam, and they have to keep repairing it, for fear the dam should wash away.

6060. Is the surface disturbed where the by-wash is, or does the water simply flow over the surface? It has been made to flow over the surface, and it has washed the earth into holes.

Channel. 6061. Has it made a channel? Yes.

Repairs. 6062. And how is it repaired after each flood? By throwing in more earth and bringing the channel further round.

6063. By lengthening the dam? Yes, as far as I could see, that is the way it has been done; there are two or three big trees with large roots which I think serve to keep the earth from washing away to some extent.

Stability. 6064. That dam has withstood floods? Yes, it has had floods over it, but I do not think there is a very straight run of water there.

By-wash. 6065. But, as a rule, the by-wash is always cut out of rock? Yes, wherever it can be done.

6066. And where that is not done, and the water is allowed to flow over the surface, there is a difficulty in keeping them clear? Yes.

Dam on Warrego. 6067. Do you know of any other dam? I know another dam on the Warrego at Pirillie; that is a dam which must be from 10 to 12 chains long.

Height and width. 6068. And what height and what width? I have only driven over it and have not examined it particularly, but there has been a lot of earth used in its formation; it is a very large dam—you could drive a wheeled vehicle over it.

Batter. 6069. Has it a good batter? Yes.

Depth. 6070. What depth of water is there above it? I do not know, but it is very deep and permanent.

Back-water. 6071. Does the dam back the water far along the creek? To the next dam about 4 or 5 miles away; there is good water all the way.

By-wash. 6072. What sort of by-wash has that dam? It has a by-wash that comes round, I should think, half a mile; and at the furthest point, I should think, it is a quarter of a mile away from the dam; it has formed a channel of its own and runs right away from the dam altogether.

6073. Is it washing away? I do not think so; it has formed a channel 40 feet wide.

Soil. 6074. What is the nature of the soil? It is a sort of clay, very similar to the soil about Bourke.

Stream. 6075. Is there any great rush of water? Yes, there is a good stream running when the water is high.

6076. From that it would appear that it is not impossible to make a dam that will stand without being built on a reef of rock? No, that dam has been erected for twelve years I believe, and it is one of the best in the Warrego.

Lake Denman. 6077. Do you know anything of the lake on the Kirribree River? Lake Denman; it is about 2 miles long and nearly round; it is about a mile and a half from Kirribie Creek.

Supply. 6078. How is that lake fed? It is fed by local rains.

6079. Not from the river? No, except in very high floods; a dam on the Kirribie Creek throws the water across a plain, and they have made a small embankment and a canal to throw the water back into the lake.

6080. That is from Kirribie Creek? Yes.

6081. Then it is fed from Kirribie Creek? Yes, in high flood.

Depth. 6082. What depth of water is there in the lake? Not more than 6 feet.

6083. How long does it last? I believe it was just dry during the last drought.

6084. Does 6 feet of water last through a three years' drought? It is not nearly full now.

6085. When it is full, about what depth of water would there be? About 12 feet I should think.

Ground. 6086. It is good holding ground I suppose? Yes.

Mud spring. 6087. Do you know anything of a mud spring at Coonbillie? Yes.

6088. Describe it, will you? There are several of them; they are on the south-east corner of the Coonbillie block; the water is at present oozing out of the mud, and the mud is banked up about 3 feet high in places; it seems to have been forced up by the water.

Appearance 6089. Has it the appearance of a cone cut off about 3 feet above the surface of the ground? Yes; there is a hole in the centre, and pure water right up to the surface.

Permanency. 6090. Are those springs permanent? I believe so.

Well. 6091. No bores have been sunk near them to ascertain if the water would flow over the surface? A well has been dug about 10 chains from the spring, at a 10 feet higher slope, out of which water was obtained,

Quality. but I believe it is only fit for stock; the water in the spring is very good.

6092. Then the water in the well is not the same as the water in the spring? No.

Fence. 6093. Is the spring fenced in? There is a brush fence round it; there are about 10,000 stock at it.

Stock watering 6094. How are they supplied with water? The water is in some places out of the spring and in holes.

6095. Does it trickle over and run into holes? Yes.

6096. Is it not run into troughs? No, there are small holes near the spring full of water. Mr. C. S. Chauncy.
6097. *Mr. Barton.*] Is that the only spring you know anything about? Yes.
6098. How do you get at the depth of the water in the Denman Lake? Only from information I have received. 23 May, 1885.
6099. And why do you suppose it would hold 6 feet more? From the appearance of the bank; I could see where the water had been up to when the lake was full. Denman Lake.
6100. *President.*] Where were you working before you were employed on the Warrego? In the county of Rous, then in the Metropolitan district; the county of Rous is on the Richmond River, on the north-east coast.
6101. Did you see any places on the Warrego or the Darling where there were reefs of rock that could be utilized in building dams? No; I have never been along the Darling, and I have never seen any on the Warrego. Reefs of rock.
6102. *Mr. Franklin.*] Have you seen any timber-constructed overshot dams? No, I have not.

Mr. J. T. Gibson called in and examined:—

6103. *President.*] What is your occupation? I am a wool-scourer near Bourke. Mr. J. T. Gibson.
6104. How long have you resided there? Four years.
6105. You have erected a wool-scouring plant and pumping machinery, have you not? Yes; the pumps supply the water for wool-scouring. 23 May, 1885.
6106. You have enclosed some ground for a fruit and vegetable garden, and you have utilized the water which you pump from the river to water it? Yes; we let the water run through the garden during the meal hours. Irrigation of garden.
6107. Is the water pumped directly from the river? Yes. Pumping.
6108. And what has been the effect of the irrigation? About three years ago we got some young fruit trees from Sydney, and now they have grown to a very large size; the peach trees are 10 or 11 feet high. Effect.
6109. Will you describe the growth of some of the trees? There are two peach trees 1 foot 7 inches round, a lemon tree 11 inches, and one orange tree about the same size as the lemon tree. There is also a small fig tree 7 feet high, which was just a sucker last year and put into the ground. We also got five seeds of Mexican grass from Baron von Mueller, three of which I put into the ground last December and now the grass is 10 or 11 feet high. Mexican grass.
6110. And what is the area covered by the grass? About 14 yards; the grass grows out from the bottom. Area of grass.
6111. What is it useful for? It is useful as fodder for horses—the horses are very fond of it. Use.
6112. You have not tried anything else with it? No.
6113. And everything else in the garden I suppose has grown proportionately? Yes.
6114. You have everything in abundance? Yes; I believe we could grow almost anything there.
6115. During the time you have had that garden what sort of seasons have you had—good ones? No, they have not been at all good lately. Seasons.
6116. And where water has not been used what has been the result? Nothing has grown—the ground is quite bare.
6117. Have the fruit trees borne well? Yes; last year a lot of peach trees were broken by the weight of the fruit. Fruit trees.
6118. And at the present time have you any oranges or lemons? Yes, I have a fair supply.
6119. *Mr. Barton.*] Have you any idea of the quantity of water it would take to water a given area? I could hardly say; I fancy about 1,000 gallons a day on an average have been used at my place. Quantity of water used.
6120. Over how much ground? About 2 acres I should think. In the summer-time we use more—in the winter, less; in the winter we only water occasionally.
6121. *President.*] Your garden is situated on the bank of the Darling, is it not? Yes. Situation.
6122. And the water is pumped up from the river? Yes, by Tangye pumps. Pumps.
6123. *Mr. Franklin.*] What means have you of distributing the water? We run it over the surface in trenches, and flood the beds. Distribution.
6124. Have you attempted to make watercourses, by raising the ground and cutting trenches in the raised banks? No. Raised trenches.
6125. Do you think you could consolidate the earth so as to make it impermeable and cut your trenches in it? I believe we could; in the Chinamen's garden they have raised trenches.
6126. You spoke of a new kind of fodder you have grown from single seeds: can you give anything like the approximate weight of the growth from these seeds? No. Fodder.
6127. Can you roughly estimate what the whole of it would weigh if you cut it down? I fancy it would be more than a man could carry.
6128. Then would you estimate it at 2 cwt.? I dare say it would be between 2 and 3 cwt. Weight.
6129. That is 1 cwt. per seed: what area of ground would that occupy? The seeds would require to be in drills 6 feet apart, and the seeds themselves 3 feet apart. Seeds.
6130. And what area of ground would these three seeds cover? About 2 square yards to each seed. Area.
6131. Then this weight of 3 cwt. of fodder only covers 6 square yards? Yes.
6132. So that upon that basis we could calculate what an acre would grow? Yes.
6133. *Mr. Barton.*] Does the plant seed with you? It is in seed now; I intend to plant another patch next year. Seed.
6134. *Mr. Franklin.*] You pump the water directly from the river? Yes. Pumping.
6135. Have you found the river too low to operate on it? No.
6136. Is the river always flowing past your place? Yes. River flowing.
6137. And is it continuous down the river past your place? Yes.
6138. It is not in waterholes? No, it has never been in waterholes since I came here; about a mile and a half below there is a ridge of rocks across the river, and the river is always running over it. Waterholes. Rocks.
6139. Do you know if it has caused any inconvenience to the people on the river for watering stock or other purposes by its being so low? I do not think so; I think there has always been sufficient water for watering stock: the only inconvenience that might have been felt has been from its getting shallow and the stock crossing and re-crossing. Water for stock.
6140. Has this low state been the cause of the loss of stock by bogging? Yes. 6141. Bogging.

Mr. J. T. Gibson. 23 May, 1885.

6141. And you think that if the river could be kept at a moderate level it would be beneficial for watering stock? I think so.

Machinery for irrigation.

6142. *Mr. Murray.*] You simply utilize your machinery for irrigation when it is not in use for wool-washing; but do you think it would pay to have machinery for the purpose of pumping up and irrigating alone? I think it would pay to irrigate the ground for green stuff for horses.

Banks.

6143. Do the banks of the river consist of good soil? Very good on the high parts.

6144. Capable of producing anything I suppose? Yes, if there is plenty of water.

6445. The banks of the river are good retaining soil; there would not be much difficulty in the way of making dams in the river at Bourke? In some places there would.

Escape of water.

6146. Why? I think the bank is porous; there are holes cut through. Before I came to Bourke I lived further down the river, on a station, about 600 miles away, and I made a dam across the creek, but the water all got away through the soil—not over the dam nor under it.

6147. *President.*] Did you ever try to ascertain whether the water percolated through the soil? I gave it a trial, but no more.

Dams in Darling.

6148. Do you consider that a dam could be made in the Darling, or in any of the branches of the Darling where there was no reef of rock? Yes: I do not say that the soil is porous at every place—I think you could find places where it would be sufficiently good for a dam.

Reefs of rocks.

6149. Do you know of any reefs of rock? Yes, there are great many below here.

6150. And if a dam were made at one of these reefs sufficiently strong to stand, would it hold the water? Yes, so long as it had a good by-wash.

By-wash.

6151. Do you think a by-wash would stand unless hewn out of rock? Yes, if you got a good long billabong.

6152. But suppose you utilized the natural channel and let the water go out above the dam, do you think that would in time of flood wash into as large a channel as the river bed? It would depend on the outlet; if it were low it would take a long time, but if it were high it would sooner cut.

Dams.

6153. But from your knowledge of the Darling for some years, you think it is practicable to put dams across the river and dam the water at certain selected spots? I think so.

Fodder.

6154. *Mr. Franklin.*] What is the nature of the fodder that you spoke about? It is something like maize or sorghum; the seeds are very small, like oats with the two sharp ends cut off.

6155. Do you know if stock generally will take it as food? Our horses eat it, and cattle also will eat it.

6156. Is it growing on the average soil of the banks of the river? Yes, on the high places.

6157. I suppose it would not grow on flooded ground? I could not say.

6158. You say it would produce at the rate of 1 cwt. to 2 square yards on the average soil of this district? I think so, if it got sufficient water.

6159. Then it would produce 120 tons of artificial food per acre? Yes; it is the best growing fodder plant I ever saw.

6160. Do you know any other people who are growing it? No; I think only a few seeds came to Bourke.

Mr. J. J. Higgins called in and examined:—

Mr. J. J. Higgins. 23 May, 1885.

6161. *President.*] You live somewhere near the Paroo River? Yes, I am employed there as a licensed surveyor.

6162. How long have you been out there? About two years and a half.

The Paroo.

6163. I want your evidence in the first instance about the Paroo River: what is the nature of the country on that river about the watercourse? In common with most rivers with a westerly course the Paroo widens as its length increases, and disappears eventually in the plain, generally forming a large shallow lake, and the water remains in that lake a longer or shorter time.

Bed.

Lake.

6164. Where does the lake form? Near Tonga, about 70 miles above Wilcannia. That locality would represent the lake formed by the Paroo flood-waters, the same formation that exists in the other rivers.

Size.

6165. What size does the lake form? It is a system; if it were full it would probably be 40 miles by about 15.

6166. That is the overflow from the Paroo? Yes.

Floods.

6167. And that country is nearly covered when the river is in flood? Exactly; it is filled when there is an unusual quantity of water.

6168. Have you any idea of the length of time the water remains there after a flood? In the deeper part of the depression the water would probably last, I think I am justified in saying, eighteen months or two years, but very much would depend on the seasons.

6169. What is the depth of the deeper part? I could not accurately say; I should think about 13 feet.

Evaporation and soakage.

6170. Do you think that the water goes away principally by evaporation or by soakage? A great deal of it must disappear by evaporation; but that subject seems to be so little understood that I could not give a definite opinion; the best authorities seem to know but little about the matter.

Formation.

6171. What is the nature of the country where the system forms—the nature of the soil? It is a lacustrine deposit overlying an impure limestone of compacted strata, or a cemented sandstone, whichever you will. It consists of disintegrated portions of quartzose rocks cemented together by a deposition from foraminifera associated with purer limestone. That is my definition of it, if I am to go into technicalities; it is the only description I can give as a technical one.

Porosity.

6172. Is the material porous? It depends altogether upon the depth and the pressure to which it has been subjected. At a great depth under great pressure it becomes solidified and will become almost marble, according to the purity of the limestone, or it will become sandstone if lime is absent. If sandstone it will be more or less porous, like all sandstones. If the proportion of lime or foraminifera shell is greater, then it becomes a compacted limestone and impervious to water; and all the conditions between the two obtain in this underground stratum; it is a cretaceous formation.

6173. Do you know of any instances in which sinking for water has been carried on in that country, either by boring or sinking wells? Yes—both.

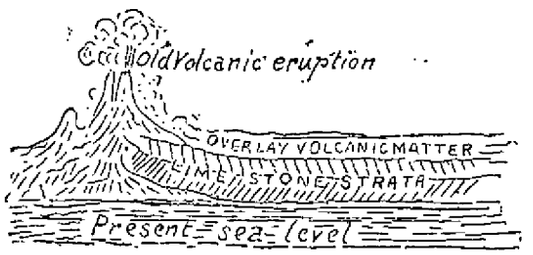
6174. Will you give the Commission any particulars you can? I have not taken any notes; I can only give my impression of the country as I saw it.

6175. Will you describe those you are acquainted with as well as you can, and define their position as nearly as possible on the map? Before I saw the country I was aware from Mr. Clarke's writings on the subject of the supposed existence of an underground drift; and, broadly speaking, from the volcanic upheaval

Structure of country.

upheaval of the main range of the Colony; the particles of disintegrated plutonic rock have been washed into water—probably a shallow sea—and carried about and distributed levelly by the ocean currents that obtained in that sea. That is apparent as you go out over the black-soil plains—the Liverpool Plains and others; you can see that they have been levelled by water, and that they consist almost solely of plutonic matter, identical with the plutonic rocks in the mountains forming their watershed. This ceases somewhere about the Bourke district, or to the eastward of it; you then get into limestone formations, where the plutonic matter is not carried quite so far. The system of plains is more to the eastward, and as you come westerly from the main range you lose that plutonic matter in coming to the limestone formation, and the limestone formation becomes visible under it. The limestone formation is carried a long way—how far I do not know. It has been part of an older system, and has been thrust up and disturbed by the volcanic agencies of the higher mountains. Now we will find it go off somewhere—where it does not matter—but

Mr. J. J. Higgins. 23 May, 1885. Limestone formation.



at all events it has been cut off and is covered over by the disintegrated particles of the volcanic range. Then we come to the country showing on the surface the older conditions; that is, the undisturbed conditions of the limestone formation simply upheaved, but not disturbed by violent contortions. You find this 15 miles to the west of the Darling, in the bottoms of little lakes and such like. That obtains right out to the Paroo; and it is into that cretaceous limestone that the wells I am speaking of have been sunk. As the places become shallow, sea plants and erosion have placed a layer of loosened matter on top of the compacted limestone which has been raised. That has been pierced about 25 miles from the Paroo River, on Paroo Plains block No. 5; the place being well known as O'Grady's Well. The well is about 400 feet deep. O'Grady's Well.

6176. Describe the strata which occur there? For about 15 feet the well goes through that more or less friable strata, the result of deposition all over the surface. I cannot speak with certainty of the next 50 feet; it is a mixture which I did not examine particularly, but after that it gets into compacted impure limestone or sandstone, whichever you will. Strata.

6177. At what distance from the surface? About 50 feet. Then after slight breaks—I cannot say whether they have ever hit on the first drift that obtained—and getting salt water that has probably been made salt by percolation through strata which had been the bottom of a shallow sea for years, and would be to a large extent composed of decomposed sea-weed—it gets into the limestone of which I spoke, and goes through it for about 50 feet, coming to fairly good water and fossil shells at a depth of about 450 feet.

6178. And it passes through the limestone at about 450 feet? About 400 feet, or, allowing the other to extend further, say 350 feet, which would represent pretty nearly, I think, the compacted strata of which I speak.

6179. *Mr. Barton.*] Does the water rise in that well at all? Yes, but the only information I have as to the height is from conversations I have had. I think there is a rise of about 250 feet. Rise.

6180. *President.*] That is an open well? Yes.

6181. Do you know whether any of the salt-bearing stratum has been kept for analysis? I have never heard of any; I do not think it is likely that we have as yet any analysis. Analysis.

6182. Where is the next well that you have any particulars of? West of the one I have spoken of there is another, but I do not think that I need take up any time in describing it—the conditions are so nearly similar to those in the last. It is on Osaca No. 1 block, towards the western boundary of Sir Samuel Wilson's run. Other well.

6183. It is similar in every respect to the one you have already described? Yes, and about the same depth, evidently piercing the same strata.

6184. Do you know any other wells or bores? North-west of O'Grady's well at Urisino—West Paroo No. 2—there are two wells. The first is a small one about 3 feet square, and has a pretty continuous supply of water at a depth of 28 feet—pure, fresh, excellent water. Wells at Urisino.

6185. Does that water rise partly to the surface? No, it maintains a uniform depth; it is the bottom of a little watershed—a purely local affair.

6186. What is the water found in? In the top stratum I speak of—in that friable stratum—but from some cause or other it is not impregnated with salt. It is not easy to explain why that is so. This well is not connected in any way with the stratum I speak of; it lies above it, in the friable 50 feet. From some cause it has been arrested and lies on a compacted bottom of its own, above the other water-drift altogether. Perhaps it may be connected with some of the little creeks which obtain between the ridges; there may be a drift of some kind or other. It does not affect anything in the shape of artesian water.

6187. Describe any other well you are acquainted with? Nearly 7 miles north-east from the former, on the same block, another well has been sunk, and at a depth of 130 feet—of course some allowance must be made for the correctness of the figures I am giving—salt water has been struck; that is in the top stratum. They went through that and pierced the sandstone stuff at a depth of about 80 feet perhaps. Through some break or other which occurs—some drift connected with the loose stuff—the salt water percolates. At from 130 to 150 feet they struck very good water, a little salt, but good enough for stock; in fact good enough to drink. Then they sank deeper, intending to strike the same drift which was struck in O'Grady's well; but after going down 450 feet, an accident happened to the drill, and the work was abandoned. Another well was put down on Urisino No. 6, 12 or 14 miles west of the one I have just been speaking of, and at a depth of about 120 or 130 feet, somewhere about this compacted drift, they struck salt water—too salt to do anything with. Then they went down I think 400 feet, the difference in the thickness there being due probably not to any difference in the depth, but to the difference of contour on the surface. They got excellent water there, and a good supply; there were 7,000 sheep watering at it when I passed last.

6188.

Mr. J. J. Higgins. 23 May, 1885.

6188. Was it artesian water? Unquestionably.

6189. About what height did it rise? To within 150 feet of the surface—perhaps less than that.

6190. And the strata passed through was similar to that in O'Grady's well? Yes, and I heard that they got fossils at the bottom.

6191. Do you know of any other wells? About a little to the east of the first plain we spoke of lies a ridge, which I believe to be the watershed between the Paroo and the Bulloo Rivers. About 30 miles from the last well I spoke of brings us to the Bulloo Lake, which is a lake similar in formation to the lake on the Paroo; it is about 60 or 70 miles long and 20 or 22 miles wide in its greatest breadth, with a maximum depth, I have heard, of from 10 to 12 feet, and an average depth, we may say, of 5 feet. It disappears into drifts and by evaporation, the same as the others.

Bulloo Lake.

6192. It is formed in the same way as the lake you have described on the Paroo? Precisely. The well I was speaking of lies to the west of this lake about 17 miles, on the Bollwarry block, about 100 miles to the east of the South Australian border. We have already spoken of the overlying of plutonic matter over the limestone on the eastern side of this flat country which we have come over, with the system of small lakes with their own watersheds. As we get further west we come on to the remains of the old islands of the shallow sea, similar to the islands now in the straits to the north of Australia. These form the Mount Brown ranges, and the action of sea-water or of waves washing on them is still visible on some of the higher altitudes. With regard to the deposition of this compacted strata which we have already pierced, it seems to me, although I have not made any critical examination, that there is some kind of dip taking place, probably by the matter from the hills being washed down. It is the bottom of the old sea beginning to get level—beginning to come up as we may say—and at a depth of 150 feet we come on to good water at Connulpie.

Well on Bollwarry.

Old islands.

Water at Connulpie.

6193. Before you get to the good water do you pass through the usual stratum with salt water? I have forgotten whether there was water in that or not.

6194. But the same stratum was passed through? Yes; I examined the material taken out of the well and found it exactly the same.

Stratum.

6195. And that well is only 150 feet deep? Yes, and it contains tolerably good water and a very fair supply; but it is salt water—much salter than you would like to drink.

Depth of well.

Quality.

6196. But it does for stock purposes? Excellently well for sheep, but not so well for horses.

6197. Are there any other wells out there? 10 miles further to the west there is a well in which the water has been struck at a depth of about 100 feet, and a very excellent supply of water has been obtained, much better than that at Connulpie. It is close to the outlying ridges of the Mount Brown system.

Other well.

6198. And shallower? Shallower by 300 or 400 feet.

Depth.

6199. And did they go through the same strata there to get water as they did more easterly? Through exactly the same formation, and I am inclined to think it is the same strata.

trata.

6200. It is a cretaceous formation? Yes.

Formation.

6201. Do you know of any other wells to the south? I know of a well, but I cannot give you any particulars about it, except that the water is very salt.

6202. The information you have given us with reference to the wells includes the borings you know of in the western part of the country? Yes, the borings would be where the wells were sunk. The wells would be sunk a certain distance, and then the bores would be put down lower.

Borings.

6203. What was the size of the bores? 8, 6, and 4 inches.

Size.

6204. Do you know of any other places where bores have been put down? No, not where there have been any different results.

6205. Do you consider that the Paroo system is the same as the Bulloo, or is there a division? There is unquestionably a division.

The Paroo and Bulloo systems.

6206. What do you suppose that division is—is it an upheaval of any kind? Yes, a higher upheaval—probably a lateral force.

6207. Your theory is that there has been at some earlier age a sea on both sides of that upheaval between the two systems? Yes, and the upheaval itself has been covered by sea; it is only an inequality in the bottom of the ocean, or caused by irregular upheaval.

Upheaval.

6208. What do you suppose becomes of the water which is lost in the Paroo and Bulloo, and which forms those lakes? It percolates away into the drift and evaporates.

Percolation and evaporation.

6209. Is it the same water that is found in the lower cretaceous formation? That I could not say; it is possible that the system of percolation continues underground, and the water which is struck 200 miles away may be the water we lose here. Through the upper stratum above the compacted impure limestone an enormous quantity of water passes by percolation.

Underground water.

6210. But did I not understand you to say that that was usually salt water? Yes, that it is water partly salted by the decomposition of vegetable matter at the bottom, and which was probably at one time seaweed, and the deposition of salt at a later period when large bodies of fresh water began to collect and afterwards evaporate. Many of the plants there have had a marine origin, and developed to their present form by climatic and other natural conditions.

Salt water.

6211. Then you consider that the water may percolate through the upper strata and be found a distance away, or go down to the lower cretaceous formation? Yes, and possibly it meets with branches of the great underneath drift at various depths and runs away; there is no other way of accounting for its disappearance.

Underground currents.

6212. Do you know anything of a large dam on the Paroo? Yes.

Dam on Paroo.

6213. At what part of the river is it situated? I know six or seven dams on the Paroo; in fact, roughly speaking, from the 29th parallel to the lake I have spoken of the river is dammed all the way.

Position.

6214. Are those dams usually built promiscuously in the bed of the river, or are they sites selected where there are reefs of rocks? From the 29th parallel on the Paroo River there is a small channel approximately in the centre of a depression; and this channel opens out and the depression itself opens out also until at last the whole thing is nearly flat, and the dams are built across this little depression in the centre of the channel.

Sites.

6215. In building the dams, are sites selected where there are reefs of rocks? Not necessarily.

6216. What I want to know is, is it usual and practicable to make a dam across the Paroo that will stand with a by-wash without the dam being made of rock as a foundation, or the by-wash being cut through rock? Unquestionably; but you must protect the by-wash by gravel or stone, or some such material; it will be a constant object of attention; nothing will keep it but constant attention if constructed in the loose soil, but still it is done, and done practicably.

Construction.

6217.

Mr. J. J. Higgins. 23 May, 1885.

6217. *Mr. Barton.*] Do you know of any depressions or lakes or anything of the kind on the Paroo where large quantities of water could be stored, either by turning the river into these places or by damming the billabongs or depressions at any particular part, and so conserving large quantities of water after floods? On Kulkine creeks, about 30 miles to the east of the Paroo, there are low lying hills with narrow openings between them in which large quantities of water might be conserved by damming. I should think that some of these ridges would average from 4 ft. up to 15 ft.; perhaps a little more, but not much I should think. Storage.

6218. Is that the only place you know of? Between the Paroo and Bulloo there are large depressions, but it would be difficult to say what depth of water we should have in them; nothing but a complete system of levelling would ascertain that.

6219. Do you know much of the Cuttaburra? That is the Kulkine which I am speaking of. The Cuttaburra is an ana-branch of the Paroo it seems to me, but I have never run it round. The Cuttaburra.

6220. Do you think that there is any place on the Cuttaburra or Kulkine where large quantities of water could be dammed back? There is one place where a very large body of water could be impounded—at an out station between Nocoleche and Wanga Mana.

6221. Have you had any experience of the mud springs out there, or the soda springs as they are called? No; I have seen them, not here but on the head of the Gwydir. Soda springs.

6222. *Mr. Franklin.*] Have you seen the Paroo River in time of flood? Not in time of high flood. Floods.

6223. I suppose you know that the discharge is sufficient to fill any number of dams—as many as are placed there now? Yes. Discharge.

6224. Has it ever occurred within your knowledge that the upper dams intercepted the discharge and prevented the flow below? Yes, it has.

6225. Do you think it possible that by means of dams a sufficient supply might be conserved not only to fill the whole of the river, as far as it is defined as a river, but also to flood that large area of lakes and swamps? Unquestionably; it has been flooded or the lake would not be there. Supply.

6226. These lakes occupy an area apparently of 2,000 or 3,000 miles on the map? You might even add something to the well defined area, viz., the large area which would be covered with shallow water on the upper side of the lake. Area.

6227. That water would disappear by soakage into the soil? It disappears, as we saw, by soakage through the tertiary that overlies the compacted limestone and possibly penetrates it. Soakage.

6228. Then having disappeared in the ground it becomes deteriorated by contact with saline matters? From the evidence which I have given with reference to the formation you will be able to form as sound an opinion on that subject as I can. Water getting salt.

6229. As a matter of fact, I think it is generally known that as long as water is retained on the surface it remains pure? There is one condition which always obtains, that is that no matter how large a body of water may be it will become salt by evaporation.

6230. Even on the surface? Yes; the lake of Asphaltites and one or two others have gone through that process.

6231. But that would only occur in salt water in the lakes? No; it is caused by constant evaporation; even perfectly fresh water will become perfectly salt if it remains standing and evaporation goes on; if the outflow is less than the inflow the lake will become salt.

6232. Then as long as the particles of water are kept in motion it will be fresh? Yes, by overflow; motion by wind will not keep them fresh.

6233. Then supposing that a better system of damming were adopted on the Paroo—on the whole length of it—by which you might conserve water and regulate it down by sluices, it would remain pure throughout the whole length, and the whole of the dams could be charged? Unquestionably; but I do not know what would be the natural chemical action of saturation after such a system of damming had been in existence for (say) a period of 100 years.

6234. Then do you think that having regulated the water through the length of the river it would be possible to grade the water on a higher level, with probably a smaller fall, and so avoid that waste to the swamps? Yes; I have often thought that some system of the kind might be carried out effectually. Distribution from Paroo.

6235. Then it would run the water through the country? Yes; for about 30 miles on each side of the river, and small areas could be made productive by irrigation.

6236. Do you think it would be a great advantage if the waste waters of the Paroo could be regulated from the terminal point of the river, and through country where the water could be graded? Yes; that is the only system which could be carried out.

6237. Then it would be of importance to find where it could be graded out? Yes.

6238. Under the present condition of things it is simply a waste of water to throw it over the swampy ground? Yes, a waste of both land and water.

6239. Is there any timber to be found on the Paroo suitable for dam-building? No; there is timber there but it is not suitable for dam-making; I think that timber for the purpose would have to be brought up the Darling somehow; the timber on the Paroo is too crooked; there is a limited supply of beefwood, but I do not know how that would stand water. Timber.

6240. Is there any stone in the ridges you have mentioned? Yes; there is plenty of limestone sufficiently large to build dams. Of course this is only a suggestion, but I may mention that 30 or 40 miles back from the Paroo there are enormous masses of felspar which when burned makes pure plaster of Paris; that would be good enough for cementing the stone facings of dams. Stone. Felspar.

6241. Do you find that in large nodules which would make the slope of a dam? Yes; there are large cliffs of it on the banks of a lake near the Queensland border—water-worn cliffs nearly 20 feet high composed of pure felspar; it is also found in other places; there are thousands, or even I may say millions of tons of material there. Cliffs.

6242. So that in designing permanent works it would be better to use masonry than local timber? I should say so decidedly.

6243. And you are of opinion that with overshot dams the water could be regulated so as not to injure the people below, and to give them a fair supply? I think it would be necessary to have overshot dams. Overshot dams.

6244. *Mr. Murray.*] Do you think that much silting would take place if you had these masonry overshot dams? Yes. Silt.

6245. Would that not be a danger? That would have to be provided for in the construction of the dams. Silting will occur in any dam.

6246. Have you seen any cement made from the gypsum found in this district? No; but there is a house built Cement.

Mr. J. J. Higgins. 23 May, 1885.

built of it at a place called the Gypsum or the Crystal Palace down near Wilcannia, on the road between Wilcannia and Hay.

6247. In your opinion, what is the most suitable system of water conservation for this part of the country, taking the friable nature of the soil into account, and the difficulty of getting any high grade of land for canals or anything of that kind? That is a very comprehensive question. I should want time to get my ideas together, but I think that by a system of locks you might effectually get water about 30 miles on each side of the stream, taking the water from the higher to the lower levels.

Water conservation. Locks.

6248. *President.*] Are you speaking of the Paroo or the Darling? Of the Paroo; whatever dams are found to be necessary, the general principle will have to be the same in all of them, and the sites would be those best suited to the configuration of the country.

Wells and tanks.

6249. *Mr. Murray.*] In a great many places I suppose there is no possibility of getting water except from wells? Or else by making deep tanks. Tanks, unless they are over 20 feet deep, are not of much use for keeping stock alive, as they are not permanent.

6250. *Mr. Franklin.*] Do you know the Darling higher up? No, I am not at all acquainted with the Darling higher up, but I know some of its branches thoroughly.

6251. Do you know what they call the billabongs along the river? No, I am unacquainted with the Darling River; the Namoi and the Paroo, Peel, Gwydir, Mooki, and that system I know well.

Banks.

6252. I suppose you have observed generally on all these rivers that there is a large deposit of silt after floods, and this having been repeated for ages has raised the banks of the rivers higher than the surrounding country? That is the case at Bourke, as I can see, but further up it is unquestionably the case; in fact, on all alluvial rivers that I have examined throughout the Colony that condition of things invariably occurs—the deposited alluvium raises the banks.

Salt water.

6253. *Mr. M'Mordie.*] I think you gave it as your opinion that in salt water the salt is supplied by marine deposits? Possibly.

6254. Possibly or generally? Where water is found in the friable soil at the surface an enormous quantity of salt must be taken up and held in solution as it percolates through it.

6255. But I think you said that the salt is generally obtained in marine deposits? I think that it would be partly the result of vegetable marine deposit. Large salt deposits are not the result of marine deposits by any means; they are the result of the chemical action which I spoke of in cases of large bodies of fresh water under certain conditions.

6256. I thought you meant to say that where salt water was found it was obtained from marine deposits? No; I think that in percolating through formations formed by the deposition of marine deposits a large quantity of salt would be absorbed from the soil and held in solution in the water, but I do not wish it to be understood that the actual salt formations have anything to do with the marine organic composition; it is a chemical action, and a chemical action which will occur in all bodies of water.

6257. The salt water generally found is made salt by these deposits? Yes, I think so; from that and from the decomposition after deposition. That is where the salt comes from.

6258. I thought you intimated that it came from marine vegetation? Yes, so it does, but only as a subsidiary course from strata formed by the decomposition of marine vegetation, and forming the tertiary at the bottom of shallow seas.

6259. What I wish to understand is this: it is generally believed that where the formation is found containing salt, that that formation is a fresh-water deposit? I think it is.

6260. *President.*] But I thought I understood you to say that the upper strata you speak of in that country was in many instances the bed of a shallow sea? Yes, it was.

6261. Containing saline properties? Yes.

6262. And the water percolating through that extracted the salt? Yes; but the salt is the result of a natural action which takes place in all large bodies of evaporating water.

6263. Then you say that in some cases salt water derives its saline properties from fresh-water deposits that have become saline, and in other cases from the deposits of the inland sea? When the upheaval reached the surface of the sea a large quantity of water must have been impounded, then evaporated, and quantities of salt dried and deposited there. This has become mixed in the tertiary which obtains at the top now, but, as I stated before, this amount is but small compared with that deposited from bodies of fresh water at a subsequent period.

6264. *Mr. Barton.*] In the same way that that process is carried on now in Lake Torrens, where at one time you can see brackish water and at another time a foot or 18 inches of salt? Yes; as soon as evaporation takes place there is an end of the salt water—any percolation must be that of fresh water.

6265. *President.*] It is by percolation through salt deposits that the water becomes salt? Yes; the rain-water of the present time becomes salted in that manner.

Mr. Edward John Bloxham called in and examined:—

Mr. E. J. Bloxham. 23 May, 1885.

6266. *President.*] You are a very old resident here? Yes; I have been living in the district nearly the whole of the last twenty-five years.

6267. In what capacity—have you been managing stations, or what? I was managing partner of the Bogan River Company.

6268. How many years ago was that? It was at the end of 1859 or the beginning of 1860 that I first took the management.

Flood.

6269. At that time I suppose there was no water except that found in the river beds—no artificial water? Just previous to my arrival there had been a considerable flood.

6270. But there was no artificial water? None; all natural water.

Droughts.

6271. This country has been and is subject to a series of droughts, is it not? Yes; if the whole time were taken together, probably nearly half of it might be called a season of droughts, perhaps about an eighth suffering from flood, and three-eighths fair to good seasons.

Seasons.

6272. From your experience, do these droughty seasons come in a series continuously, and then moister seasons continuously? Yes, I think it may be said they do to a certain extent; there is no regularity at all about them.

6273. You have not been able to ascertain any regularity one way or the other? No.

6274. There may come a number of seasons wet, and then a wet and a dry season? What I think we have generally had has been two or three very good seasons, and they have gradually got worse and worse until they became very bad.

6275.

Mr. E. J. Bloxham.
23 May, 1885.

6275. And then improved again? Then improved; it goes round that way.
6276. During the time you have been here you have seen very high floods in the river? Yes; I have seen the highest floods any white people have seen. The flood of 1864 was the highest of all. In 1863 there was a flood perhaps 2 or 3 feet lower.
Floods.
6277. Were these floods higher than the flood of 1870? Considerably higher; the flood of 1863 must have been higher, but the flood of 1864 was certainly 3 feet higher.
6278. The floods then covered a very large extent of country? Yes.
Width.
6279. About what width do you suppose? In some places as much as 20 miles wide—perhaps more in some places; there would be islands here and there, but the flood extended to the edge of the red land wherever it was to be found.
Red land.
6280. Then the red land as a rule is not flooded land? No; the flood-water does not get on to the mulga there; the red land appears to me to have been the coast of an original lake.
6281. Is the red land the land you call mulga land? Yes.
Flow.
6282. Does the water flow rapidly in flood-time? It is a most extraordinary thing in my observation with regard to large floods that the water on the plains will be almost dead, but if you cross one of the billabongs which occur so frequently on both sides of the river, you find the current in the billabongs stronger than in the river itself; how to account for it I do not know, but I have found it so in my experience; it required a great deal of navigation to get across these billabongs.
Last seasons.
6283. Have the seasons of late been as dry as formerly? The last two or three seasons have been rather drier than former seasons, except those from '64 to '68. The last nine or ten months have been somewhat wetter than average seasons; we have seldom been short of 10 inches of rain, excepting between '64 and '68, and I look upon that as a fair average season; I pay no attention to the 16 or 17 inch reports we see.
Observations.
6284. Why, do you not consider them correct? I believe in my own observation.
6285. But do you keep any rain-gauge? I have often taken the rain-gauge.
Water conservation.
6286. During the last few years there has been a great deal of water conserved on various stations along the river? Yes, a great deal; during the last twenty years the works have been going on; in the first few years I was in this part of the country I did some very heavy works.
Storage and climate.
6287. Do you think that the storing of artificial water affects the climate here at all? I cannot say that it has done so to any appreciable extent. I noticed in the time of the big flood that there was quite a different appearance; every day we had heavy clouds—it was one continuous period of cloudy weather; but it was not the rain here that made the flood; in fact, little if any fell previous to the country being covered with the '64 flood, which was at its highest on the 1st April; the pasturage was magnificent, the result of the '63 flood; but the '64 flood, being 3 or 4 feet higher, covered and so killed all the perennial grasses, and these had no chance to recover till the end of the succeeding four years of drought; in fact, since that flood the perennial feed has hardly recovered to this day.
The '64 flood.
Perennial grasses.
Evaporation.
6288. I suppose you have no reliable information as to the evaporation that takes place? Yes, I have observed it very closely.
6289. With what result? That it is far greater than is ordinarily supposed; I have expressed my idea on that subject often. I think that during the six months from (say) the 1st September to the end of March the water will evaporate considerably more than an average of 1 inch a day; there are many days on which it will go over 2 inches; I think an ordinary tank having 10 feet of water in it on the 1st of October will be dry before the 1st of March, with no rainfall in the interim, even though no stock water at it.
6290. But I suppose you have no idea of the evaporation from the earth's surface after rain? No, I have had no opportunity of ascertaining with anything like precision; the water disappears very quickly indeed. Of course it depends a great deal on the time of the year when the rain falls; just now I should think there is scarcely any evaporation, or next to none.
The Darling.
6291. You know the country well, I suppose, in the vicinity of the Darling? Yes, I used to know every inch of it in this district.
Billabongs.
6292. There are a great number of billabongs and watercourses that go out from the river? Yes, ana-branches that go out and come in again; lower down the river there are some that go 10 or 12 miles back and come in again, but there are none at this end that go so far out.
Dams.
6293. Have you known any dams to be placed in the Darling? No, but there are plenty of natural dams.
Natural ridges.
6294. By natural dams you mean the ridges of rock? Yes, there are plenty of them; I think I could count half a dozen between here and 50 miles down.
Dams.
6295. You have known dams to be placed across the ana-branches? Yes, many years ago I put one myself across an ana-branch; that is the only one I remember; it was not a large one; I think there is a large dam in the same spot now, put there by Sir Samuel Wilson; that is what they call the Tallywalka on the Dunlop Run; that goes out further from the river than any one I know of; I think it must go 5 or 6 miles back.
6296. Is that dam formed simply of earth? I believe so; I have not seen it, and I cannot speak positively; the one I put there was an earth dam; it was carried away more than once.
6297. Had you a by-wash? No, there was no by-wash; it was built in a very shallow part of the Tallywalka, and was not a success; most of the water ran back again as the river fell.
6298. Do you think it is possible to erect dams across the Darling at the reefs of rock? I think it is quite possible; I think the only way to make the Darling available for traffic is to build up these natural impediments with the stone on the spot.
Earth dam.
6299. Do you think a simple earth dam would resist the waters of the floods? Certainly not—it would be washed away the first flood; I would use the stone that lies there.
Navigation.
6300. Then you would require locks? No; proper boats adapted to the river and to suit all our wants at the present time; in fact, to navigate the river in sections; speed is of secondary importance to certainty.
6301. How far would one of these dams back the water? My opinion is that four of these obstructions, raised about 20 feet high, would make the river perfectly navigable from here to Walgett at all times.
Acre's Rocks.
6302. Would you not apply the same principle below Bourke? To a certain distance perhaps; but I do not think that kind of work should be done for the benefit of Adelaide and Melbourne. One of the greatest obstructions is Acre's Rocks, half-way between here and Wilcannia; from this place to Walgett the river, by means of the weirs I have suggested, would contribute very largely to the traffic from the Bourke terminus.

Mr. E. J. Bloxham. 23 May, 1885.

6303. Do you consider navigation of primary importance? Yes, in order to make the river a feeder to the railway.

Navigation. 6304. But supposing weirs were made across the river with locks, and the river filled with water, do you consider that that should be done in the first instance for the purposes of navigation? I do not think it would have any other beneficial effect than for navigation.

Irrigation. 6305. Do you think that if the river were kept full the flood-water would be utilized for irrigation or stock purposes? With regard to irrigation, I may be allowed to say, though it is an unscientific opinion, that I do not think there is sufficient rainfall on the western slopes to irrigate the country 5 miles back from the river.

6306. I think you said just now that the river is 20 miles broad in heavy floods? Yes; I have seen 3 feet over the bank of the river here.

6307. Supposing a large portion of that water were prevented from running to waste, would it not irrigate a great deal of country when stored in natural basins at various places? Yes, no doubt it would, but a flood occurs so very rarely; but when they do occur, the natural depositories being all full, medium floods would be as devastating as the highest floods we have known, and would come much more suddenly upon us.

Height of floods. 6308. But you have the river-bed full, I suppose, every year or every two years? Yes, there is more or less of flood in the river every year, but nothing like a banker or even half a banker can be relied upon.

Irrigation. 6309. Supposing that most of the water that comes down in flood-time were stored, would not that suffice to irrigate a large extent of country? I do not believe that it would irrigate more than 4 or 5 miles back from the river—not for a thoroughly adequate system of irrigation. I believe, however, that those 5 miles would carry more stock than the whole district does now.

6310. But supposing a system were adopted by which the bed of the river was kept full of water with a system of weirs, do you not think that, as far as it would go, the water would be utilized? It could be utilized; but, however much you get in the river, I do not think you could keep sufficient to thoroughly irrigate more than 4 or 5 miles back.

Utilization of water. 6311. But do you think the people along the river would take advantage of the supply and utilize it? I have no doubt they would as far as it would go, if supplied to them at small cost. At the same time, I think

Cost of dams. the construction of anything like masonry dams or locks in the river would be a greater expense than the country is worth in fee simple; the country is not good enough to stand such an enormous outlay.

6312. What do you estimate would be the cost of putting weirs across? I could not form an opinion. We have plenty of water for all practical purposes, putting wholesale irrigation out of the question. All the water that would come naturally backwards we can do as well without, because it would not go far enough to do continuously any practical good.

Banks. 6313. Are the banks of the river higher than the land further away? The banks are always higher in every watercourse in these flat countries.

6314. Do you know what the cause is? No, it is a puzzle to me. I know the country is gradually getting

Flood deposits. higher in the course of ages. Every flood that covers the valley of the Darling gives one inch or more of deposit, but the banks of the river being the last places covered often miss getting the deposit that is left elsewhere, and thus their being the highest parts is the more unaccountable.

Distribution. 6315. Supposing water were conserved and diverted into broad channels or canals made to carry streams in different directions, do you think that would improve the country in the filling of tanks? As far as the Darling is concerned, I do not think you could carry water more than 20 miles back, because sometimes the country rises nearer the river but seldom further away than 20 miles. If the red ground is closer to the river on one side it is always some distance away on the other.

6316. Do you know that in the flood of 1870 the waters of the Darling and Lachlan very nearly met? The country must be much lower than I imagine if it did.

The Willandra. 6317. Do you know the Willandra Billabong? Yes; but I cannot imagine that the Darling waters reached there. The narrowest place between the junction of the waters must have been at Terrawinnia Lake, where the dry land must have been fully 70 miles in width. There is a backbone between the Lachlan and the Darling, as there always is between any two watercourses in these districts.

Lakes. 6318. There is a great number of lakes and watercourses that could be filled from the Darling? Yes, but for no practical good; they are too near the river, with a few exceptions on the lower river, such as Terrawinnia Lake.

6319. But if water were taken 5 or 6 miles from the Darling, would not that be of practical good? Yes, to some extent, but stock can reach the river from that distance.

6320. Supposing it is not permanent? It would do good to make it permanent, but to no very valuable extent; stock can go to the river.

Growing capacity of country. 6321. Supposing people could obtain water for irrigation, do you think this country is capable of growing any great quantity of hay? It is capable of growing any mortal thing, with sufficient irrigation—no other country can equal it; but on the other hand, there is no country that requires so much water for irrigation purposes, in consequence of the dryness of the climate.

Hay-growing. 6322. But supposing the station-holders along the river adopted the practice of growing hay and storing it, could that be practically carried out? It would be carried out to a greater extent if the holdings were smaller, but I question if the larger holders could ever carry it into operation successfully.

6323. But if the holdings were smaller? Then people, I think, would be more likely to try to provide for a smaller number of stock.

6324. But supposing that a man with a small holding had means at his disposal to irrigate and grow as much as ten small holders would do, would he not do it? There is nothing to prevent him from doing it now; there is always plenty of water in the river for small irrigation works.

6325. But supposing a number of squatters along the river all adopted a system of irrigation, would there be water enough? Not to water any great extent of country—not further than 5 miles on each side; but still if they would do it, why do they not do it now?—There is nothing to prevent Sir Samuel Wilson from attempting to cultivate; he has plenty of water to irrigate a considerable extent of ground, and plenty of money to do it with.

Toorale and Dunlop Stations. 6326. Of which station are you speaking? Toorale and Dunlop.

6327. Has he suffered from dry seasons? He has suffered in the same proportion as other people have; he has a very large extent of back country and 70 or 80 miles of Darling frontage, besides the Warrego and other watercourses.

Mr. E. J. Bloxham. 23 May, 1885.

6328. Then, from the nature of your replies, you do not consider that much good would be done by weiring the Darling, keeping the bed of the river full, and filling up the ana-branches and all natural depressions where water could be stored? As far as stock go it would not be of much good, but it would be beneficial in making the river a feeder to the railway by means of navigation.

Railway versus Navigation.

6329. But do you think it necessary to depend entirely on the navigation of the river? You will want something to find traffic for the railway.

6330. But supposing the Government were to make a railway along the river? That would do perhaps better than navigation. But I think the mode of damming the river which I propose would be cheaper than a railway along the river; a railway along the river would go through flood country.

6331. But supposing it was carried on high country along the river—it need not be very close to the river, but sufficiently close to carry all the produce? Oh yes; I think the railway would be preferable, but question much if the traffic within its influence would pay working cost, without interest on construction.

Cost of railway and weirs.

6332. And what do you think would be the cost of a railway as a feeder to the line—say 100 miles in each direction, up and down? If it were constructed on the same principle as the railway to this place, the cost would be vast. I have never yet been able to learn what it does cost, but have heard over £4,000 per mile.

6333. But supposing a line were made at a cost of £3,000 a mile, that would be £600,000, and if you were to put there six or seven weirs across the river do you not think they would cost as much? No; I think the weirs I speak of could be constructed for £20,000 apiece.

6334. That would be for the purpose of navigation only? That is all.

Sections.

6335. And then you would have sections in the river and make the steamers unload at every weir? Yes; it is all the country is worth; you cannot afford to erect heavy masonry works.

Value of irrigation.

6336. But suppose the country were irrigated 5 miles on each side of the river, would it not be worth the outlay then? It would make the country more valuable, but the cost of it would be heavy to the people who made use of the water. I know they could grow anything and everything, but the question is whether the people up country, having no costly irrigation to pay for, could not supply us at a cheaper rate.

Value of land.

6337. What would land be worth per acre with plenty of water—what would it be worth on the extra production? No doubt you could keep five times more stock on it than you can keep now.

6338. Then the land would be increased by five times its present value? I think so, but perhaps it might cost ten times its present value to bring about that increased value.

6339. And would it be worth £1 an acre to pay for water, supposing you could obtain plenty of water to irrigate it properly? I do not think so.

6340. Not if its value were increased five times? No, I do not think so; it is not only the cost of obtaining a sufficiency of water, but the cost of applying in sufficient quantity to meet the extra requirements of such an arid climate.

6341. What is its value per acre now? Speaking from sorrowful experience, I may say that every man relying upon this country here alone, without anything else to back him up, is ruined once every seven years.

6342. Then it is worth less than nothing? It is so; as hitherto held it is ruination.

Loss of stock.

6343. There has been a great quantity of stock lost in this district during the last drought? Yes. I would not call it drought; it has been somewhat drier than the ordinary seasons, but it was not such a drought as we had from 1864 to 1868.

6344. What proportion of stock do you suppose has been lost? Some people talk about one-half, but I do not think it has been nearly so much; I should say one-third.

Causes.

6345. For want of grass or want of water? Want of grass—a great many more have been lost from want of grass than from want of water; there may be more water saved from rainfall in all seasons than is sufficient for all the stock the ordinary rainfall will provide feed for.

Underground water.

6346. Have you had any experience of the underground system of water in this district, more especially between this and the Queensland border? Only in the neighbourhood of the river; and I have had some experience at Bourke. I have found that you have to sink 40 feet to get water here, just to about the level of the river at the present time, but if the river were full there would be no more water in the wells.

Salt water.

6347. That is near the river? Yes. If you get any distance beyond the river you come upon salt water at depths varying from 15 to 60 feet.

Mud springs.

6348. Do you know anything of the mud springs? Yes, I have found many of them.

6349. Do you think they contain permanent water? They contain permanent thin mortar.

6350. Can you take out enough to get pure water? No, you cannot get a drink, except of this liquid mortar, which fills in as fast as you bale it out.

6351. We had evidence this morning of 10,000 sheep being watered at one spring? I have never seen it; nothing can drink stuff of the consistency of the overflow from the mud springs, as they are called; but I am under the impression that it is the same water as is found in the reed springs alongside them, but where it comes out in the liquid mud state it is water forced through a bed of pipeclay.

Reed springs.

6352. And where these mud springs are found do you find clean springs alongside them? Yes, within a few yards. At the mud springs you will see a white mound with nothing whatever growing upon it. The reed springs, in their original state when first found, were like a sugar-loaf of green river reeds, exactly the same reed as the Murray River reed, although I do not suppose that between here and the Murray you will find a reed of the same description.

Source of underground water.

6353. I suppose you have no idea of any system of underground water? I conclude that the water comes from the coast range—the range from east to west in Queensland, and from north to south in this Colony.

6354. Or from the northern Queensland range? Yes.

6355. But I suppose the theory is that the water soaks underground and reappears in certain places? Yes, through strata more pervious than others. If it was possible to trace the course of the underground water there would be a plentiful supply of water to get along with grass, though probably not a wide stream. It is very difficult to trace I fancy. It is beautiful water in the clear springs, but there is really no water in the others; it is mud—though if pipes were sunk I dare say you would get water below the pipeclay. I may mention a curious thing in connection with one of these mud springs—one of the largest I ever saw, and close to one of the best springs in this neighbourhood—at Yantabulla. I used to be in the habit of going across there before the country was much inhabited. Once, when passing the spring, I saw an immense mound, which had disappeared when I came back, having apparently sunk down to where it came from; had I ridden over it, my horse and self would probably have disappeared.

Yantabulla spring.

Mr. E. J. Bloxham. 23 May, 1885. Goonery Spring.

6356. Were you the original discoverer of the Goonery springs? I believe I was.

6357. How many years ago was that? That would be shortly after I came here, probably in 1860 or 1861. The place was then a mound of reeds. These reeds were in a cone which seemed to have been formed of decomposed vegetation. You had to look down from the top of the cone, and then you saw the water some distance down.

6358. Did you consider that that was an extinct mud spring? No, entirely different in appearance, and the liquid produce—one nothing grows upon, the other the most luxuriant river reeds. There were mud springs close alongside it. But although it was a grand spring to look at, it was a failure as far as springs go. I could see that it did not make a great deal of water, and I had a 200-gallon cask which I emptied and filled from the spring, after taking some of the decomposed vegetation out of the bottom. But I could only fill the cask in twenty-four hours; it would not supply more than 200 gallons in twenty-four hours, and yet it was a splendid-looking spring. The best spring for supplying water is one near the Warrego, I believe

Leila Spring.

now called the Leila Spring. I took it up as a mineral selection in those days, before we ever heard of minerals in this country. I think it will be found to be the earliest selection made in this district after the passing of the Land Act of 1861 as a mineral purchase.

6359. Then it is alienated? It was, but it has been allowed to lapse since. I think the Government took half of it away originally, and the rest of the purchase has been allowed to lapse.

6360. And is it a reserve now? Yes, though I am inclined to think there is a 40-acre purchase of some sort belonging to the station on it still—an improvement purchase probably. But that was a very fine spring. During a very dry season we kept three or four flocks of sheep constantly watered there. We had an embankment 4 feet high all round it. That used to fill with water, and then we had a pipe to lead it over the top.

6361. Was the water good? Yes, very good.

Trusts.

6362. Do you think that, in dealing with the water systems of the various rivers, it should be left to private enterprise as it is now, or that there should be legislation to deal with the whole water system by the establishment of Trusts? I cannot imagine any great good from dealing with the rivers except for navigation purposes.

6363. But I am speaking of any river system—take for instance the Paroo, the Warrego, or any of these rivers in connection with which you might form a Trust for the purpose of conserving water, and the same would apply to portions of the Darling? I think the matter would be better in the hands of Trusts than in those of the Government.

6364. To be administered locally by practical men? Certainly. Our experience here is that we can manage matters better locally than the Government can manage them at a distance.

6365. And though you do not think that any great improvement would take place, still if any improvement would take place the matter should be in the hands of local Trusts? I think so.

Boring.

6366. Have you had any experience in boring? None whatever. From what I hear, it has been a failure here so far.

6367. But you have had no experience of a private nature? No. On reconsideration I would like to amend something I said in a former part of my evidence. I dare say it will be recorded that I thought the turning of

Filling of billabong.

the waters into the billabongs would be of little or no service. I would now say I think it would be of some service, though it would be of no great importance. It would be of some advantage to get water 3 or 4 miles permanently out from the river. Generally there is water in those places, but it would be better to make it certain.

6368. And you still think it would be of little use trying to divert a stream of water through the dry country? It would be of use if it could be done, but my experience of this country is that 10 miles back it rises into high ground and you cannot——

6369. But if it could be done it would be of great use? Of course it would.

Irrigation.

6370. We have had some evidence in reference to irrigation near the river—you said that water enough might be obtained to irrigate 5 miles on each side of the river? There might be enough, but I hardly think there would be.

6371. Supposing that could be done, do you not think that it would ensure the safety of as much stock as there is on the stations at present? These 5 miles would keep more stock than the whole of the district keeps now, and would ensure a vast deal better wool; because some time in every year in this country the sheep are in such a state—I will not say exactly of semi-starvation, but in a falling-off condition—that the wool always suffers in consequence. For a month or two or more in every year in this district that is the case; they are never thriving the whole year round. If you had 5 miles of irrigation on each side of the river you would always have green grass, but the sheep on the irrigated land would not be so healthy.

Irrigation and sheep.

6372. Why do you think the sheep would not be so healthy? You would have foot-rot, and probably catarrh and fluke.

6373. Did you ever know of fluke in the salt-bush country? No, I do not think I have, unless brought there by sheep from fluky country, but the salt-bush would be no antidote to fluke in constantly flooded ground.

6374. Did you ever know sheep get fluke from feeding in cane-grass swamps? No; there is nothing there to eat. The cane-grass swamps have nothing in them but tufts of cane-grass far apart, acres being quite bare and shining when dry like the bottom of a saucer. The cane-grass is almost like diminutive sugar-cane.

Evaporation.

6375. *Mr. Barton.*] In giving your opinion as to the evaporation in this district, I see you put it down at about 16 feet for the summer months—have you ever employed any test to enable you to arrive at that? I do not think I said that.

6376. You said an inch a day on an average for six months? I am within the mark if I did say so. There are plenty of days when it goes 2 inches a day.

6377. Have you ever taken any means of testing the evaporation? No, perhaps not. I have seen a dam on the Toorale Station which I suppose kept back 10 or 12 feet of water, and which was protected by trees, and I have known it to dry within six months after it was full.

6378. Have you ever had any experience of a tank sunk for stock—say a 20,000-yard tank—and left for the season without any stock being watered at it? No.

6379. There might be absorption as well as evaporation, and you may be confusing one with the other? There will not be so much soakage out of the natural bed as through the broken surface of a dam or tank.

However,

Mr. E. J. Bloxham.

28 May, 1885.

However, I have had no such experience as a six months' test of a tank without stock watering at it, but I have seen water going so fast that I know it must have been at the rate I have mentioned.

6380. Do you know of any large depressions, large billabongs, or dry creeks, in close proximity to the Barwon or any of these rivers, where by a reasonable outlay large quantities of water could be conserved? I would instance the Dry Bogan, which I look upon as a billabong of the Darling. It would not be very hard to fill that and to stop the water. Dry Bogan.

6381. And do you not know of any large natural reservoirs as it were? The same remark would apply to all the billabongs, but they are not a sufficient distance back to do any great good. Reservoirs.

6382. Not to conserve water that might be taken elsewhere? No, I do not know of any natural depression except billabongs of any depth. The nearest one I can think of is one we used to call the Utiara Swamp, on the Toorale Run. It was one of those cane-grass swamps, in fact, and it was filled with water in the time of the big flood. Of course as the flood fell away the water fell out of it. From what I recollect of it, I think a bank of 3 or 4 feet for ½ a mile would have kept the lake full of water 5 or 6 feet deep. There are plenty of these cane-grass swamps. Utiara Swamp.

6383. You stated that you had had experience of the great floods in this district—did you mention that you had experience of any flood before 1863? At the time I delivered sheep from Bogan Station to Furlong, some of the flocks were standing in water. That was in the 1863 flood; and when I first came here there must have been a flood just preceding, because the country was in a most luxuriant state, as we only see it after a large flood. Floods.

6384. From your experience in the country before and after stocking, and stocking heavily, is it your opinion that, as the country gets stocked up, these various rivers and tributaries of the Darling will be subject to much higher floods than before; or do you think otherwise? I do not think that will affect it much, because the local rain never affects the river to any extent—the water all falls away from it. Effect of stocking

6385. But I think you know that when you first came up here, and after the flood of 1864, we have had 3 or 4 inches of rain that put no water into the local rivers; I think you must have witnessed that in January, 1868, for instance? We had no rain from 1864 to 1868. The rain of January, '68, was unusually heavy, and probably had a slight effect on the river, but no merely local rain would make the river rise more than 2 or 3 feet, and it would be at its former level within ten days. Local rains.

6386. But this was only a rain in January? The country is more trodden now, and more rain enters the river, but only to a very limited extent. I think it might possibly affect the river a little more than it did in those days. The ground was not nearly so well trodden down then as it has been since. I was thinking of this with reference to what future floods might do, if we had great floods again such as we had in 1864.

6387. Whether the same quantity of rain would produce a much higher flood? I do not think it would. Every river in the country must be in flood as it was then to produce what we had then. I do not think that the fact of the ground being trodden hard would affect the size of the flood—not when it comes to be a flood of that kind.

6388. As to that proposition of yours to lock the rivers simply for the benefit of transit, or rather of damming the river and navigating it in sections—do you think if it was possible to put a railway on the high ground on either bank of the river up and down for 100 miles, that that would be a more economical and satisfactory way to bring the traffic than by damming the river? I do think it would be much better. I do not know whether the cost would not be greater, but it would be safer and more regular, and do away with the necessity of insurances and many other drawbacks incident to navigation. Railway and navigation.

6389. Now, in the matter of irrigation, I heard you say that you thought that by irrigating the country it would carry five head of stock to every one it carries now: what is your opinion as to the average number of sheep the country will carry at the present time? Any man who attempts to make it carry more than one sheep for every 8 acres will be a heavy loser, and many have lost heavily at that. 8 acres for one sheep I regard as necessary to safety, and during plenty of years they would be in a state of semi-starvation if there were 80 acres to every sheep. Irrigation. Sheep-carrying capacity of country.

6390. And is it your opinion that it would take an acre and a quarter to carry a sheep if the country were irrigated? I really believe that less would do, certainly less if under English perennial grasses.

6391. Do you know that land irrigated by squatters as an experiment has been known to carry thirty sheep to the acre? Not within my experience—not from natural grasses I should think.

6392. No, not from natural grasses, but from English grasses? The country would carry five times the present quantity of stock if it were irrigated.

6393. What do you estimate to be the actual profit on every sheep kept in paddocks in the present circumstances? Much depends on the position. Profit on sheep.

6394. Well, say in the immediate vicinity of Bourke—between here and Brewarrina—suppose I had a run of 10,000 or 20,000 sheep upon it, what should be the yearly profits on these sheep, under the best and most economical management, making allowance for every expense: what I want to know is the present profit as compared with the profit under irrigation? That is a question which requires consideration. My own opinion is that there is no profit arising to people from keeping sheep in this district. I would not like to name a sum. People have made money by buying empty runs, and then stocking and selling them.

6395. There was a lake mentioned to-day called Lake Denman? I often used to ride across that country without knowing that there was a lake there, but as a place for saving water it has become very valuable since then. I was never fortunate enough to see any water there. I have not been there since the country has been inhabited, but I may never have gone across the right spot. Speaking of the billabongs, I think a great deal might be done by the removal of a bank which invariably forms near where they come out of the main stream; that is the case at the junction of the Dry Bogan. If a cutting were made the Dry Bogan would often have a much finer supply of water than it has; and upon a large scale there is the Cattawarra, which might be made to run every time the Warrego runs. Invariably there is a bank where a small stream comes out of a large one. Lake Denman. Cuttings.

6396. *Mr. Franklin.*] You are well acquainted with these billabongs, are you not? Yes.

6397. Have any of them been formed during your time? No.

6398. Is it your opinion that these billabongs were at one time part of the river bed? No, I think not—not of the original course of the river. I think every flood tends to deepen the billabongs, as a very strong current sets through them; as a rule they make a short cut from one bend of the river to another, and the water has only half the distance to travel to what follows the bed of the river. Formation of billabongs.

Mr. E. J. Bloxham. 23 May, 1885.

Erosion.

6399. Do you believe that if you were to make a cutting through a sharp bend of the river as straight as you could carry it the banks would erode and give you a straight run, leaving the old bed as a billabong? By breaking the ground you might make the cutting become the main bed of the river.

6400. As a matter of fact, the material in this district to the depth of the river is likely to erode by the pressure of water during flood-time? The clayey bed of the river does not alter much, though the banks do considerably.

6401. But is it possible that the banks will erode and make a more direct channel? I do not know any instance where it has done so, though I have known points to give way and fill up at opposite points. At a point on the Darling River, in the middle of Bourke, at least 20 feet have gone from one bank of the river, and the bank on the opposite side has made up somewhat in consequence.

Stationary water from overflows.

6402. Have you observed, in every case that you are acquainted with, that the water which overflows from the billabong will remain stationary on the ground over a large area after the flood has subsided in the river? I do not think so—I think they drain away as a rule with the river.

6403. You do not know of any country falling back from the river? I do not know of any part of the country where the water remains to any useful extent in this part of the Darling after a flood; it always finds its way to the river again.

The Darling a drain.

6404. Can you give us any idea of how the billabongs were formed in the first instance? I cannot tell you. For my part I look upon the Darling as a drain kept open by the western rainfall, after the original salt lake (which now forms the valley of the Darling) silted up to such an extent that, after some such rainfalls as caused the '64 flood, the salt lake broke over the bounds that held it, cutting an outlet at a place now known as the Clifts (on the Tolarno Run, I think), joining the waters of the Murray salt lake; the united waters then cutting a road through by the Mallee Clifts into what is now Lake Alexandrina.

6405. You do not know any case where a billabong has overflowed its banks, and there being no creek in the vicinity the water has lain there a considerable time? No, it falls with the flood.

Raised banks.

6406. What is your general impression as to the height of the banks of the river—are they generally higher than the surrounding country? Yes; and often the banks of the billabongs are higher than the country at the back.

Sheep per acre.

6407. In estimating that you could not place more than one sheep to 8 acres, did you confine yourself to this part of the country? There are many parts of the country where they could not put sheep at all, having as yet no water supply. I was speaking of the Bourke district, or, I may say, of the Darling, because they can do no better all down the Darling than we can do here.

6408. From your answer it might be inferred that you spoke of the whole country? No; I spoke of the country from Brewarrina downwards.

6409. Would you modify your statement with reference to the country nearer to the rainfall? Yes; the further east you go the capacity of the country becomes greater. Perhaps, if there is any difference as you go westward it becomes less.

The Paroo.

6410. Do you know the Paroo River? Yes, from about 100 miles above the border.

6411. Have you ever seen that river in flood? Yes; but it was only in 1864 that it was known to get through to the Darling.

6412. What has prevented its running through? There is no channel—the river spreads out.

6413. The latter part of it has no defined course? An observant person could trace it by the timber; it runs into lots of billabongs and flat country. A large area of it runs into swamps, forming in fact a series of small, shallow lakes.

Diversion from the Paroo.

6414. Supposing you stopped the river where it has well-formed banks, would it be possible to lead the surplus water by a canal through the low dry country? I have no doubt you might turn it off to the east or west, but you would get no depth.

6415. But does it not occur to you that there must be an enormous quantity of water wasted, and that it would be worth while to inquire whether that could be stopped and stored? I do not know of any natural places where it could be stored. You might turn it into the swamp country, but it would last no time.

6416 But do you not think it worth while to ascertain whether some storage place could be discovered? I do not know the country well enough to answer that question.

6417. But do you think the matter of sufficient importance to warrant further inquiry? Certainly.

6418. We have evidence that there are many dams on that creek which discharge water over large areas of country, and that soakage takes place before the river reaches the swamps? Does your evidence show that there are any natural reservoirs?

6419. No, it shows that there are large areas of swamps, and that if we diverted the water from the terminal points of the well-formed channel it might be stored and conserved in its transit through dry country in tanks? My opinion is that there is no part of the country lower than the bed of the Paroo itself.

Effect of diversion on the Darling.

6420. But suppose we could save the water and convey it into the bed of the Darling, would not that raise the water in the bends and be beneficial? Every little drop of water does assist the Darling, but neither the Warrego nor Paroo water alone would have any material effect on that river.

6421. But would not a constant supply maintain the current and keep the water very much better for stock than it has hitherto proved; the Paroo watershed would not keep up a constant supply to the Darling? There has always been a current in the Darling, and abundance of good water for stock.

6422. Then the surface water of the Paroo would not benefit the Darling itself? No; it is only in times of excessive flood that it reaches the Darling at all. Those swamps you spoke of are a considerable distance from the Darling.

6423. I want to lose sight of that altogether, and to bring the water that makes them into the river below? It would aid the river a little, but not very much, and would not be constant. The Paroo is a very paltry stream—you can cross it in many places without knowing it.

Lowest part.

6424. Can you give me the name of the lowest part of the river where it begins to run into the swamps? The country at the bottom of the defined line of the Paroo consists of hard, red mulga ridges. A survey would be necessary to prove the depth of cutting necessary to convey the water from the defined bed of the Paroo into the Darling; probably the greatest depth would not be more than 8 or 10 feet, but I think it would be of little service beyond occasionally giving water to the blocks through which the cut passed.

Value of land.

6425. *Mr. M'Mordie.*] You stated that the land in the Bourke district taken over a period of seven years is not worth anything? My opinion is that it is ruin for a man who depends on sheep only, and the prevailing absurd ideas of grazing capacity.

6426.

Mr. E. J. Bloxham. 23 May, 1885.

6426. What is it of any value for, if not for sheep? For blackfellows and kangaroos, or perhaps for one sheep in place of the three it is now expected to keep.

6427. Might I ask you what price quarter-acre blocks of land are now selling for in the town? They have been fetching enormous prices; they have brought as high as £2,500 for half an acre,—prices that have contributed much to the present local commercial depression.

Chinaman's garden.

6428. *President.*] Do you know a purchase made by a Chinaman on the bank of the river? It is not on the bank of the river. I suppose you are referring to Tim Yung's garden. He is said to have paid £3,000 for 6 acres of land, but it was an already formed garden, and a large sum of money had been laid out on it. However, he will never pay it.

6429. What is he using that land for now? For a garden.

6430. He is carrying out a system of irrigation? Yes; he pumps the water out of wells, and the consequence is that his garden is not nearly so good as the gardens of those who get their water from the river itself.

Irrigation. Quality of water.

6431. Then you conclude that the water in the river is better than the water in the wells? Far better for irrigation purposes.

6432. Do you know of any case where irrigation has been resorted to and has failed? The well water will kill some things.

6433. I am speaking now particularly of the Darling water? I think it is splendid for irrigation purposes—it contains an immense amount of fertilizing matter; but I am not aware that irrigation to any extent has been tried; I know of nothing more extensive than the Chinaman's garden.

Productive land.

6434. And if there was sufficient water to irrigate to any great extent, irrigation would make the land more productive? Yes, I cannot imagine any more productive land than this, with complete irrigation; but it would require an exceptionally large quantity of water.

Mr. Edward MacFarlane, District Surveyor, Bourke, called in and examined:—

Mr. E. MacFarlane. 23 May, 1885.

6435. *President.*] How long have you been district surveyor here? Since the commencement of this year, and acting district surveyor since 1881.

6436. What part of the Colony were you living in before that? I was working from Dubbo between Mudgee and the north-western part of this district.

6437. You have taken considerable trouble to make yourself acquainted with the underground water system of the north-western and eastern part of this Colony, have you not? I paid attention to what I saw as I went along. I have travelled over almost the whole of this part of the country.

Mud springs.

6438. You are well acquainted with the country commonly known as the mud springs? Fairly well; I know the locality of most of the springs.

Situation.

6439. Can you indicate any system or supposed system of those springs? I think so. The line of springs in New South Wales begins about 10 miles from the Queensland border, and about 30 miles from the Culgoa River, in a north-westerly direction. There are three or more springs there, all close together, and within an area of 180 acres.

Plans.

6440. Have you plans of those springs? Yes. The names of the springs are Moulton; south-westerly from those springs are Sandy, Tooloomo, and Shearer's Springs (Shearer's or Gerrara).

Direction.

6441. In what direction are they? They all follow a south-westerly course.

Distance.

6442. And how far distant are they? From Moulton Springs to Shearer's Springs the distance is about 18 miles.

6443. Is the water similar in all those springs? I could not tell you anything about the nature of the water.

Country.

6444. Is the nature of the country in which they appear the same? Yes.

Source.

6445. Where is the next spring? The next is Collis's Spring, about 18 miles further on, also in a south-westerly direction. The next spring is Nellie Spring, about 12 miles from the last.

6446. The water in the springs you have named you suppose to come from the same source? Yes; apparently it comes from a north-easterly and goes in a south-westerly direction.

6447. Have you any information as to the width of the country in which the springs are situated? None whatever.

Bores.

6448. Have any bores been put down in the springs? None that I know of.

Line of springs.

6449. Does the water flow over the surface? A little at all of the springs. The springs are all small and unimportant, but they indicate a line of spring country.

Country.

6450. Is the country level? Fairly level—undulating country.

Kullyna Springs.

6451. Now take the next series of springs? The next would be the Kullyna Springs situated about 50 miles almost north of Bourke, and 2½ or 3 miles east of the Warrego River. The next spring is Leila Spring, to the west or a little to the north of west, and about ¼ of a mile from the Warrego.

Goonery Springs.

6452. Are there any further springs continuing that series? The next in continuation of that series is the Goonery Spring.

Distance.

6453. How far is that distant? About 50 miles distant, in a south-westerly direction.

Malya Springs.

6454. Are there any further on? The next would be the Malya Spring, about 50 miles south-west of Goonery. Next to that is the Wee Watta Spring, about 8 miles south-west of Malya.

Spring near the Paroo.

6455. Do you know of any springs further south? I know of no springs south-west of this where the water comes over the surface. Warroo Spring near the Paroo River, and near the Queensland border is the most north-western spring of another series.

Jacombe Spring.

6456. Where is the next of that series? The next I know of is the Jacombe Spring, but I understand that there are some springs intervening on the same line.

Other springs.

6457. What is the next one? The Yantabulla Spring; then the Boongunyara Spring, distant from the Jacombe about 10 or 11 miles. 6 or 7 miles further on we have the Youngarigina, still going towards the south-east, and again the Coonbillie Spring, 6 or 7 miles more east than south-east of the last spring.

6458. Is that the last of the series? Yes.

Direction

6459. The series you have just been describing runs from north-west to south-east, in an opposite direction to that of the first and second series? Yes.

6460.

Mr. E. MacFarlane. 23 May, 1885.

6460. Then I understand that, in your opinion, there is a line of underground artesian water running from north-east to south-west in two parallel lines? Yes.

6461. Can you say how far distant they are from each other? The first two series are about 16 or 18 miles apart, the second continuing further to the south-west than the first; a third series, coming from the north-west to the south-east, seems to cut the second at right angles.

Strata. 6462. Have you any information as to the depth of the strata through which those springs come? None whatever.

Boring. 6463. Has there been any boring at any of the springs? Bores have been put in at Goonery and Wee Watta, but I do not know to what depth.

Supply. 6464. Did they strike the water? Yes, in each case a full supply has been obtained from the bores.

System of springs. 6465. Then your belief is that there is an underground system of springs running much in the same way as the surface water runs? Yes.

6466. But you have no information as to the width of the run of water? None at all.

6467. And you do not know in what layer of clay or whatever it may be that the water is confined before it rises to the surface? No, I have never had time to make a close observation of the places. I simply became aware of their existence generally, with a view to securing as much reservation as possible at them.

6468. There are other springs throughout that country with which you are not acquainted? Most probably.

Reservation. 6469. Have the Government made reservations at most of the springs? At all the important ones there is a sufficient reservation.

Thully Spring. 6470. Is there anything further you wish to state with reference to those springs? There is a spring called Thully Spring lying to the south-east of the springs of which I have already spoken. It is north of the Darling, and west of the Culgoa like the rest.

6471. Do you not connect that spring with any of the systems you have described? I have never seen anything to lead me to connect it with them.

Distance. 6472. How far distant is it from any of the other springs? It is nearer to Nellie Spring than to any other, and about 21 or 22 miles from that. Another spring is the Cuddie Spring, 15 miles south of the Artesian spring. Darling. It contains first-class artesian water, which rises to a height of 6 or 7 feet above the surface, and is about 9 miles east of Mara Creek, in the county of Clyde.

6473. Is that a mud spring? It was originally a mud spring. It is in a hollow 100 yards across or more, and in the hollow a well has been sunk to a depth of 28 feet. Great difficulty was experienced in sinking the well, owing to the way the sides fell in, but timber was used to keep up the sides. The water now trickles over the top of the timber, which is several feet above the surface of the ground. In bad seasons the stock have been taken to that part of the run, and the water has been led into troughs, at which the stock were watered.

6474. Is that spring on private land or on a reserve? It is on a reserve.

Quality. 6475. Is the water good? It is beautiful soft water.

6476. What size is the well? I should think 4 or 5 feet square, or a little more; it is the usual size of a square well.

Supply. 6477. Is there much of a supply? There has been an inexhaustible supply.

The Ginget. 6478. Do you know of any other springs south of the Darling? I do not know of any in which the water rises over the surface. The Ginget is a watercourse extending from the Macquarie River in the vicinity of the Macquarie Marshes to Mara Creek, which it joins about 5 miles distant from the junction of Mara Creek with the Darling River.

Source of underground current. 6479. That underground current you speak of from the Macquarie Marshes—do you suppose it comes from the water lost from the Macquarie? I do not see any reason for thinking that it does not; we have no evidence that it does except that the water is there.

Wells. 6480. Have any wells been sunk? Yes, continually along the course.

Result. 6481. With what result? With the result of obtaining water at a depth of 20 feet.

Rise. 6482. Does the water rise at all? That I cannot say; I do not think it does.

Quality. 6483. Is it good water? It is beautiful water. In sinking the well, drift sand was reached at some distance from the surface, but a box was put into the drift and any amount of good water was obtained.

The Ginget. The utility of putting dams into the Ginget seems to be that the dams retain the water for a long time over the sponge, so that it becomes thoroughly saturated. I look upon the part of the Ginget from which the water is drawn as a great sandy sponge.

6484. You know of no other place south of the Darling where we could look for artesian water? I do not.

Quality of spring water. 6485. Is there any difference in the water of the springs in the various lines you have described in your evidence to-day? So far as I know, the water in all of them is the same, and it has the same effect on the human system.

6486. Then what reason have you for thinking that they form various lines or series? That is only an opinion I have formed from considering the matter, and I have heard nothing that contradicts it.

Series of springs. 6487. You cannot trace one series of springs by one kind of water and another series by another kind of water? No, not so far.

Wells. 6488. Do you know of any other wells of importance north of the Darling? I do not know of any other wells to the east of the Paroo. There are wells to the west of the Paroo, but I have not particulars of them.

Basin of Darling. 6489. You are well acquainted with the basin of the Darling, are you not? Pretty well.

Weirs. 6490. Do you think it is possible by means of dams to fill the bed of the Darling in time of flood? Yes, I think it is possible by means of weirs.

Position. 6491. I suppose the most suitable places to put those weirs would be where the bars of rock are? Yes.

Ana-branches. Warraweena. 6492. Do you know of any ana-branches that would be filled by that means? Yes, in addition to those that have been mentioned to-day, the Warraweena Billabong is an important feature. There is a peculiar and noteworthy feature in connection with that billabong. At Warraweena head station there is a great sheet of water in ordinary seasons, and water has been conserved by means of dams. The peculiar feature to which I want to call attention is, that what is a large sheet of water at the upper end joins the Darling by a puny narrow channel. This seems to me to get rid of the idea that this billabong was ever an old bed of the river.

Storage. 6493. That billabong offers natural facilities for storing water to a large extent? Very great facilities.

6494.

Mr. E. Macfarlane. 23 May, 1885.

6494. What is its length? It is at least 20 miles long.
6495. And throughout its whole length the bed is of sufficient size to store large quantities of water? Throughout two-thirds of its length.
6496. And dams could be easily made for that purpose? Yes.
6497. And if there was a dam near the off-take, would that fill the ana-branch in ordinary floods? Certainly; it fills in ordinary floods now. The thing is to retain the water.
6498. What is the average width of the billabong? About 3 chains. Width.
6499. Is that at the top? Yes.
6500. What would the width be about half-way up the bank? About a chain and a half. The bottom is fairly round. Bottom.
6501. What is the average depth? I dare say it is as much as 20 feet. Depth.
6502. Are there any other billabongs you could point out as being suitable for storing large quantities of water along the Darling? I do not know of any other very big billabong. In a great flood the water breaks out above Moculta Station on the Dry Bogan, and then goes down away by the back of Bourke, and joins the Darling 6 or 7 miles below Bourke. Dry Bogan.
6503. How far does it keep out from the river? At the widest part not more than 4 miles. The railway goes over that. The Railway Department will not make an opening in the railway more than 10 chains wide, so that when the water comes down I believe it will be directed into the openings, and after a few floods we ought to have a big billabong from the scour through the railway bridge. Railway bridge. Scour.
6504. Have you any information as to the water that breaks out of the Dry Bogan at the model huts? Only that it breaks out and goes through the country 10 or 15 miles out from the Darling, and joins the water that has just been described as breaking out of the Dry Bogan. Model huts.
6505. You cannot specify any particular billabong to which you can direct the attention of the Commission particularly? Only those two—the Dry Bogan and the Warraweena Billabong.
6506. Do you think that if the bed of the Darling were filled with water, there are places where the water could be diverted into those billabongs and permanent water conserved at all times? I think so. Diversions from Darling.
6507. Without injury to the banks of the river? Yes; provided the weirs were not made too high. Banks.
6508. What would you call too high? If you came within 10 feet of the top of the bank that would be too high. Height of weirs.
6509. What is the height of the bank above the river? About 40 feet as a rule. I do not think it would be safe to go within 20 feet of the top of the bank. Bank.
6510. Why do you think it would be unsafe? Because not only is the earth very friable, but when the water gets 20 feet up it comes down with great velocity, and the scour would be tremendous. Scour.
6511. But supposing the river were filled in flood-time, would the scour be greater when it broke out into the billabong than if it kept the river channel? No; because when it reaches a certain height it usually flows into the billabongs.
6512. Have you ever thought much of the possibility of diverting the river water by means of canals into the interior of the country in times of flood, or when the water is dammed to a certain height? I think it is quite possible to a limited distance. Canals.
6513. And do you think an off-take could be made from the river and directed so that it would not scour to any great extent? Yes, by selecting favourable sites. Off-take.
6514. Have you any idea where the underground water is likely to be found to the north of the Darling—I mean artesian water? None; except in connection with what I believe to be waters connecting the various lines of springs. Underground water.
6515. Is there anything else you can suggest to the Commission which I have omitted to ask? I have here a tracing which shows the general features and the rise and fall of the country in the vicinity of one of the most important of the springs—the Kullyna; and it also shows the course the water takes in trickling from the spring as well as the reservation surrounding the spring, and the mode of reservation adopted in such cases, the area being 640 acres. I have also another tracing showing the Leila Spring and the reservation around it. Country about Kullyna.
6516. All the plans you have there show the same characteristics and the reservations of other springs? Yes.
6517. And you will supply tracings of them to be appended to your evidence? Yes. (*Appendices* X 1, X 2, *and* X 3.

MONDAY, 25 *MAY*, 1885.

At Goonery.

Present:—

MR. GIPPS, C.E., | MR. LYNE, M.P.,
MR. MURRAY, M.P.

W. J. LYNE, ESQ., M.P., PRESIDENT, IN THE CHAIR.

Mr. Henry William Ford was examined:—

Mr. H. W. Ford. 25 May, 1885.

6518. *President.*] You are foreman of water-augers? I was, on this line.
6519. Who is now? Mr. Wright.
6520. What position do you hold? I am foreman of water-augers still, but I have not got any augers.
6521. Has Mr. Wright superseded you? No; he relieved me of the augers. My work is independent of him, and my communications are direct with Mr. Henderson.
6522. Did you put this drill down at Goonery? Yes. Drill at Goonery.
6523. What depth? 200 feet 8 inches. Depth.
6524. At what depth did you strike water? Salt water at 20 feet. Salt water.
6525. Did you pipe that out? Yes; the salt water was carried on to 63 feet. At that depth we struck a bed of clay perfectly dry. At 80 feet we came into rotten sandstone and then struck artesian water. Clay bed, artesian water.
6526. How much deeper did you go? We bored to 201 feet.
6527. What through? Sandstone and shale with clay seams. Strata.
6528. Where did you get the greatest supply of water? We got a little all the way down. The first at 80 feet; the second at 100 feet; the largest at 122 feet 6 inches. Supply.

Mr. H. W. Ford. 23 May, 1885.

6529. Then what? At 192 feet we came into a big gravel bed of granite pebbles.
6530. Did you get any water in that? Yes.
6531. When you struck the water, did it rise to the surface at once? At once.
Rise. 6532. From the first level? From 80 feet. I screwed on pipes and proved it to go 20 feet high, and it was running at that height as freely as at the surface.
Formation. 6533. This is a cretaceous formation? Yes; from 63 feet.
6534. At the bottom you got into granite? We drilled 8 feet into it. It was considered to be the bed rock, and there we stopped.
Discharge. 6535. What quantity did the well discharge at first? When first struck it carried 600 gallons, and kept at that for a month.
6536. What was the cause of the reduction? It was like breaking into a reservoir, in which the gases forced the water up until it got vent.
6537. At the end of the month it was reduced to what? It slackened to 400 gallons.
6538. How long did it keep at that? Twelve months.
6539. What is the flow now? 270 gallons.
Reduction. 6540. What is the cause of the reduction? Partly from leakage in the pipe, and partly from sediment accumulating in the bore-hole.
6541. What requires to be done to make it secure? A new pipe to be put in on the top, and rods and augers to clean out the well.
Bore-pipe. 6542. What depth is the bore-pipe? 112 feet.
6543. And the rest is in its natural state? Yes.
6544. Why was it not piped all the way down? Because it was considered the hole would stand. If it had been piped to the bottom some of the water would have to come up outside the pipe.
6545. But a pipe would have prevented the bore from choking? Yes; and the pipe could be perforated at the different levels of the water to allow it to flow in.
Cost of cleaning 6546. What would be the cost of cleaning it out? About £20.
Cause of rise. 6547. Having had a long experience here, what is your idea as to the cause of the water forcing itself over the surface? It goes under the surface at a higher level than here—probably in Queensland—and there is an underground channel of water all through this country, and when tapped it will rise pretty well to the level at which it went into the ground, allowance being made for friction.
Cause of boring. 6548. What caused you to put down the bore here? Mud springs.
6549. What caused them to show? The granite coming so near the surface causing the water to be forced through the weak points in the clay.
Execution. 6550. When did you commence this bore? In September, 1883.
6551. How long did it take you to perfect it as we see it now? A little over two months, not counting the drilling into the granite, where I made only an inch a day.
Supply. 6552. It has been running ever since? Yes.
Auger. 6553. What auger did you use? The Tiffin down to 112 feet; Wright and Edwards' afterwards.
6554. Why did you not use the Tiffin all the way? It would not work as well as the Wright and Edwards'.
6555. Do you know any auger superior to those? I do not.
Diamond drill. 6556. Why did you not use the diamond drill? I never worked one. In rock they are superior to anything, but in this class of drifts I think the Wright and Edwards' superior to anything.
Second bore. 6557. When you finished the bore at Goonery, where did you go? 6 miles further on.
6558. When did you start the bore there? 4 February, 1884.
Depth. 6559. To what depth did you sink? 545 feet 6 inches.
Rocks. 6560. What rock did you go through? From 150 feet, sandstones, clays, and shales.
6561. The same formation as this? Yes, cretaceous clays and shales, with now and then bands of hard silicious rock.
Depth to water. 6562. At what depth did you get water? At 23 feet very salt water, and at every few feet to 110 feet similar water; brackish water at 350 feet, which rose over the surface. At 428 feet we struck fresh water, which also rose over the surface. A little more fresh water was got at 464 feet. There was no further water to the present depth.
Formation. 6563. What are you in still? Cretaceous shales and sandstones.
Bottom. 6564. You never went to the bottom? No.
6565. Why? I was ordered to stop.
6566. For what reason? That I was already too deep for the machine or the power of its gear.
6567. When did you finish? At the latter end of last March.
6568. That was fourteen months? Yes.
Delay. 6569. What was the cause of the delay? Mainly arising from the difficulty of getting horse-feed, from our having to make tanks for water, and to clear the road.
Tanks. 6570. Where did you put down tanks? At the bore, to catch water when it should rain.
6571. Would it not have been better to have carted water from here? We did.
6572. Would it not have been better to do that without sinking tanks? There was not enough horse-flesh.
6573. Everything was provided by Government? Yes.
6574. Did anything else prevent you from getting on? Nothing, barring the delay in getting things up from Sydney.
Breakages. 6575. Were you stopped by breakages? Several times. We had to send for duplicates of breakages to the Department of Mines, and for tools in place of those worn out.
6576. Were you not supplied with duplicates? Not of some things.
Duration of work. 6577. Suppose you undertook a contract to put down a well, and could use your own discretion as to having things just as you wanted, duplicates or triplicates, how long do you think it would take? About five or six months.
6578. Why? I would have had duplicates of everything that was likely to break.
Work per day. 6579. How much did you put down a day, working on sandstone? 4, 5, and 6 feet.
6580. How much on the clays? 37 feet, 22, 23, 10, 16.
6581. Why would it take you five months to do it? You do not know what delays you may get in clearing out water.

6582.

Mr. H. W. Ford.
25 May, 1885.

6582. How do you clear the water out? Bale it out with a valve bucket. That was one thing that delayed us at the 546 feet 5 inches bore.
6583. If you had appliances to pump the water quickly would that take long? No.
6584. Do you know that there are persons communicating from America, who guarantee to put down 200 feet a week? I do not; but it is quite possible to do so if you work two or three shifts. I have put 103 feet down on this well in four days with one shift; that was working from the surface downwards.
6585. Suppose you had as many shifts as you want, and all the appliances necessary, how long would it take you to put down this well at 57 miles? We should average 20 feet a day.
6586. About a month in round numbers? Yes; I speak of this country I know.
6587. What quantity of water does it take to work these augers? Very little indeed; the slops from the camp work them.
6588. Then it is possible to cart the water? Yes; that is where they have the advantage over the diamond drill, which cannot be worked without water. They work better if they have water, and artesian water helps greatly in clearing the drillings. Water.
6589. What quantity of water would it take to work the diamond drill? I cannot say. I used the Tiffin first, because I could tube back the drifts and swelling clays, and salt water.
6590. Why was the 57-mile site selected? Because it was supposed to be pretty good, and a fair distance considering the carriage. Site.
6591. Are there any springs on the surface? No appearance on the surface, only cane-grass flats and clay-pans. Springs
6592. Have you any idea of the distance east and west that carries running water? I have not; I think all this country until you get upon the silurian formation towards Mount Brown carries water. Running water.
6593. Have you any idea of the direction in which this water is flowing? I think from north-east to south-west, by the course of the mud springs. Direction.
6594. Why? Because north-east from Goonery there are mud springs at 10 miles—one dry one; further north-east are active ones to near Queensland borders; about 40 miles south-west there are also mud springs known as Wee Wattah and Mulyeo, on Kallara station. Mud springs.
6595. Are they dry? No. There are artesian wells at both, put down by Mr. Brown, Mr. Officer's Manager.
6596. Have you any particulars of it? No; but the particulars are in one of the publications of the Mines Department—Mr. Brown's report on the Albert Gold-field.
6597. What quantity of water is there flowing from the 57-mile bore? 106 gallons an hour. Supply.
6598. Has it ever been greater? Yes; it was 135 gallons.
6599. How long did that flow? I could not say exactly; it has not been gauged for a long time.
6600. What is the reason for the decrease? I do not exactly know, unless it is that the pipes or cracks in the rock have been obstructed by sediment where the water flows in. Decrease.
6601. If the pipes were perforated and driven down to the bottom, would that keep out the sediment? In the 57-mile bore the pipe is only 157 feet down. Pipes.
6602. What is the nature of the bore between that and the water? Cretaceous clays and sandstones, and hard silicious bands. Formation.
6603. You did not commence with a large enough tube? We commenced with a 5-inch tube. We could not put down smaller tubes until we had finished the bore, as the boring tube is 4½ inches in diameter. Tube.
6604. Why? Mr. Henderson told me to leave the bore so that the diamond drill could continue it, and not to shut off artesian water.
6605. You think it would be a good plan to use perforated pipes at the inflow levels of the bore? It would assist greatly in keeping the well open. Perforated pipes.
6606. Do you know anything of the bore which is being sunk further out? No, except that it is over 100 feet. 75-mile bore.
6607. Who selected the spot? I did.
6608. How far is it from the 57-mile bore? 18 miles. It is at 75 miles, on the road from Bourke to Wanaaring.
6609. Are there any surface indications of springs there? No. Surface indications.
6610. Has water been struck? Salt water, at 11 feet. Salt water.
6611. Have you been there since they started? No.
6612. Is there a tank at 75 miles? A small one. Tank.
6613. Was there any necessity for it? Yes; there is no other water.
6614. How long would a 400-gallon tank last the men at work? About a week; not that sometimes. Efficiency.
6615. Are there any other bores out on that road? No; there is a site for one further on, at 95 miles, on the other side (W.) of Kulkine Creek.
6616. If there is underground water throughout that country, would not one place for a bore be as good as another? Yes; the sites are selected to meet the requirements of traffic upon the road. Selection of sites.
6617. You have partly sunk a bore between Goonery and Bourke? Yes; 198 feet 4 inches. Bore.
6618. What did you go through? 20 feet of rock from the surface down; under that, sandstone and clay. Strata.
6619. How far? Down to 193 feet; then I got sandstone conglomerate. Depth.
6620. Did you get any water? Fearfully salt and bitter water from 11 to 147 feet. Supply.
6621. You are making a tank there now to enable you to go deeper? Yes. Tank.
6622. If you had the augers or drills that you might require, could you not go on with that now? Yes; we are preparing a tank now.
6623. How far have you to go from there to get water? About 4 miles. Distance to water.
6624. Could you not work it from that? I did while there was water and grass.
6625. It could be worked from that tank altogether? I think so.
6626. If you strike good water in the bore will the tank be of service? Yes.
6627. How far is the tank from the bore? 20 yards from where the bore is down now 198 feet. If the diamond drill is brought out, the water in the tank will be very useful to work it. Distance to bore.
6628. Is it the intention of the Government to erect a tank at Goonery? Yes. Tank.
6629. What sort of tank? Iron.
6630. To contain how much? I hear 20,000 gallons. Capacity.
6631. Will that be expensive? I do not know. The plates are there. Cost.
6632. What is the object of it? To hold a supply for watering stock. 6633. Object.

Mr. H. W. Ford. 25 May, 1885.

6633. Is not the tank now here sufficient to supply travelling stock? Yes, any stock that is likely to travel.
6634. Then there is no necessity for any other tank? No.
6635. *Mr. Murray.*] This bore could be turned into a shaft? Yes.
Supply. 6636. And give a very large supply? Not any larger supply than from the pipe.
Pipe. 6637. Your pipe is 4 inches? Yes.
6638. When you first tapped the water the pipe carried more than now? Yes; it would carry a great deal more if there were pressure on it.
Pressure. 6639. Would not the pressure that forces it through a 4-inch pipe force it through a much larger conduit? Yes, but not in larger quantity; a shaft would give a larger receptacle to bale from.
Shafts. 6640. *President.*] Has any shaft been sunk in this district? Yes, not far away from here.
6641. Would not a shaft in a place such as this be less likely to get out of order than a pipe such as you have now? No; there would be greater space for the sand to come in between the slabs.
6642. If properly slabbed and puddled, would there be any danger of the sand coming through? The shaft to which I refer has been puddled, and has been in use for some years, but still the sand comes through.
Capacity of dam. 6643. Do you know the capacity of the dam erected on the station? It is 1,060 yards.
6644. Does it hold water still? Yes.
Depth. 6645. What depth is it? 3 feet 9 inches.
Adequacy. 6646. Would not a dam here answer the purposes required as well as an iron tank? Every bit; it has answered all purposes for fifteen or sixteen months.
Capacity. 6647. What is the general capacity of the small tanks you sink beside the bores? 150 to 200 yards.
6648. These may be utilized afterwards for other purposes? Yes; but their immediate use is to enable the boring to be done.
Stock watering. 6649. If the bores were completed, there would be a necessity for larger tanks to water stock? Yes.
Stock route. 6650. Do you know of any other place than this road to Wanaaring where it would be suitable to put down a shaft for travelling stock? This is the only stock route that I know of in this district.
Cheap bores. 6651. Could you suggest any means for putting down the bores that would be cheaper than the present system? A cheap plan would be to have various sized tubes, and one machine to work them.
Machine. 6652. Which machine would be the best for the purpose? Wright and Edwards'.
Silt. 6653. *Mr. Gipps.*] We see that the water is perfectly clear as it flows from the pipe, that there is no deposit of silt in the basin, and yet we know that there is a pressure of 86 lb. per square inch, which ought to be quite sufficient, if there was any silt at all, to force it up: do you say that there is silt accumulating from below? I imagine that it gets down below the main supply, which rises from 122 feet.
Quality. 6654. Is the water good enough from this Goonery bore for stock to drink? When once stock take to it, they leave all other water to get it.
6655. As to the water at the 57-mile bore? It is only fit for stock.
6656. Will vegetation grow near it? Cane-grass only.
6657. Does it encourage vegetation? No.
6658. Does it give any deposit? Yes, salt.
Rainfall and supply. 6659. Does the rainfall affect the supply of water from the bore? Before rain there is usually a bigger flow, which I take to arise from the pressure of the atmosphere.
Spring. 6660. From that you would infer the water comes from a spring? Yes; the mud springs seem to show more water before rain.
Soil. 6661. Do you consider this permeable soil? Yes.
6662. Therefore an iron tank would save more of the water than would be saved if the storage was in the soil? The station tank was calculated to fill in eighteen days; it actually took twenty-one, so that the soil is almost impermeable.
Service pipes. 6663. *President.*] How high is the service-pipe at the Goonery bore? 10 feet.
6664. Have you tested the bore by higher pipes? Yes, to 21 feet, and it would flow at a higher level.
6665. As to the 57-mile bore? It flows at 3 feet, and will rise as high as 6 feet over surface, and still higher.
Source. 6666. Do you consider that it comes from the same source? No.
Surface levels. 6667. What is the difference in the height of the surface level of the two wells? 25 feet.
6668. Would not that account for the difference in the height of flow over the surface? No.
Artesian water. 6669. Could artesian water be obtained in any of the country here? In most of it.
Underground channels. 6670. Does the water flow in underground channels, or is it spread under a large extent of country? I think the main water flows in channels, but I think there is water all through the cretaceous beds.
Fossils. 6671. Did you ever find any fossils in any of these wells? Yes.
6672. In Goonery? Yes.
6673. You sent them down to the Mines Department? Yes; I also found them at the 57-mile bore.
Shaft. 6674. You have stated that there was an open shaft in this district? Yes, within half a mile of this bore.
Object. 6675. What was the object in sinking the bore here? To procure water for travelling stock—not to test if water could be obtained.
Dam. 6676. Have you known the dam at the crossing of the Warrego for any length of time? Over two years.
Depth. 6677. What depth of water have you seen in that dam? Where the stables are the depth is 10 feet; in other parts it is shallower, and in others again a little deeper.
Supply. 6678. How long have you known that water to lie without receiving an additional supply? Eighteen months.
Stock watered. 6679. During that time have stock been watering at it? Yes, immense quantities, both of travelling and station stock.
Exhaustion of supply. 6680. Do you think that the decrease in the supply at Goonery and in the 57-mile bore arises from the exhaustion of the supply? No, unless a little from drought at the heads of supply.
Small bores. 6681. If there is such an extensive underground storage as you suppose, would small bores such as you have put down have any effect in reducing it? I do not think so.
Dam. 6682. How long have you known the Goonery station dam? I saw it made, in February, 1884.
6683. Have you ever known it to become dry? Never.
6684. Is there much stock watered at it? Yes.
6685. How deep is it? 3 feet 9 inches. It is supplied with water from the bore.

MONDAY,

MONDAY, 25 *MAY*, 1885.

At Bourke.

Present:—

MR. BARTON, M.P., | MR. FRANKLIN, C.E.,
MR. M'MORDIE, M.I.C.E.

F. A. FRANKLIN, ESQ., C.E., IN THE CHAIR.

Mr. Frederick William Mackay called in and examined :—

Mr. F. W. Mackay. 25 May, 1885.

6686. *Chairman.*] You are at present a resident in Bourke: how long have you been here? Twelve or thirteen years.

6687. I suppose you are acquainted with the district generally for a considerable radius outside the town? No, I have travelled very little out of the town.

Floods.

6688. During the time you have been resident in Bourke have you observed any very high floods? Yes.

6689. Do you remember the dates of the highest floods? I came here about 1870, and there were very high floods about that time; in 1873 especially, as far as I remember.

6690. You have reason to remember that time particularly? Yes; at that time preparations were being made for banking the houses here—men were employed in raising small embankments.

6691. Do you remember if any permanent mark was made at that time of the highest portion of the flood on the banks? I am not aware.

6692. You do not remember any fixed feature which might be referred to as the flood-level of that date? No; I know that the water came down the street nearly as far as the old Commercial Bank of that time, and the town was surrounded by water. I had occasion to go past the Hospital on the road to Cobar, and I went for 2 or 3 miles through water 2 or 3 feet deep.

Irrigation.

6693. You, I believe, have assisted the growth of your own grounds by irrigation? Yes.

Well.

6694. Do you obtain the water from a well? Yes.

6695. How is that well constructed? It is of slabs.

Depth.

6696. At what depth do you find the water? At a depth of 45 feet.

Strata.

6697. What are the strata in which you find the water? Sand-drift.

Rise.

6698. On touching the water I suppose you find it immediately rises through the sand-drift? Yes.

6699. Did you never attempt to reduce the water so as to get to a lower depth? No; we found 5 feet of water ample.

Size.

6700. And what are the internal dimensions of the well? 5 feet by 5.

6701. That is 15 cubic feet to the foot? Yes.

6702. Something like 100 gallons to the foot? Yes.

Wind-mill.

6703. What means do you employ for raising the water? A windmill—the Althouse.

Power.

6704. What is the power of the mill? It is a 10-foot mill.

Pump.

6705. What pump do you use? It is a Douglas pump; it pumps from 300 to 400 gallons per hour with a fair wind.

6706. Do you find that the water keeps to its level of 5 feet? Yes.

Supply.

6707. So that you are pumping on about 500 gallons of water? Yes.

6708. How long can you keep your well working without exhausting it? I believe it will work two hours without being exhausted, and if it is allowed to rest half an hour, or even less, it fills again.

6709. So that your well is again charged by percolation through the sand? Yes.

6710. Have you heard any complaints that by excessive pumping you reduce the level of the water in the other wells in your vicinity? Yes.

6711. So that you have been led to believe that all these wells will be charged again after a certain time? Yes.

6712. Do you think then that by an increased depth in the well you would be able to hold a supply which would keep your pump going continuously throughout the day, and replenish it continually at night? Yes.

6713. And as many wells as might be sunk in the surrounding neighbourhood? Yes, at a sufficient depth.

Distribution.

6714. How do you distribute the water you so raise? The water is stored in an iron tank, and then by means of a hose conveyed to different parts of the garden.

Storage.

6715. The object of storing in the iron tank, I suppose, is to keep the water at the temperature of the earth? No; to provide against a very calm day when the wells will not work.

Effect of well-water.

6716. Do you find it detrimental to vegetation to put the water immediately from the well on to the land? No, I find no ill effects from it. The water is put on very often direct from the well. The custom is to water in the early morning and evening.

6717. And you think the water may be taken at all hours from a well of that depth, and placed immediately on the land? I have seen no ill effects from it in my garden.

Temperature.

6718. Have you noticed that the water is of a very high temperature at some times in the well? No, it is of a uniform temperature, I believe—I never remarked any difference.

6719. Did you never remark that sometimes it is much higher than the water in the tank? There is a difference in the temperature of the water in the two places; in the tank the water gets very hot.

6720. But does it not get sometimes very much colder by standing in the tank? It depends upon the weather.

6721. I am referring particularly to the summer-time? No; it gets hot in the iron tank, I have always found.

Soil.

6722. What is the nature of the soil in your garden as compared with the general soil of the district? It is heavy black soil, the same as that about Bourke.

6723. If you were to plant in the soil in its natural state, depending upon the rain of ordinary seasons, could you cultivate? No, I think not—I am sure not.

Tree-growing.

6724. With the assistance of water you have been very successful in growing trees? Yes, and shrubs and flowers, also a little patch of lucerne.

6725. Will you describe what you have grown with the assistance of irrigation? Principally trees; pepper trees, the Queensland silky oak, the blue gum, the currajong, a plane tree, also two white cedars. They have all grown very successfully.

Mr. F. W. Mackay. 25 May, 1885.

6726. And you have also planted a tree fern? The tree fern has only been planted within the last two months.

6727. But it is growing vigorously? Yes, strongly and beautifully. Roses, I may mention, I have found to do very well.

6728. And you have succeeded in laying grass lands with couch grass? Yes; we tried a small experiment with buffalo grass, but it died, except where immediately watered.

Crops. 6729. After this practical test, are you of opinion that with an enlarged system of irrigation over a large area you could succeed in growing any amount of crops here? My experiments have been confined to ornamental trees, and shrubs, and flowers; but no doubt the Chinamen's gardens here are a proof of what can be done. Tim Yang irrigates from his well with a Tangye steam-engine, and there is a Chinaman who irrigates from the river by means of a pump; both of them have been very successful.

Size of fruits. 6730. Is it not a fact that in growing fruit the sizes attained are of unusual dimensions? Yes; the oranges are of a very fair size. Fruit trees are grown very successfully. I have grown peaches, grapes, and mulberries. The mulberries only were spoiled by dust-storms. Grapes are liable to be spoiled if not sheltered from the hot westerly winds.

Area. 6731. What is the area of the ground that you have treated? About a quarter of an acre.

Quantity of water used. 6732. Can you state approximately the number of hours per day, day by day, that you have pumped on this ground to produce these results? I think six hours a day during the summer months.

6733. 2,400 gallons per day, you think? Yes; excepting Sundays—there is no water put on on Sundays.

6734. Do you think there is any defect in your system which would cause the waste of any portion of the water? There is no waste that I can see, except a small portion that may be wasted on the paths—that is very trifling.

6735. Then we are to infer that that would be a fair quantity of water to distribute over that area for general irrigation purposes? Yes.

Soil. 6736. Do you know if there is any soil superior to yours in other situations, which would retain the water and irrigate with a less quantity? No, I am not aware of any. I may mention that I had three peach trees that had a larger quantity of water than usual; they bore very heavily last season.

Success of irrigation. 6737. So far as you have observed then, you have found that all those who will assist nature by irrigation are successful in establishing gardens? Yes; we have had excellent peaches and grapes; in fact, some of the grapes were sent to Sydney, and were favourably noticed by the *Herald*; they were the red muscat.

Chinamen's gardens. 6738. *Mr. M'Mordie.*] What is the area of the Chinamen's gardens to which you have referred? I could not say. Tim Yang's, I dare say, is 3 or 4 acres.

6739. Do you know what price Tim Yang paid for the land which he now uses as gardens? I have no idea.

6740. *Chairman.*] You know by rumour that he paid a large price? Yes.

6741. *Mr. M'Mordie.*] What price does the rumour say? There was a rumour that he paid some £2,000 for some land on which was a vineyard, but I do not know how true it is.

6742. Was that for the whole 4 acres? No, that was for the vineyard only.

6743. What would be the area of the vineyard approximately? About 1 acre. However, I cannot be sure—I do not pay much attention to rumours.

6744. *Chairman.*] Do you know the number of men employed in Tim Yang's garden? It varies I believe; on an average there are about twenty—I have seen that number there myself, all Chinamen.

6745. But the garden produces fruit and vegetables almost sufficient for the town I suppose? Yes.

Manure. 6746. Do you find that your land deteriorates in any way by constant irrigation? No; this garden of mine, with a little manure, bears very well—everything grows nicely in it.

6747. In what way do you manure it? With horse manure mixed lightly with earth.

6748. *Mr. Barton.*] Do you use that in preference to any other, or is it handiest to get? It is handiest to get.

6749. *Chairman.*] Are you so satisfied with your labours that you would not hesitate to extend the operations over a large area? I should not hesitate.

Mr. Charles Edmund Goyder called in and examined:—

Mr. C. E. Goyder. 25 May, 1885.

6750. *Chairman.*] You are a resident of this district, are you not? Yes, on the Warrego.

6751. Are you a run-holder? Yes.

6752. What is the name of your run? Pirillie.

Losses. 6753. You have been subject to considerable losses by the late drought, I believe? We suffered like the rest.

Water conservation. 6754. But I suppose you have taken means to provide the station with water for the stock? Yes; we conserve water in tanks and dams, and also by a well.

Expense. 6755. I suppose the conservation of water for stock is one of your heaviest expenses? Oh yes.

6756. What proportion would it bear to the general expense of management for the year—say on a block of 100 square miles? It would cost £1,500 to water it—that would be a fair expenditure for that area. It greatly depends upon the facilities you have for making water to begin with, because you may spend £1,000 in one place and not get as much as you would get for £100 in another place.

6757. What is the area of your run in square miles? 370 miles, I think.

6758. So that we may take it that the cost of watering that run would be about three and a half times the amount you have stated? It would cost more at our place I think, because it is a bad country to make water in; there is a great deal of wear and tear on the dams; a dam made there is not a permanency—you have to be always patching it.

Water-rate. 6759. Now suppose a means were adopted to give you a permanent supply, upon a properly conceived plan, I suppose it would be in your interest to pay a water rate, not to the extent of your present expenditure, but a fairly estimated rate, for the use of such water? It would pay us, presuming we had not already spent this money; but having spent the money, we are to a certain extent independent.

6760. Suppose that by a recurrence of droughts your present catchment could not be supplied for want of rain, and you had a supply at hand, would it be worth your while to pay for the water? Yes, it would be fair to pay a fair interest on the expenditure, and a little more, in time of drought.

6761. Suppose that works of that character were in the vicinity of your run, and the water could be used on payment of a charge, there would be no objection to the imposition of a rate? No.

Mr. C. E. Goyder. 25 May, 1885.

6762. If such works were established, what system of management do you think would be best—should it be by local Trusts or by a Board in Sydney? I think it would be better to have them locally managed. Trusts.
6763. So that those interested would have the direction of the distribution? Yes, and you would then get men who thoroughly understand the matter. A great deal of practical experience is required, in addition to scientific theories about water.
6764. What river commands your country? The Warrego. The Warrego.
6765. What is the present condition of the Warrego, after this long drought? Its condition after the drought was very dry. There were three places on the frontage where there was water, but only in consequence of dams.
6766. Where is your run situated with respect to the Warrego? To the north-westward.
6767. Do you conserve the waters of the Warrego at all now? Yes, by means of dams. Dams.
6768. How are they constructed? The earth is excavated and thrown across the channel of the river. Construction.
6769. Are there any dams situated above you? Yes, there are a number of dams between us and the Queensland border. Situation.
6770. Have you had reason to complain of the stopping of a moderate supply of water by the upper dam? No, I find that it is a matter of give and take; sometimes you will suffer, and at other times it will be to your advantage, and I think it is only fair that every one should be allowed to dam in a fair way, but not to stop a river or creek altogether.
6771. Are the crests of these dams carried up to the level of the natural banks? Higher as a rule. Height.
6772. And, in addition, wings are thrown out? Yes; the channel of the river is fully filled, and a wing is thrown out on each side. Wings.
6773. To what distance? It depends entirely on the position. Before making a dam it is necessary to select a place where you can get a by-wash, without having the wings of your dam exposed to the wash of the water. By-wash.
6774. Do not you find these wings throw out a large quantity of water on the flat lands in some cases? In some cases they do; but in selecting a site, you choose one, if possible, where the overflow water leaves the bed of the river at some distance above the dam and runs round the dam at some distance from it, and in again at a point further down; in fact some dams have half a dozen by-washes to them.
6775. Do you think the same purpose would be served if an inexpensive overshot dam could be designed? Yes, but I do not think you could make an inexpensive overshot dam; if you could, it would be the best thing you could do. Overshot dams.
6776. And to have the upper one so arranged that the water might be regulated down to the lower one? Yes.
6777. You would have the main dam overshot? Yes.
6778. And the water regulated so as to give you a supply and prevent any overflow on to the surrounding country? Then happiness would reign supreme on the Warrego.
6779. I suppose it has occurred to you that this should be done, but you do not see your way to do it? No, I do not see my way to do it.
6780. The water at present conserved in the dams is used for stock in the same manner as you use your tanks? Yes. Use of water.
6781. Have you attempted to distribute the dammed water by channels over the back country? No. There is a regular network of creeks on Pirillie, and I have tried to throw water here and there in them. There is one dam used to throw the water out of the Irrara into Green Creek; this creek runs out of the Irrara Creek in a south-west direction and empties itself into swamps, sometimes the very heavy floods reaching the Warrego. Distribution.
6782. Then you have practical proof that, by raising a head of water, it is possible to find a drainage line in a different direction to that of the creek? Yes, I have always found that the level changes in these creeks in a most extraordinary and incomprehensible manner. This dam on the Irrara that throws the water into Green Creek was put there by Sir Samuel Wilson to stop the Irrara and get the water into Green Creek, as that creek never used to run; when it was not there it used to by-wash, and the water still came down the Irrara below it. I put a dam below that on the Irrara, but I find now that all the water goes down Green Creek. I have had to cut the first dam to get mine full. The last time the river ran I was not able to get any water into my dam at all—all the water has gone down the Green Creek. I do not think it is silting, because the Irrara water is very clear always; the change is in consequence of some alteration in the contour of the country. Drainage line. Dam on Irrara.
6783. You had no means of ascertaining the former level before you interrupted the flow of the water? No. Levels.
6784. You have springs on your run, have you not? Yes. Springs.
6785. What is the nature of these springs? They are what are called mud springs—the water comes up through the mud.
6786. Is there any particular feature about these mud springs—are they lifted above the ground in any way? Some of them are, but the ones which have the most water in them are not, as a rule.
6787. *Mr. Barton.*] There is more water and less mud I suppose in some, and in others there is more mud and less water? Yes.
6788. *Chairman.*] Will you explain what means you have adopted to avail yourself of the water of these springs? I put sheep at them just as they were, to commence with. It was always understood that they would carry 10,000 sheep, which of course they did not.
6789. Is not the ground very boggy and loose at the site of these springs? No; they are on the head of Coonbillie Creek. There is an amphitheatre surrounded by rocky mulga ridges. The ground towards the head of the fall is partly covered with rough water-worn boulders, and they are also in the ground, as I have found by sinking.
6790. At present the water is used from the surface? Yes.
6791. How is it got? The source of the springs is through a reed-bed slightly lifted above the general surface of the ground. The water then discharges in an annular basin about 10 feet wide, and the stock can water there without fear of bogging. Stock watering.
6792. Is it a permanent supply? Yes, it is permanent, but limited. Supply.
6793. Have you ever tried to sink a well near the site of one of these springs? Yes. Well.
6794. In what way did you form your well? I tried to sink shafts with slabbing.

6795.

Mr. C. E. Goyder. 25 May, 1885.

6795. What was the result? Mud. In one well I got a little water—about 1,000 gallons a day.

6796. Then you are not aware that any one has ever succeeded in getting pure water at the site of the springs? No; there is a well at Goonery, but I do not think it is in the mud. They have never been successful at Coonbillie.

Flow. 6797. Did you ever trace the flow of this water to a lower level in better ground? No, I cannot trace it anywhere out there.

Storage. 6798. And do you think that any means could be adopted by which that water might be clarified and stored? Yes.

6799. In what way? By putting down a pipe until you get the clear water. There is no doubt that there is plenty of water, or it would not be forced up through the mud springs. Not only is there a great deal of water, but there is also a great pressure.

6800. Has a tube well ever been tried there? No, not at these springs.

6801. Nor borings of any kind? No.

Source. 6802. Have you ever formed an opinion as to the source of these springs, whether they arise from the bed of the river or from local soakage? I do not think that the water is supplied by local soakage; it must be collected from some place where there is plenty of it, because there must be very great pressure underneath.

Groups of springs. 6803. What is the extent of country in miles in which these springs are situated? There are three groups of springs. One consists of only a single spring, and has no name; it is at the north-west corner of Glenelg. Then there are Barlungma Springs.

Situation. 6804. These springs are very near the ridge country? Yes; the big, rocky mulga ridge. That is in the south-west of the Mutagoona back block. The Coonbillie Springs are in the south-east corner of Coonbillie block. There are other springs to the east of the Warrego, at Leila woolsheds; they give a big supply. There is another spring to the east of the Warrego, in the same line, below Leila House. A map showing the localities of the springs may be obtained at the District Surveyor's Office, Bourke.

Watershed. Boring machine. 6805. What means would you recommend to prove the extent of this watershed? I should think a really first-class boring machine could cope with all the difficulties; but it must be something better than I have seen up here yet.

6806. And which in your opinion would be the best site to make the boring? I do not think my experience is sufficiently large to enable me to answer that question.

6807. Is there a gentleman out here who has been experimenting with bores for some time? Yes—Mr. Bignell.

Yantabulla Spring. 6808. Mr. Bignell has been more successful than any one else with the bores he has got? Yes. If it were thought well to test the country, Yantabulla, where a township is about to be surveyed, would be a suitable spot—there is a splendid spring there.

6809. Are you aware that that spot has already been inspected by the manager of the boring operations? No, I am not.

Quality. 6810. Generally, so far as you know, the spring water is of good quality, and is fit for all purposes? Yes, I do not know of any spring which is not good to drink.

Supply. 6811. What do you suppose would be the daily supply of the Coonbillie Springs? Not more than 1,000 gallons a day in their natural state—they will not water more than about 1,000 sheep in the summer.

6812. Suppose you exhaust the water during the day, does it make again at night? No, it will not make in very bad weather. You see you exhaust the water in the basin, and a big dust-storm comes up, with the result that the surface of the mud or sponge has a good thick coating of red dust, and no more water goes into it for a bit.

6813. Have you never attempted to protect these reed-beds by building a fence of boughs? No, I did not think it worth while.

6814. Do you find from any ascertained cause a variation in the supply of water in this spring? No, I have seen no appreciable difference.

Well. 6815. Have you by means of wells discovered any underground supply? Yes; I have a well about 50 yards from the Coonbillie Springs.

Size. 6816. What are the natural dimensions of that well? It is a shaft 6 feet by 3 feet.

Slabbing. 6817. Slabbed down as usual? Where necessary.

Depth. 6818. To what depth? Between 35 and 40 feet.

Strata. 6819. What is the nature of the strata through which you passed in sinking the well? Water-worn boulders on the surface to a depth of 7 feet, and there is for 5 or 6 feet a little bit of rock, having pebbles through it, as if it had been crushed into one mass—a conglomerate. Then you have the water.

Quality. 6820. What is the nature of the water? Very salt. It is good stock water as we call it, and that is all.

6821. Did you shut it out? No; I wanted it.

6822. Then you went to a greater depth? Yes, until I could not keep the water down. It was the same water all the way; it was in a compound of chalk and pipeclay.

Supply. 6823. You made no attempt to get below that water? No. There is a good supply there of about 6,000 or 7,000 gallons, which sheep will drink when they get used to it.

6824. Did you ever exhaust that well? I have never used it; it always rains when I begin to use that well.

Shaft. 6825. Have you any other wells in the neighbourhood of it in which you find fresh water? No, except a shaft in Barlungma Springs. There are about 1,000 gallons a day obtained from it. It is 20 feet deep, and the water is found in a brown rotten stone which appears to me to be like solidified mud.

Supply. 6826. And if you were to draw in excess of that quantity per day the shaft would become dry? Yes.

6827. And by percolation would fill again? Yes.

6828. In what time? About eight hours, I think.

6829. Then there would be about 3,000 gallons in twenty-four hours? No; the shaft scarcely holds 1,000 gallons of water; it is a very little shaft. It would not yield more than 1,000 gallons in twenty-four hours. I have never tried it, so that it is merely a matter of conjecture.

6830. It does not offer you sufficient inducement to sink a larger well? No; I used to use it mostly for horses.

6831. Have you any other wells on your run which are more successful? No.

6832. *Mr. Barton.*] Does it strike you that the water in this well has anything to do with the mud springs? It is a different supply altogether—quite different water, and on a different level; the well is on a hill.

6833. Do you know the source of the Warrego? Not at all. Mr. C. E. Goyder.
6834. You have tanks in various positions over your run? Yes.
6835. And do you find generally that the land is retentive? Yes, if you are very successful in picking a place, but I find great difficulty in getting down; you get 8 or 10 feet of clay and then salt water; I have put down as many as eighteen shafts before I got a piece of clay deep enough to put a tank in. 25 May, 1885. Tanks.
6836. Your tanks have been recently filled, have they not? Yes, most of them.
6837. Do you attach any kind of gauge to your tanks to ascertain the loss by evaporation, soakage, &c.? No; I have no idea what the evaporation would be, but I may say that, as far as my experience goes in that country, if you can get suitable places to make dams they are the best—they are better than tanks. The water contained in tanks does not last like water in dams. It is wonderful how the dams hold out in the drought. The dam at Willyeuroo stood all through the drought. Evaporation. Dams versus tanks.
6838. *Chairman.*] Do you think there is a great waste of water in the first charging of the rivers, from the fact of the beds being dry, a great deal of soakage taking place? Yes, especially in big creeks—more than in the rivers. Soakage.
6839. Then, in designing a system of dams, it would be of advantage to keep the beds always moist, if possible? Yes, decidedly.

Mr. Thomas Topham called in and examined :—

6840. *Chairman.*] You have lived in this district a length of time? Yes—twenty years. Mr. T. Topham.
6841. And your experience has taken you over the system of rivers in this district? Yes.
6842. Taking Bourke as a centre, within what radius can you give us any information up and down the rivers? I have been pretty well round the Wilcannia district, and up from there to the Namoi and the head of the Bogan—all round the Narran, Paroo, and Warrego. 25 May, 1885.
6843. You are acquainted with the formation of the Darling generally as far as the Namoi? Pretty fairly. The Darling.
6844. On both banks? I have been on both banks, in both floods and droughts.
6845. You know there are very large billabongs on this river? Yes. Billabongs.
6846. Do you know any billabongs such as the Cato Creek on the Barwon, and a series of billabongs of very large extent on the north-western side of the river? Yes.
6847. Do you know if such billabongs or depressions exist on the south-east side of the river? Yes, there are some smaller than those on the other side.
6848. Can you particularize any large billabongs on the south-eastern side, between the Namoi and Bourke? Not on this side; all the way down from Walgett to Brewarrina on this side it is one extent of flat country.
6849. You do not know of any deep depressions? I do not know of any particular ones. I have ridden over the country right across from Walgett to Canonbar, and it was all under water.
6850. Do you know that the principal creeks discharging into the main river are comparatively flat? Yes, there is no fall.
6851. You have seen the dams fixed on most of them, and know the nature of the dams? Yes. Dams.
6852. You are aware that these dams throw the water back for a long distance with a slight elevation in the dam itself? Yes, 6 or 7 miles. Back-water.
6853. What height of dam would be required to do that from the bed of the creek to the bank level? 20 feet. Height of dams.
6854. Then a rise of 20 feet only throws the water back 6 miles? Yes.
6855. But that is contrary to the evidence you gave just now that there was no fall in the creek? The site chosen for the dams is generally a very favourable spot, where there is a bit of a channel, perhaps the site of a waterhole. Site.
6856. Then, when you say 20 feet, you mean that that height would be caused by the dam being situated in a depression? Not altogether, but by being above the surrounding country.
6857. Do you not think it a disadvantage to throw water on to a flat country at the side of the creeks? Yes, because you simply keep it there for waste. Inundating flat country.
6858. Do you not think it would be an advantage to build overshot dams at a lower level, and at more frequent intervals—would not they retain permanent water? They would if properly constructed, and sufficient money were expended in making provision against their being carried away, but I have seen so many on which a lot of money has been spent, and which are perfectly useless. Overshot dams.
6859. Have you seen any successful overshot dams? Yes; there is a very good overshot dam at Dumble, and there is another just below that, at Mr. W. Doyle's station, Muckrewagh.
6860. Can you describe the construction of the dam? It is made of ordinary timber, I think clear pine, and it is considerably below the level of the top of the bank. Construction.
6861. What would be the height from the bed of the creek to the crest of the dam? I should think certainly not more than 12 feet, standing on the bed of the creek. Height.
6862. Can you describe the construction of it—how it is framed up? You can get a description of it from Mr. Francis Bacon, the partner with Wright, Heaton, owners of Dumble Station. There is another dam on Charlton Station on the Bogan, a very successful one; it has stood for years.
6863. Where can we get a description of that dam? From Mr. Russell Barton, or Mr. Macintosh, the manager of Charlton Station.
6864. Do you think that, with proper surveys and examination, a general system of water conservation could be carried out superior to that of private enterprise? Yes, most decidedly. Water conservation.
6865. And you think that very great improvements might be made on the present system? Yes, very easily. Improvements.
6866. Do you think the present system by private enterprise is carried out to the fullest extent? No, not to the fiftieth part.
6867. Do you know of any reason why greater exertions are not made, or have not been made? Yes, I think so.
6868. What are they? Security of tenure for one thing; another reason is that the stationholders, as a rule, do not hold their stations more than four or five years. Those who are more successful hold them for a lifetime, but the majority of men keep them only five or six years, and run up everything as cheaply as possible. Security of tenure.

Mr. T. Topham. 25 May, 1885.

6869. Then you think the means employed by them could be greatly improved upon so as to bring about much more satisfactory results? Yes, I am sure of it.

Diversions.

6870. Can you yourself suggest a better means of conserving water? I think there are endless instances where you could find out where you could divert the streams in this flat country, and spread the water, instead of allowing it to run down into one channel in the Darling.

6871. In what way would you do that—would you raise the ordinary water level in the rivers? I would retain the waters to nearly two-thirds of the flood level, so as not to throw it on to the flat country.

Natural depressions.

6872. Do you know, from your great experience in the district, that there are natural depressions in the valley of the Darling which could be formed into reservoirs for the catchment of the great flood-waters? Yes, I do.

Storing flood-waters.

6873. Then you think that, by a close examination and survey of the river system, portions of the high floods could be held back and afterwards liberated at will? Yes.

6874. Are you prepared to mention any exact localities? I think that if a lock were put at the junction of the Bogan and the Darling it would drive the water back for miles in the Bogan River, and Dry Bogan, and the billabongs all over the place. There would be a network of water. I also think that there is a very good place at Belalie Station (Mr. W. Scott's) that would throw the water back as far as Barrungun township, and all over the country for miles around. This would be of the greatest service to the district, as during this last drought there was very little water left, and, if rain had kept away for (say) three months longer, the stations all round and the Barrungun township also would have been deserted.

6875. That would be back water from the river? Yes.

The Macquarie.

6876. Do you know the Macquarie? I do.

6877. Do you know the Macquarie at the site where the water discharges from the defined banks into a swamp? Yes.

6878. Do you know the country between that site laterally to the Bogan—between the Macquarie and the Bogan? Yes.

6879. Do you know that a line crossing in that direction would bisect three or four creeks? Yes, dozens that have no name; in fact, there would be a perfect network.

Diversion.

6880. Do you think that upon survey a line of canal could be formed so as to divert the Macquarie into the Bogan in that direction? Yes, I am sure of it.

6881. And such a canal, with properly designed sluices, would discharge the waste waters of the Macquarie into the heads of those creeks again, if necessary? Yes.

6882. Then, if the waste water which is now carried over that large area of swamp were thrown into the Bogan, then, by the construction of dams in the Bogan to receive that water, a very large area of country would be supplied? Yes.

The Narran.

6883. Do you know of any other systems of creeks that might be treated in the same manner? I think the Narran basin might be treated in the same manner.

6884. Do you know the source of the Narran? I do not know exactly, though I have been all about the Narran.

6885. You do not know whether the head of the Narran in Queensland could be treated so as to conserve water for its supply? Yes, it is deep enough there, and has well-defined banks; up at Bangat it is a well-defined river.

6886. You are aware that the Narran sometimes discharges beyond the capacity of its natural channel? Yes.

6887. And do you think that if the water could be retained for a time at the head of the Narran in Queensland that that river might also be supplied? I think that all the west country, round about what they call the Narran Lake, might be supplied from the water that you would conserve above.

6888. Do you think that the water at the end of the Narran, before it discharges into the lake, could be intercepted and conveyed in another direction through the dry country between the Narran and the Bokhara? Yes, there is every facility for it.

6889. Do you know by indications that that is the drainage line towards the Bokhara River? Yes.

6890. Then, by diverting that waste water, a very large tract of country now dry could be supplied? Yes.

The Narran Lake.

6891. Have you any idea of the size of the Narran Lake when fully charged with water? I could not tell; it is miles round.

6892. But it is a shallow lake? Yes, it is like a vast plain.

Evaporation and soakage cracks.

6893. Evaporation and soakage take place quickly, and the water is quickly lost? Yes; there are immense cracks in the earth.

6894. But that volume of water, conveyed in a defined channel, would be comparatively permanent? Yes.

6895. Otherwise it is lost? Yes.

The Paroo.

6896. You know the Paroo River? I do, well.

6897. Do you know its source or its line above Hungerford? Yes; it runs some scores of miles above Hungerford.

6898. Do you think that the upper portion of that river in Queensland could be treated so as to conserve a portion of the water in a manner similar to the Narran? I think the Paroo could be much more easily treated.

6899. The water in the Paroo is largely availed of by means of dams throughout its length? Yes.

6900. But at its lower end it discharges into a large system of lakes and swamps? Yes.

6901. You do not know the area of that country which is now made useless by that network of swamps? I do not.

6902. Do you think it is worthy of inquiry whether that water which is now wasted in the swamps could be directed through another line of country and be made available towards the Darling? Yes, I think that is one of the grandest schemes out.

Narran Lake.

6903. You do not think it would be of any advantage to raise a levée or bank to increase the depth of the Narran Lake? I do not know whether it is possible or not; but I should think it is possible to raise the height very much, and it would still be a very shallow lake.

6904. Do you know the country between this and Cobar? I do.

6905. Have you formed any idea as to the drainage lines from the Darling and the Bogan towards Cobar? Yes; the drainage is from Cobar towards the Darling and the Bogan.

6906. *Mr. M'Mordie.*] Is there not a ridge between Cobar and the Bogan? Yes; there is a line of low hills.

TUESDAY,

TUESDAY, 26 *MAY*, 1885.

At Bourke.

Present:—

MR. BARTON, M.P., | MR. FRANKLIN, C.E.,
MR. M'MORDIE, M.I.C.E.

F. A. FRANKLIN, ESQ., C.E., IN THE CHAIR.

Mr. Christopher Brandis called in and examined:—

Mr. C. Brandis. 26 May, 1885.

6907. *Chairman.*] You have the management of a large station? Yes; Beemery Station.
6908. What is the extent of that station? About 400,000 acres.
6909. That is situated on the south-east bank of the Darling, at what distance above Bourke? The nearest boundary to Bourke is about 15 miles distant.
6910. By the river line? It is more, taking the windings of the river; it would be more than 25 miles that way.
6911. What has been your experience in the management of the country? In what respect?
6912. In regard to seasons, and the general difficulties which have arisen from bad seasons: how long have you been there? Eight years. The largest flood I saw was in 1880. Seasons.
6913. During your experience you have had excessively dry seasons? Yes, I had two, one in 1877-8 and the last season.
6914. Over what periods did the dry weather last? In the first case it was about eighteen months, and in the last you may say that the bad season lasted for something like two years—really bad.
6915. I believe you keep a correct register of the rainfall on your station? Yes, I do.
6916. Can you tell me what the rainfall has been during those periods? The average was a little over 14 inches. In 1877 it was 10·21 in.; in 1878, 16·63 in.; in 1879, 17·54 in.; in 1880, 18·15 in.; in 1881, 16·74 in.; in 1882, 20·10 in.; in 1883, 9·98 in.; in 1884, 7·97 in. Rainfall.
6917. Taking the mean of that rainfall, is it considered below what is necessary? Yes, very much below.
6918. What quantity of rain would you consider necessary for the cropping of this country—to keep this part of the country supplied with fodder? I think it would take 35 inches of rain to make fodder grow here; it also depends very much on how the rain falls. Crops.
6919. The natural rainfall is unreliable for the purposes of stock? It is.
6920. Will you tell me what means you adopt for the conservation of water on your run in the absence of rain? We have tanks. Tanks.
6921. How many tanks have you? Eight.
6922. What is their mean capacity in cubic yards? About 8,800 yards. There are some small tanks. Capacity.
6923. Then, with 71,000 cubic yards of excavation, you store what you consider a sufficient supply of water for your stock? No.
6924. Then, have you any auxiliary means for supplying the stock in case of extreme drought? I have given you the whole of the tanks on the run; but we have the Barwon and Bogan Rivers. Any tank under 12,000 yards is almost useless in this country.
6925. But I want to know if 71,000 cubic yards will not supply your run, what other means you adopt for the further storage of water? We put catchment dams on the Bogan—small, rough things. The Bogan runs through the run. Dams on Bogan.
6926. Will you tell me in what manner you construct those dams in the Bogan? We put small earth dams to catch the last of the floods. The Bogan only runs occasionally. The dams are of very temporary construction. Construction.
6927. Do you select a spot for erecting those temporary dams where the water does not flow in any volume? We select the shallowest part of the river. The river is a series of shallow holes; at one part the river is much deeper than at another; we put rough catchment dams in the shallowest parts. Site.
6928. What is the result of the construction of these temporary dams in the river? By erecting small dams, which are perhaps only 3 feet high, we get water for three or four months longer than we otherwise should; they back the water into the bed of the river. Result.
6929. To what distance? In some instances it goes back about 2 to 3 miles. Backwater.
6930. From that we may conclude that the fall of the river bed is 1 foot in a mile? Somewhere about that, I think, in many cases. Fall of river.
6931. In bringing your stock to water, you use the river as a more permanent means of supply than the tanks? Yes; of course, in the back parts of the run we have many paddocks with no river frontage, and there we have to use tanks. Watering stock.
6932. Do you think you take a larger proportion of water from the river by means of those temporary dams than is taken from the tanks in the back part of the station? Yes; that is, on the Bogan.
6933. Would you consider that you double the supply of water on your run by your dams in the river, taking a period of years? We could double the supply in those paddocks by properly-constructed dams. Supply.
6934. So that in the aggregate you have about 71,000 cubic yards of water as a standing stock every year? Yes, for those paddocks that are dry. There is only a small proportion of Beemery Run that has no river frontage, comparatively speaking.
6935. Do you find in the erection of these temporary dams that the water has a tendency to rise above the level that you bar off? Yes. Rise of water.
6936. How do you provide against that contingency? We make a small by-wash, picking an island in the bed of the river, and try to get a by-wash to let the water run round. By-wash.
6937. Have you found that sufficient at all times? It is not sufficient. I propose to put good overshot dams in the Bogan. Overshot dams
6938. There are many parts of the Bogan situated as you state, running on the frontage of runs, where overshot dams properly constructed would be of very great service to the runholders? They certainly would.
6939. And if they were placed in positions properly selected with regard to the fall of the slope of river, you would have almost permanent water throughout its length? Yes, you may say we should have permanent water without injury to any one.

Mr. C. Brandis. 26 May, 1885.

6940. At what height do you think those dams would be serviceable to the runholders without being detrimental to the ordinary flow of water in the river in times of flood? I think, in suitable places, 6 or 8 feet would be ample.

Height and length.

6941. With a rise of 6 or 8 feet, what would be the average length of the dam to touch the solid bank? I should think from 100 to 120 feet. I am speaking of places that one could pick in the Bogan—places that I am particularly well acquainted with in the lower part.

6942. Then that height would throw the water back in the ratio of the fall of the river, which you say is 1 foot in a mile, or 6 miles behind each dam. Yes, if suitable places were selected.

Low-level overshot dam.

6943. Do you know of any low-level overshot dams of a more permanent character in the Bogan? Yes, I know of one just above my boundary.

Construction.

6944. How is that constructed? It is constructed of piles and stones. The first design was defective, but by constant repairs by carting clay and stone they have made it a very good dam, and permanent.

6945. The silt brought down by successive floods tends to make it tighter? Yes.

Erosion of banks.

6946. Are there any signs of erosion of the banks at the wings of that dam? Not a great deal.

Flanking of dam.

6947. There is no positive tendency to flank the dam—that is, to change the direction of the current? No, there is not; the whole thing is constructed so queerly. I think the stone would have prevented the washing away of the bank.

6948. Then I understand that there is a rough sort of revetment at the flanks of the dam formed by stones pitched to the natural slope, and that this proves sufficient to prevent any flanking of the dam? Yes.

Height.

6949. What is the height of that dam? Originally I should think it would be 6 or 8 feet.

Flow.

6950. Do you think that properly designed and constructed dams built in suitable places would not interfere with the flow of the flood-water? No, not at all.

Floods.

6951. Or raise the height of the flood level? I do not think so. As a rule, when a flood comes down the Bogan it is a good high one, and comes down with great force, and after filling the dams would pass on down the river. I may state that in the dam I have just spoken of there was water throughout the whole of the last drought.

Bogginess.

6952. Do you find that in retaining the water behind these dams for a great length of time the margin becomes dangerously boggy for cattle? Not when the water is in the bed of the river. Some places are boggy, but it is not the rule.

6953. So that you find no objection to them in regard to stock in a weak state becoming bogged when seeking water? Of course sheep during a drought get into such a weak state that they cannot get out of even a few inches of mud, but sheep in fair condition can easily get out.

6954. You do not adopt any system of fencing off dangerous places? We do not on the Barwon—there are no places fenced off on the Bogan.

Supply in dams.

6955. During the dry seasons you have mentioned, have you always had sufficient water flowing into the Bogan to keep your dams properly filled? Our catchment dams have not been sufficient to keep a permanent supply of water.

6956. Have you always been able to keep your dams in the Bogan filled when you have had light rains? They have been filled, but with a heavy flood our catchment dams have been washed away.

6957. Supposing the system I have suggested of making a continuous step of dams all the way through the line of the Bogan were carried out, would the present supply of water fill a succession of dams? Certainly, from my experience of it; that is to say, I think that the dams we are speaking of would retain water for from nine to twelve months.

6958. Therefore it would be of great advantage along that line if a continual supply of water could be given? Yes, but I certainly object to full bank earth-dams.

Diversion from the Macquarie.

6959. You know the country between the Macquarie and the Bogan—the country that bisects Duck Creek and those other creeks that run that way? I have travelled over it many times, but I do not know it well.

6960. If it were possible to check the water that is now discharged over that country—the Macquarie swamps—and convey it into the Bogan on a cross line, and so regulate it at all seasons, that would be an advantage to a great extent of country? Certainly it would.

6961. And at times, I suppose, that discharge from the Macquarie would be more than the Bogan could bear? Yes, I think so.

6962. Unless portions of it were regulated down into the natural outlets that now exist, such as the Duck Creek, the Crooked Creek, and the Middle Creek? Yes, I think the Bogan could not take all the water. When the Bogan is in flood it spreads over miles of country itself, but I cannot tell you much about that line of country.

Supply of the Darling.

6963. Do you know whether the flow of water into the Darling from the Bogan and the Culgoa and other rivers is as much now as formerly? From my recollection it is as much now as it has ever been.

6964. You do not know that the dealing with these rivers by dams has at all influenced the discharge into the Darling? I do not think it has, except some large dams on the Upper Bogan; but some of the largest dams on Culgoa were put up before I came into the district.

Back-waters.

6965. During the flood that you have mentioned as the highest, to what extent did the flood-waters back on to your run? I should say about 10 miles from the river line.

6966. Was it shallowest close to the bank of the river—did the actual bank of the river stand out in hummocks and ridges? Yes; the whole country occupied by the flood was a series of islands, as it were.

6967. Would you say that you had 10 miles of still back-water over the whole length of your frontage? No.

6968. Over what proportion? It went out to a point. I should think it might average 2 or 3 miles wide.

6969. What would be about the depth of the back-water? It would be impossible to give the depth of it. In many places it would be from 15 to 20 feet in the depressions, and perhaps not more than half an inch running amongst the grass.

6970. What proportion of that flooded country would be about 15 feet deep? On Beemery Run there would be 40 or 50 miles of billabong averaging from 10 to 12 feet deep.

6971. If these deep basins of water were dammed in and secured, would they not keep permanent water for you at a higher level than the river bed? Certainly they would.

6972. And they simply require examination to fix the point at which they should be shut and regulated? Yes. I should state that most of these billabongs are near the river, that is, within a distance which the sheep could travel to the river Barwon for water.

Mr. C. Brandis. 26 May, 1885.

6973. Would you estimate the water in these billabongs to be of more value to you than the grass which would grow on the same area? Yes, in the deeper billabongs.

6974. In connection with the shutting off of these billabongs to impound water, would it be of any advantage to you for grazing purposes to build levées or embankments to shut out the shallow line of inundation? It would be of advantage to us, but it would be too costly. Levées.

6975. But suppose the country could be eased of its very heavy floods at the source above so as to reduce the maximum height, and prevent your being flooded by the increased volume in the narrower channel, would it be of advantage if the general drainage below was regulated by levées on the shallow parts of this country? It would be of advantage.

6976. So long as your impounded waters did not rise to higher levels by contracting the flood-waters into narrower channels? Yes; an immense amount of water could be taken from the Barwon and stored for any purpose in what is called the Dry Bogan. Storage in the Dry Bogan.

6977. Can you tell me the principal source of supply to the Dry Bogan? The Bogan itself; but only in times of extreme flood, and when the Barwon is high at the same time. The Barwon itself, when it rises to top of banks, will send water back up the Bogan for 20 miles. Source of supply.

6978. If the Dry Bogan could be impounded, could a drainage line be found in the direction of the county of Cowper, at the back of Oxley's table-land? No; the country round Oxley's table-land is higher than the Dry Bogan. Drainage line from the Bogan.

6979. Could it be taken so as to connect with the Mulga Creek? No.

6980. Or could it be led in a course somewhat parallel with Bourke, so as to run at the back of Bourke, and so into the Darling again? That might possibly be done, but I should not like to say. The greatest benefit of it would be in connection with the system of conservation of water on the river Barwon itself.

6981. What do you think is the length of the Dry Bogan from its inlet to the Bogan proper, or to that line which would be the back line of floods in the Barwon? Roughly speaking, 25 miles, following the Dry Bogan. Length of the Dry Bogan.

6982. What would be the mean average width of the river, then, between its upper banks as a basin? 200 feet, I should think. Width.

6983. And the slopes are generally natural—not forced up by the strength of the current? They are natural slopes. Slopes.

6984. That river from its formation, you think, has very little fall? Very little; but still I think it has more than the Bogan itself. Fall.

6985. Can you give me an idea what the fall would be in those 25 miles? Making a guess, I should say 26 feet perhaps.

6986. So that two dams in its length, say of 12 or 13 feet, would impound the water throughout the length of the Dry Bogan? Yes. Dams.

6987. That would make a permanent supply of water for that part of the country? Yes, but running parallel to the Barwon a few miles distant. Supply.

6988. Do you know of any rocky bars across the Barwon within the limits of your run? Yes; there are two—one is a bar; in the other case there is rather a deep channel between the rocks. Rocky bars.

6989. Have you ascertained by any means the run of the stone in the country on either side of the river? I have not.

6990. Do you know of any such bars above or below you in the vicinity of which a supply of stone might be obtained? No, except at Brewarrina. The Oxley table-land is about 20 miles away from those places I have mentioned. Supply of stone.

6991. Is there any loose stone in the neighbourhood of those natural bars? No.

6992. No attempt has ever been made to raise the water by means of stone weirs? No; that would impede the navigation of the river. I am speaking of the Barwon now. Stone weirs.

6993. You have never observed whether these bars exist along with the stone in the bank? It certainly does not appear above the surface of the ground on the banks.

6994. It does not crop out on the bank? No; it is not seen on the slope of the banks.

6995. Does it appear as if the floods have acted on that part of the bed of the river? Yes; it is water-worn. River bed.

6996. You have never selected the site of one of these bars for the erection of one of your temporary dams? We have not made any temporary dams on the Barwon; they are all on the Bogan. Temporary dams.

6997. Would it be possible to erect these temporary bars on the Barwon? As a matter of fact, the river was only dry in 1878. At West Bourke the Barwon was then dry for over a quarter of a mile, and there was just a narrow strip of water in the Barwon near the junction of the Culgoa—you could step across. Supply in Barwon.

6998. If it threatened to become almost dry, would you venture to put temporary dams in the main river? No, I have never seen any advantage to be derived from doing so.

6999. You mean you have never seen the possibility of its running as dry as the Bogan? I have never seen the possibility of its becoming dry through its whole length; it has always had plenty of water for stock.

7000. Do you water any part of your run by means of wells? No.

7001. Of course the storing and conservation of water for stock is a large expense in the management of a station? It is. Cost of water conservation.

7002. What proportion do you say it would be on a run of 100 square miles of dry country? I could hardly say. I should think that the expenditure on a 10-mile block would be £3,000 or £4,000.

7003. In view of that very large expenditure, do you not consider that it would be of great advantage to have a general system of well-regulated supply for the country? Speaking of the whole district and not of Beemery Run in particular, I should think it would.

7004. And if such a system of supply could be established, under what system of management would you consider that it ought to be placed—under the direction of local Boards, or of a Sheep Department in Sydney? I should say local Boards, certainly. Local Boards.

7005. Could you suggest in what way these Boards could be formed so as to ensure the most complete supervision of areas of country? At a moment's notice I could not suggest anything. I should say that the Board should be appointed by the leaseholders, but I could not suggest any system on the spur of the moment.

7006. Do you think it would be of advantage that a central Board should be formed consisting of members appointed from the local Boards? I think it would. Central Board.

Mr. C. Brandis. 26 May, 1885.

7007. Do you think the whole matter of water conservation is of such importance that legislation with regard to it is absolutely necessary? Speaking of this district, I certainly do.

7008. Have you anything to suggest that I have not already led up to by questions? No, I think there is nothing I could suggest.

Tarrion Creek.

7009. *Mr. Barton.*] You know Tarrion Creek, at the back of your run? Yes; it branches from the Barwon above Brewarrina, and goes through Charlton Run and part of Beemery Run to the Bogan, about 20 miles from the junction of the Bogan and the Barwon.

7010. Does not the Tarrion, in its lower part, die away as it were; does not the water run out into flats? Yes; you can see the creek, but there is very little in it.

7011. Would it be possible to improve that creek in any way so as to prevent the water from flooding the adjacent country, and so run more water into the Bogan in time of flood in the Barwon, at no very great expense? Certainly it would.

Dam.

7012. And is there any place on the Tarrion where, if a dam were constructed, it would conserve large quantities of water for a long time? Yes.

Size of tanks.

7013. From your experience, what size of tanks would you consider permanent for the number of stock that should, with good management, be depastured round it? Tanks of about 20,000 yards.

Form.

7014. And what is the best form in which to sink the tanks—I mean the best shape and the best batter? The greatest advantage is in having the tank as deep as the ground will possibly allow, with as steep a batter as you can have without the sheep destroying it.

Evaporation.

The evaporation is something tremendous.

Batter.

7015. Do you think it would be any improvement, and if so, would it be worth the outlay when sinking a tank for the supply of stock, to make it with a batter of (say) 1 to 1, putting the earth together on one side and forming in it a brick supply-tank with troughs, using a windmill to fill it, and never allowing the stock to go into the tanks? It would make the supply last much longer, and make a small tank answer the purpose of a larger one; but there is one thing against it—sheep do not do so well at troughs as at open water.

Supply in Barwon.

7016. With reference to the Barwon River, in your experience have you always found that there was sufficient water in the Barwon for stock purposes, and that it would be a needless expenditure of money to attempt to improve that river for stock only? There has always been sufficient water in the Barwon for stock, and any money spent on that river for stock would be simply thrown away.

Railway and navigation.

7017. It has been suggested that it would be of great benefit to the district and to the squatters on the banks of the Bogan if the Barwon were locked so as to make it navigable: I want to know whether, supposing that a railway could be constructed 100 miles up and down from Bourke, at £2,000 a mile, that would not be cheaper and better than locking the Darling in any way? Yes, I think it would.

7018. Do you know anything of Nellie Springs, or any of those springs at the back of Warraweena? I do not know much about them.

Straightening of Barwon.

7019. *Chairman.*] Can you tell us if, on the part of the Barwon River that you know well, there are any extreme points of the river where by a slight cutting a direct channel could be made? Yes, there are some.

7020. Do you think that a moderate-sized cutting there would enlarge during flood-time, and so straighten the course of the river? I think that a cutting made in the river would enlarge in flood-time.

7021. And the result would be a more direct flow of water, and the old bend of the river would then form a billabong? Yes, I think it would, and it would probably silt up at the mouth.

7022. Then, does it not occur to you that the present billabongs were formerly bends of the river? Some of them were undoubtedly.

7023. Their course and the timber on the banks would indicate that they were? Yes.

7024. Do you know a place where the bends of the river are so near each other that by a straight cut in the direction of the stream of about 60 chains you would avoid a deviation of about 7 miles? Yes; between Beemery and Bourke.

Width of Barwon.

7025. Then that might be used as a conserving basin? I should think so.

7026. What is the width on the top? 250 feet, I should think.

Depth.

7027. And the depth from the top of the bank to the bed of the river? About 30 or 40 feet.

Impounding basin.

7028. Then, in the natural course of silting up the old entrance to the river course, this would make an impounding basin of very large capacity indeed? Yes; but the river would not silt up to the full height of its banks.

7029. What I mean is, that by locking the two inlets of that large bend or billabong which would be then formed, an impounding basin of enormous capacity could be formed? Yes.

Evaporation.

7030. Have you adopted any means on your run to ascertain the evaporation in the tanks? No.

7031. You take general observations for the Astronomer, I believe, on your run? Yes.

7032. Would you also undertake to observe the evaporation, if proper instruments were supplied to you? Yes, I should be most happy to do so.

Diversion from the Macquarie.

7033. *Mr. M'Mordie.*] You have given some evidence as to the practicability of intercepting the water of the Macquarie above the Marshes, and of turning them into the Bogan? I said I was not sufficiently well acquainted with that country to give an opinion.

7034. If those waters were so intercepted would it be practicable to provide a permanent water frontage along the Mara Creek? I am not sufficiently well acquainted with that part of the country, and would rather not give an opinion about it.

Mr. Mark Tully called in and examined:—

Mr. M. Tully. 26 May, 1885.

7035. *Chairman.*] You have resided a long time in this district? No; only four years.

7036. Are you a runholder in the district? Yes.

7037. Where is your run situated? Directly opposite the Beemery Run. It is Warraweena. The western boundary of the run goes below Bourke. The West Bourke township has been cut out of a corner of the run.

7038. Do you know all the country between the Culgoa and the Warrego? I have never been outside my own boundaries.

Billabong.

7039. On which river do you depend for your supply for stock purposes? The Barwon and the Culgoa.

7040. Have you any creeks running from the Culgoa which are not clearly shown on the map? There is a large billabong, which runs from the junction of the Culgoa, and enters the Barwon again 15 miles lower down; it is called the Warreena Billabong.

7041.

Mr. M. Tully. 26 May, 1885.

7041. Is that billabong generally dry when the river is low? Yes, except in one or two places—it empties as the river falls.
7042. Would the water obtained in that billabong be of any advantage to you? So much so, that I have erected a dam across with a view of retaining it.
Dam.
7043. Is the dam erected across the inlet? No; about 5 or 6 miles below the inlet.
Height, capacity.
7044. What is the height of the dam? It is about 20 feet. There have been over 10,000 yards of stuff taken out of it.
Overflow.
7045. How do you admit the water into the billabong? From the overflow of the Culgoa and the Barwon.
Current.
7046. Is there any current there likely to disturb your dam? No; the current is very little, on account of the bed of the billabong being so much higher than the bed of the river.
Depressions.
7047. How do you convey water round the dam? By natural depressions in the surrounding country.
7048. The dam is higher than those depressions? Yes.
Lagoons.
7049. What is the nature of the lower end of the billabong? Very flat; there are three or four deep lagoons. There is like a chain of lagoons, with wide shallow flats between them.
Impounding.
7050. What work do you propose to do to impound the water to the level of your dam throughout the length of the billabong? I should think that an overshot dam at the outlet would be the most likely means of impounding it.
7051. I understand that an upper dam has been built? Yes.
Flood.
7052. Have you yet seen the result of a flood from the river? Not since the erection of the dam.
Levels.
7053. Have you done any levelling there to ascertain how the contour level would correspond with your dam? No; I have examined it carefully with a view of damming the water into the billabong from the Culgoa, but I have not taken any levels.
Outlets.
7054. You feel sure, having erected that dam, that there are no outlets at a lower level? Of course, the by-wash is at a lower level than the place where I erected the dam.
7055. But I mean at the lower end of the billabong, are there any depressions lower than your dam? Yes.
7056. So that you could not impound the water to a greater height than the lowest place at present? The water at the lower end of the billabong would run into the river again. The only way to impound it would be by erecting a dam to prevent the water from running into the river as the river falls.
Overshot dam.
7057. What do you consider should be the nature of the dam to be constructed there? I should think an overshot dam would be the only one.
7058. Have you fixed on any design? No; I have never erected any overshot dams.
7059. So that you have not completed your intentions yet in regard to that matter? No.
Tanks.
7060. What do you do for a general supply for stock purposes besides getting a supply from the river? I have sunk tanks in the back country.
Area of run.
7061. What is the area of your run? 440,000 acres.
7062. You are still making tanks? No; I have completed all the tanks that I have the means of going on with at present.
Tanks.
7063. What would be the amount of storage necessary for your purposes on 100 square miles of back country? Two tanks of 20,000 yards each.
Expense.
7064. At what expense could they be constructed? At 1s. 2d. per yard.
7065. Considering that large expenditure, a permanent supply provided under a proper system of water conservation and distribution would have a value relative to the expenditure of the run-holders? Yes; certainly.
Water-rate.
7066. And in that case you would consider it fair if a water-rate were levied that would return the interest on the money expended throughout the country on a general system? Yes.
Local Board.
7067. And if such a system could be established after due inquiry, what system of management would you consider best for its upkeep, and for the general distribution of the water so conserved, and for the collection of the water-rates; should it be in the hands of local Boards, or a Department in Sydney? I should say in the hands of local Boards, under the administration of the Government.
Wells.
7068. Have you any wells on your runs? Yes, I have two.
7069. Did you sink them yourself? I sank one myself.
Size.
7070. What are the internal dimensions of that well? 6 feet by 2½, divided into two shafts.
Depth.
7071. To what depth is that well sunk? About 250 feet. The other is about 150 feet.
7072. Are the two wells in close proximity to each other? No, they are 8 miles apart, on the back country.
Quality.
7073. What water do you get from them? The water in the 250-feet well is very salt, totally unfit for stock; the other has a limited supply of very good water.
7074. No effort has been made to go to a greater depth? I should be inclined to think we should strike salt water if we went deeper.
Site. Boring.
7075. If you desire to strike other wells, have you any means of fixing upon a site where fresh water could be obtained? I have a Tiffin boring-machine, and I put a bore down 493 feet. I struck water at 22 feet from the surface, with a supply of about 3,000 gallons a day; it is good enough for stock, but unfit for domestic purposes.
7076. And have you discontinued that work? Yes; I had to discontinue it when the drought commenced, and I have not recommenced it. I intended to go on with it, but now I do not know whether I shall.
Creeks.
7077. What are the principal creeks on your run? The Culgoa and the Barwon.
7078. Then you have no creeks? No.
Warreena Creek.
7079. What do you call the billabong we have been speaking about? The Warreena Billabong or Creek.
Banks.
7080. What is the nature of the soil on the banks—is it fit for cultivation? With irrigation it would grow produce, but not so as to pay for irrigation.
Fodder.
7081. If you had large stores of water on the river frontage in the billabong would you be induced to cultivate fodder for storage purposes? No, I would not.
Mexican grass.
7082. Are you aware that there is a kind of grass growing luxuriantly on the banks of the Darling which is said to produce to the extent of 120 tons to the acre, and is suitable for cattle and horses? Yes; I saw the plant you speak of at Mr. Gibson's.
7083. If that could be produced to the extent of 120 tons per acre, would it not well repay the expense of irrigation? Yes, unquestionably.
7084. And would it not give you an immense store of fodder to tide over an extremely bad season? Yes, if it could be preserved.

Mr. M. Tully. 26 May, 1885.

7085. Can you give us any particular information gained during your experience here in the way of suggestions? No, I have no suggestions to offer.

Floods. 7086. Is much of your run submerged by shallow water? Not much of it. There are places where the water comes out 4 or 5 miles during extreme floods; nine miles is the furthest it comes, but that is only in one place, and in a narrow strip.

Lignum flat. 7087. Do you know approximately the width of country where that water runs? It is 2 or 3 miles in extent; it is a wide lignum flat.

Levée. 7088. Supposing you were to make an embankment or levée to prevent the water from re-entering the river, what would be the depth? Not more than 15 feet.

7089. The deepest parts would be little billabongs? Yes; they only occur here and there.

7090. Taking the mean of the greatest depths and shallows, what would you consider to be the height of a bank necessary to keep the water in the river course? An average of 9 or 10 feet.

Borings. 7091. Have you kept a section of your borings? I have, but I have not got it here.

7092. Would you furnish a description of it as an appendix to your evidence? Yes. *(Appendix Y.)*

7093. You have been a resident on the Murrumbidgee? Yes, for fifteen years.

7094. On what part? On the higher part, in the Narrandera, Hay, and Jerilderie districts.

7095. Do you know a large billabong that runs from about Tubbo Run? Yes.

Gum Creek. 7096. In which direction does it run? Into the Gum Creek. From there it flows into what they call the Box Creek, and it gets into the Yanko somewhere about Conargo.

Dam. 7097. Do you know whether any effort has been made to retain the water in that creek? Only by damming the creek on the station by means of earthen dams. Mr. M'Caughy has made a dam on the Box Creek.

7098. And these dams, I suppose, are sufficient to store water for a time? Yes; they are only temporary. The creek is shallow in most places.

Storage. 7099. Do you think that overshot dams of a more permanent character would answer the same purpose, and supply water for all time? I think that no overshot dams that could be erected would make it permanent —the creek wants deepening.

Improvements on creeks. 7100. Do you think the creeks generally in that district could be improved after careful examination, by straightening and deepening, and levelling of bars? Yes, I think so.

7101. But that, generally, permanent water cannot be retained except by a system of damming? No.

7102. Do you know if along that creek there are any natural depressions of considerable depth that might be found for storing excess flood-water? I do not know the creek sufficiently well to give a decided answer.

Natural depressions. 7103. *Mr. Barton.*] Do you know of any natural depressions, or dry lakes, or anything of that kind on this run where water could be led by canals or anything of that sort so as to store large quantities of water? I do not know of any where the bottoms are so porous that they would not hold water.

7104. Do you know of any large billabongs except the Warraweena? No.

Springs. 7105. Do you know anything of the Nellie Spring? No; I have been to Thully's mud springs.

7106. How far are they back from the river? About 18 miles from the Culgoa.

7107. And from the Barwon? The nearest point would be over 20 miles.

7108. Do you know of any other springs? Not from personal knowledge. I know from hearsay that there are other springs.

Supply. 7109. Is there any supply of water at this spring? Only a limited supply. Wells have been sunk in the neighbourhood of the spring, within 100 yards from which good fresh water has been got at a depth of from 40 to 70 feet. They had three wells there which, during the drought, watered about 200 head of stock—cattle and horses.

7110. Do you think that the water that supplies these wells is the same that rises in the spring? No, it is different altogether.

Mr. D. W. F. Hatten called in and examined:—

Mr. D. W. F. Hatten. 26 May, 1885.

7111. *Chairman.*] You are the owner of Yanda Station? Yes.

7112. How many years have you been a resident in this district? Eleven years, but I have been twenty-nine years on the Darling.

Yanda Station. 7113. You are well acquainted with the features of the surrounding country for a considerable distance beyond your station? Yes.

7114. I suppose that your general supply of water at the station is some portion of the river frontage? Yes.

Supply. 7115. And on the back blocks water is obtained by means of tanks and wells? Yes; we have one well.

7116. How far, and in what direction, is your station from Bourke? It is 20 miles from Bourke, on the southern side of the river.

7117. How far does it run back? 37½ miles.

7118. Your back country southward then would be in the direction of Cobar? Yes.

7119. Does the country rise towards the back of your station and towards Cobar? Yes; the fall is towards the river from Cobar.

Yanda Creek. 7120. Are there any well-defined creeks or watercourses from the direction of Cobar flowing towards the Darling through your run? Yes; there is Yanda Creek.

Source. 7121. What is the source of that creek? It rises near Cobar, east of it.

7122. What distance would Cobar be from the river? About 80 miles, I think, in a straight line.

Length. 7123. That would be about the length of the creek? Yes.

Width. 7124. At a distance of 20 miles back from the river what is the sectional area of the creek? It varies a good deal; I should think about from 50 to 100 yards in width; that would give a mean width of 75 yards.

Depth. 7125. And what would be the depth? In some places 20 feet, in others 30; I should think an average of 20 feet.

Watershed. 7126. Is the watershed of the creek very wide? Not very wide.

Supply. 7127. The supply depends mainly on the rainfall? Yes; the average waters from the river only back up 5 miles.

Dams. 7128. What is the state of the creek now, after this long dry weather? All the water runs out; the only water in it is held by dams.

7129. You have formed a dam in the creek? Yes.

Site. 7130. Where is it situated? About 20 miles from the river.

7131. What is the nature of the dam? There is a reef of rock crossing the creek at the side of the dam, but we found the drift sand running 19 feet in one of the banks, and we had to go 19 feet to get a solid clay bottom; we found this sand in various layers, and the drift of water-worn gravel extends down for 19 feet. Mr. D. W. F. Hatten. 26 May, 1885.

7132. Did you trench out that depth of 19 feet? Yes.

7133. What did you do? We dug out a trench 18 feet wide and filled that in with surface clay—good sound clay—and worked it with horses and drays, which were constantly carting over it. Trench.

7134. To what height above the creek level did you carry that core of clay? 6 feet. Core of clay.

7135. And you found sufficient cohesiveness in the clay, with the assistance of water, by simply compressing it with the horses and carts? Yes.

7136. You then connected that clay core with the ridge of rocks? Yes; it is a kind of slate formation. Slate formation.

7137. Then you formed your dam over that clay core and ridge of slaty rock? Yes.

7138. To what height did you carry your dam? In the highest part about 24 feet. Height of dam.

7139. What was the width of the dam on top? About 12 feet. Width.

7140. What was the batter of the inner slope? From 3 to 1. Batter.

7141. What was the batter of the slope down stream? About the same; we made it the same on both sides.

7142. What was the result of that? The first flood we have had since was three years after; it came down in January last, the water came down with great force and flooded over the by-wash. There was a low bank at one side, a little above the dam, which acted as a by-wash, and the water followed over there to a width of nearly 100 yards, and fell some little distance from the dam into the creek again, so that the dam was not flanked by the pressure; the dam has held 3 miles of water. Result.

7143. With a 20 feet rise? Yes; that water is standing now.

7144. Have you fixed a gauge so as to know what the evaporation and other loss is? No; the water has gone down 5 feet I should think since it was full. Evaporation.

7145. That is a foot per month? Yes; but during the last six weeks it has gone down scarcely anything.

7146. Then you believe that the great loss at the higher level is due to the permeable nature of the surface soil? Yes; there are great drifts of gravel. Soakage.

7147. After impounding these 3 miles of water behind your dam, what proportion of the water from that rainfall would pass the dam and enter the river? Millions of tons; it was running for sixteen days, and for five days the water did not recede very much; there was a stream of from 50 to 100 yards in width for five days, after which it began to recede. There was an average depth of 2 or 3 feet, and a width of 100 yards. Water entering the river.

7148. What was the extent of the local rainfall which produced that discharge? The rainfall we had was only some 4½ inches, but the fall at the source of the creek was 8 or 9 inches. Rainfall.

7149. For what time? About twenty-four hours, I think.

7150. Do you think that the waste water flowing through the creek was equal to eight times the quantity required to fill a succession of overshot dams throughout the length of the creek? Yes. Waste water.

7151. Then I understand that this creek can only be charged by an occasional excessive rainfall? Yes; there have been several other dams in the creek, but they were carried away by this flood. Rainfall.

7152. What would be the maximum amount of rainfall in twenty-four hours that would ensure a run through the creek from its source to its outlet? That question is very difficult to answer.

7153. Can you suggest any means by which we could get a permanent supply of water in the creek? By making dams every 10 miles. Permanent supply.

7154. But if we make these dams, you say that the rainfall is not reliable? No, it is not; but there are frequent thunder-storms which would flood 10 miles of the creek. I have seen that often, but I have never seen the water run through before.

7155. But if such thunder-storms were localized at the head of the creek, they would only fill high dams such as yours at the head of the creek at the expense of those lower down? Yes; a thunder-storm would benefit the dam which it fell on, but it would not injure any one below.

7156. You are quite satisfied that it is not practicable to carry the Darling water to Cobar? I am quite satisfied of it. Diversion from the Darling.

7157. Do you know anything of the Mulga Creek? Yes. Mulga Creek.

7158. Is it similar to the Yanda? Yes, but not so well defined.

7159. But as a matter of fact it runs through the same country? Yes.

7160. Do you know how the country lies west of Cobar? No; it is undulating—that is all I know.

7161. Have you found the country about your run pretty good for the construction of tanks? Yes; we have sunk thirty-two, and I suppose we have taken out something like 340,000 yards of earth. Tanks. Capacity.

7162. What is the extent of your run in square miles? It is 278,000 acres. Area of run.

7163. What would be the cost of making permanent water for stock on 100 square miles of back country? I should think it would require £4,000 at the lowest calculation to make it permanent; 10,000-yard tanks are of very little use for permanent supply. Cost of water supply.

7164. Then, in consideration of that great expenditure on water for stock, do you not think it would be a great advantage to the whole country if the conservation of flood-waters were carried out under a proper system? Yes, I do. Flood-water conservation.

7165. And if distributed for stock and agricultural purposes it would be an advantage to the whole country? Yes, it would.

7166. And there would be no objection to pay a fair rate equal to the interest on the money expended for the benefits derived from it? No, I do not think that any squatter would object to it. Water-rate.

7167. And how do you think such works ought to be supervised—by local Boards or by a Department in Sydney? I think by local Boards. Local Boards.

7168. Such Boards to have the supervision and maintenance of these works for distribution? Yes, as in the stock districts and sheep districts.

7169. You have a well sunk on the back part of your run? Yes, about 35 miles from the river. Well.

7170. What are the dimensions of the well? 6 × 4 feet. Size.

7171. To what depth was that well sunk? 110 feet. It is in a very low basin, which has the appearance of being an old creek. Depth.

7172. It is an ordinary slab well? Yes.

7173. At what depth did you reach water? We reached fresh water at 37 feet, but there was no supply; the water was found in a very coarse kind of gravel and water-worn pebbles. We put in drives for 20 feet Depth to water.

Mr. D. W. F. Hatton. 26 May, 1885.

on two sides through this gravel and on to the rock, but the supply never increased—the water only rose to 7 feet.

7174. Did you determine in which way the water was flowing when you put in the drives? No; it seemed to be just water percolating through the strata.

7175. And then you proceeded to a greater depth? Yes; at 97 feet we struck very salt water in a kind of rotten rock with iron veins running through it, in some places very hard, in others very soft; there were little cavities in the rock. We then went down 13 feet further, but the water increased so rapidly that we could not keep it baled out with a horse drawing, and we had to give up the work. The water rose to the level of the fresh water—to a height of about 80 feet—and it stands at that; there is 80 feet of water in the well.

7176. You failed to lower the water by any system of baling you could adopt? Yes.

7177. Would a supply of water in that position be of any value to you? Yes.

Condensing water.

7178. It never occurred to you to condense the water? No.

7179. Do you think, considering the value of the water, that you would be justified in attempting to condense it for stock purposes? Yes; only that we do not want it, having so much surface water stored.

Depressions.

7180. Do you know whether, in the vicinity of these creeks, there are any natural depressions which could be connected with the flood levels in the creeks, and be taken advantage of in times of excessive floods? No, I do not think there are.

Legislation.

7181. Can you suggest any means of legislation which would bring about a system of water storage throughout the country which would be beneficial in times of extreme drought? Only by making dams. I think that the Government should take in hand the making of these dams and charge the lessees for the water.

7182. Can you suggest any sort of line by which a calculation could be made as to the quantity of water which might be estimated as required for every block of 10 miles square? No, I could not.

Suggestions.

7183. Can you offer any suggestions which would be useful to us about matters upon which we have not questioned you—do you know of any features of the country which might be dealt with in order to extend the direction of the present line of creeks or direct their courses? No; the Yanda Creek is particularly straight.

Diversion from the Bogan.

7184. *Mr. Barton.*] Do you think from your knowledge of Yanda and Mulga Creeks that it would be possible to turn the Bogan River down them in times of flood, and to fill the dams erected in them so as to make them useful and beneficial to the country? I do not; the country is too high to the south.

7185. Too high between the Bogan and the heads of these creeks? Yes.

Tanks.

7186. Do you think that any better system of tanks could be devised than those now in use, into which stock are allowed to go? I think that it would be better to raise the water into troughs by means of windmills or some means of that kind.

7187. And then less water would supply the same number of stock? Yes, because the stock carry away as much water in their wool as they drink.

Size.

7188. What size of tank would you consider sufficient to hold permanent water to supply the stock that ought to be grazed around it in a fair average season? 10,000 yards if the water was raised, and 20,000 yards if it was not.

Bends.

7189. Do you know of any bends along the Darling where small cuttings across would shorten the river materially, and leave a large holding which might be dammed up to conserve water? Yes, there are bends of 5 or 6 miles in length.

7190. What is the largest one you know of? It is just below Yanda; it is less than half a mile across between the ends of the bend, and it is 4 miles around.

7191. Half a mile of cutting there would save 4 miles in distance, and give you 4 miles for water conservation? Yes.

7192. Do you think, from your knowledge of the ground, that if a small channel were cut there it would wash its way through? I am sure of it.

7193. *Chairman.*] If these 4 miles of river were reserved as a billabong, what would be the sectional area of the river? I should think 500 feet across, and 40 feet deep.

Mr. M. R. Dwyer called in and examined:—

Mr. M. R. Dwyer. 26 May, 1885.

7194. *Chairman.*] You are a pastoral tenant in this part of the country? Yes.

7195. Where is your run situated? It adjoins Mr. Barton's, on Mulga Creek, on the southern side of the Darling.

7196. You have had considerable experience during the period of your residence here? Yes, for about four years; I came here in 1880.

7197. Then your experience has been during the present dry period? Yes, in this part.

Loss of stock.

7198. You had considerable losses of stock during that time? Yes, we lost 9,000 sheep out of 15,000.

7199. What is the extent of your run? 63,500 acres.

7200. And what was the number of your stock? Something like 15,000.

Sheep per acre.

7201. How many acres do you consider should be given to a sheep in this country, safely, under the ordinary conditions of the seasons? During the last drought it would take 20 acres to the sheep. I do not know if that would be sufficient.

7202. You have proved that by their falling off to about that ratio? Yes. If the rain had not come when it did we should have lost them all. Among the 15,000 there were 8,000 young sheep. We first put on 4,000 ewes, and the next year we put on 3,500, and between the two lots they bred up to nearly 15,000.

7203. *Mr. M'Mordie.*] Is not that one sheep to 4 acres? Yes.

7204. Finally the sheep were reduced to one sheep to 8 acres? Yes.

7205. *Chairman.*] Then you found the carrying capacity of your country, at the end of the drought, equal to one sheep to 8 acres? That is about it.

7206. You did not hesitate to put on your run one sheep to 4 acres? No.

7207. But owing to the want of water and grass your stock were reduced by one-half, or one sheep to 8 acres? Yes.

Feed.

7208. And at the end of the time you had no natural feed on your run? No—no grass; the sheep lived on scrub—emu-bush and white bush.

Mr. M. R. Dwyer.
26 May, 1885.

7209. Since then you have had rain, and now have grass? Yes, plenty of grass now.
7210. And you think you have tided over the difficulty with what you have saved? Yes.
7211. What provision have you made for watering the stock? In all I have about 63,000 yards of excavation for storage, but the tanks did not fill; some of them were sunk for three years. Tanks.
7212. At what cost did you make these tanks? We paid 1s. per yard. Cost.
7213. And you think that amount of excavation was absolutely necessary for the number of sheep you had? If the tanks had all been full the country might have carried the sheep, but some of the tanks had been sunk three years before there was sufficient rainfall to fill them.
7214. What did you do during that long interval for watering the stock? I had three tanks full, but two of them were on the side of the road, and the public made use of them and emptied them. Watering stock.
7215. Were those tanks sunk at your expense? Yes. At the time they were sunk there was not such a large amount of traffic as there was afterwards. A tank of 10,000 yards could not supply 3,000 sheep and the quantity of stock that was travelling. Supply from tank.
7216. Had there been a supply of water at the back of your run at that time, from which you could have drawn the water for your stock by gravitation, you would not have hesitated to use the water? No.
7217. And if such a supply had been available at that time, it would have been worth the value of the 9,000 sheep you lost? I do not know that they would all have lived if they had had water, because there was not feed enough—there was not sufficient scrub within reach of the sheep to keep them alive. Cutting scrub is a very great expense; it is better to let the sheep die and buy others. Want of feed.
7218. To prevent a recurrence of such hard times, can you suggest anything that could be done in the way of improving the creeks in the neighbourhood of your run so that they will keep up a supply of water? No; the creeks do not hold. Supply in creeks.
7219. Do you know the Mulga Creek? Yes. The Mulga.
7220. It rises in the watershed towards Cobar, I think? Yes, somewhere near Langtrees, between Cobar and the Bogan.
7221. It has a very large catchment area? Yes, but very little falls into it; in some places the creek nearly runs out level; it loses itself on the flat, and then forms again lower down, and so on throughout its length.
7222. Would it be of general advantage to that part of the country if the creek could be straightened and those shallow parts embanked, so as to retain the water in an artificial channel? I do not think so, for this reason: where this creek passes round you get clay-pans; then you may cross another place where there is a kind of limestone rock like cement, which will take water as fast as a sponge. For instance, I have sunk a tank on my run on the east side of the railway line, and that tank has been filled three times, but it never held—the 2,000 yards would run out in three days. There are several other places like it. Formation.
7223. Do you not know also that there are places not like it intervening between the spots where the soakage takes place? Yes, there are places.
7224. Do you think it would be possible to divert the stream so as to avoid these soakage places? I do not. Diversion.
7225. What would prevent it? There are sandy places that you could not pass, and there is not fall enough on the creek. It is of no use to attempt making dams on that creek; I have one of the largest dams on it, and it is giving way now—the water runs away faster than it could run through a 4-inch pipe. Fall. Dams.
7226. Have you had any experience of wells? I have sunk one, but that was on the other side of the Lachlan. Well.
7227. Not out on the Mulga Creek? No.
7228. You cannot suggest any means which will improve your permanent supply by the storage of storm-waters? No, except by tanks. Storage.
7229. Are there any features of the country which would direct you in constructing a tank so as to enable you to select good retaining country? It is very easy to tell the country that will retain water. There is a great deal of the country upon which you cannot get a place in which to sink a tank. Tanks.
7230. Do you know anything of an inordinate rainfall of 7 or 8 inches at the head of the Yanda and Mulga Creeks? That rainfall did not occur at the head of the Mulga, but from beyond Byerock, nearly as far as my place, and then it went down along the line. If it had kept on another twenty minutes or half an hour it would have gone over the line just past my boundary. Rainfall.
7231. What was the state of the Mulga Creek—was there plenty of water in it then? There was water in the tanks, but none in the dams. Mulga Creek.
7232. What was the state of the Mulga Creek at the time of the heavy rain—was it flowing freely? Yes; it ran eight days past my place, and the dam I had stopped it all. That is the water which is now soaking away. It was at times, I suppose, 20 yards wide, and up to a horse's belly.
7233. *Mr. Barton.*] What do you consider the best kind of tanks for watering stock in this country, both as to size and design? I think about a 10,000-yard tank. Size of tanks.
7234. And do you think it is better to let the stock water in the tank, or to pump it into troughs by means of a windmill or something of that sort? While there is plenty of water in the tank sheep can water at it without doing any harm, but when it gets low it becomes bad, and it is much better in troughs. Stock watering.
7235. Having experienced the late drought, do you think it would be a great benefit to the people if we had cheap lines of railway running through this district, to enable them to get their stock shifted to other pastures? Yes; there would be some chance then of keeping the stock alive. Cheap railways.
7236. If there had been railways available during the last drought, would they have been the means of saving some millions of sheep? I believe they would. Then again, the Sheep Act is very hard against the saving of sheep. Sheep Act.
7237. Do you think the present Act regulating the travelling of sheep requires altering, so as to enable squatters in this part of the country to send their sheep to better pastures in order to save their lives? I think some discretion should be left to the Board so that they might distinguish between bogus sales of sheep and sheep that are being legitimately travelled owing to the want of feed. When a man has not overstocked his country, and wants to travel his sheep to obtain grass or water in times of drought, he should have some consideration.
7238. Then it should be left in the discretion of the local Boards to say whether a man should be allowed to travel his stock by droving; but you do not see any reason why they should have the power to determine where a man should send his stock by rail? No, I do not think they should.
7239. Have you ever felt any inconvenience in this part of the country from stock being allowed to travel by various routes and tracks all leading to the same place? Yes, and so have many others besides me. Stock travelling.

Mr. M. R. Dwyer. 26 May, 1885.

7240. Do you think it a great hardship to squatters that the Government have not defined routes which only they should permit stock to travel? Yes, I do. I think it is a great hardship that people driving stock should be allowed to drive them by either any one of several parallel routes instead of being confined to one principal route.

Mr. Finlay Macrae called in and examined:—

Mr. F. Macrae. 26 May, 1885.

7241. *Chairman.*] Are you a runholder in this district? I am managing for Langloh Parker.

7242. Where is the run situated? On the Hungerford Road, north-west of Bourke.

7243. At what distance from Bourke? About 90 miles.

7244. On what river is the run situated? On no river at all; it runs on part of the Cuttaburra Creek.

Cuttaburra Creek.

7245. The Cuttaburra Creek rises over the border in Queensland, does it not? Yes, I think it runs out of the Warrego in Queensland, and it runs into the Paroo.

7246. Do you know the nature of the country across the border in Queensland? No.

7247. Does the Cuttaburra run through your holding? It runs on to one block of it; it opens out into a large plain on the country we have rented.

7248. How far from Ford's Bridge is the place you are speaking of now? 38 or 40 miles.

7249. Is it called Yantabulla? Yes.

7250. And the Cuttaburra on your station is a well defined creek? No, not on the country we have—it runs out into a large plain; it is a well defined creek from Mogagaroo.

7251. Is not Yantabulla 23 or 24 miles from the border? It is more than that—it must be 40 miles.

7252. Then the last-named place you referred to is to the north of that, and near to the Queensland border? It is to the north-east.

Water supply.

7253. Have you a pretty permanent supply of water in the creek? Yes.

7254. During all the late dry weather? Yes; right through the last drought there was a good supply at Brewarra, but at Mogagaroo it went dry.

7255. Do you know if anything has been done on the Cuttaburra to conserve water? Nothing whatever that I know of. There are no dams now; there may have been some which have washed away.

7256. Have you seen the water running through that creek in large volumes? No, I have not. During the last rain it was not high—not a banker.

7257. Where did the waste water run to? It ran down the plain, and I suppose into Nocoleche Run.

7258. You do not know what fall there is in the bed of the creek, do you? No; I simply know it from riding along.

Distribution.

7259. Then you cannot give us any idea whether it would be worth the trouble to inquire if the water could be carried in an artificial channel through the county of Irrara—whether it could be extended over the flat country by means of a canal? There is sufficient water, I should think, to carry it down; it is a series of clay-pans.

Lake.

7260. Is your main supply for the use of the run obtained on that one creek? No; we have a lake, where most of our sheep are watering now. That lake is situated 25 miles to the south of the creek.

Supply.

7261. Is the lake supplied by drainage from the Cuttaburra Creek? No; from the Kerribee and Coonbillie Creeks.

Sources.

7262. What are the sources of supply of these two creeks? The Kerribee Creek is a tributary of the Irrara, but a great deal of water runs down that creek from local rains.

7263. Do you know if in the centre of the county of Irrara there is a dividing ridge which throws the water into the Warrego and Paroo? I do not.

The Irrara

7264. You know the Irrara Creek, do you not? Yes.

7265. Is it better supplied with water than the Cuttaburra? No, but it is a better creek.

Dams.

7266. Are there many dams on the Irrara Creek? Yes, several; there are three that I know of.

7267. Can you particularize them in their positions? Yes.

7268. Where is the upper one? It is on Robinson's Run, about 25 miles from the Queensland border.

7269. What is the height of that dam? I do not know. It is an earthen dam; it will hold 8 feet of water.

7270. Have you any means of remembering how far that dam backed up the water with an 8-feet rise? I do not know. It all depends on the by-washes. They have secured very much, and when the creek is running they are obliged to be closed.

7271. So that it would not be possible for the water to pass that one dam without destroying the dam itself and the by-washes? No.

7272. So that that dam 25 miles from the border of Queensland would intercept the whole of the water? No; the water runs round.

7273. And in running round it runs over a great amount of flat country? No; it runs into warrambools.

7274. At what distance below that dam is the next dam? 12 miles. It is of similar construction, with natural by-washes.

7275. Where is the one below that again? That is on Goyder's run.

7276. Do you know the particulars of it? No.

7277. You told us that the Cuttaburra Creek was the only one on your run? Yes.

7278. What other means have you of watering stock? We have springs and a well.

Reed springs.

7279. What are the springs? Reed springs they call them.

Peat.

7280. And are those springs depressions on the general surface of the ground? Yes, they are all in a hollow, and the water rises above the surface. The water oozes up through peat, and when it comes through some of the peat comes up, and it runs away down the side then into a gully.

7281. And do you use that gully in the neighbourhood of the spring to water the stock? We have the spring fenced in, with a drain round the fence, and the stock walk round and put their heads in to drink.

Stock.

7282. How is that country stocked? With sheep, horses, and cattle.

7283. How many head of stock can you water? About 4,000 head of sheep.

Supply.

7284. Constantly? Yes; the spring makes very much more water in cold dull weather.

7285. Excepting that, do you know if there is any other cause of a fluctuating supply? I do not.

Wells.

7286. Is there a constant supply? Yes; of course the stock will drink the water down, but it makes again during the night. We have wells sunk through the peat where water is obtained.

Mr. F. Macrae. 26 May, 1885.

7287. How do you sink the wells—with slabbing? Yes. They are only shafts. We get clear water in the wells. I have seen artesian wells put down in exactly the same kind of springs, on Tago and Taree Runs, between the Culgoa and the Warrego.

7288. Who is the owner of that run? Robb & Co.

Artesian wells.

7289. You have seen these artesian wells? Yes; 3-inch pipes were put down—I do not know to what depth, but about 100 yards from the springs—and the result was that the water rose up through the pipes, and troughs conveyed it from the pipes to a tank, into which the water was constantly running. When the tank was full they turned a tap which was on each side of the pipes. They had two pipes down.

7290. How high did the pipes stand above the surface of the ground? 4 feet you might say.

7291. And you have seen the water running? Yes.

7292. Does it run with any force? No force at all—it just trickles out. When the tap is first turned the water runs quickly for a short time.

7293. Do you know whether the pipes have been left to run continuously for any length of time? Yes.

Supply.

7294. What is the longest time they have been allowed to run? They have run until the tanks were full, and I should think there were 5,000 yards in the tank. The tank was filled from the springs, but I do not know whether the water was left running continuously.

7295. Then you do not know really whether the water was running continuously, or whether the spring seemed to be exhausted for a time until the water made again? No, I do not.

7296. Do you know if any extended research has been made to establish the line of that artesian supply? No, I do not. I only know the springs by seeing them, and hearing Mr. Wilson, who put the pipes down, speaking about them.

7297. They appear to have gone just as far as their own requirements demanded? Yes, they watered about 15,000 sheep right through the drought, I am told.

7298. Do you know of any other place where artesian water is to be found? I have not seen any, but I have heard of one at Widgegoara—Mr. Bignell's run.

Size of well.

7299. You speak of a well which has been sunk out in your country—what is the size of that well? It is a 6 feet by 4 feet well.

Depth.

7300. And at what depth in the rock did you find the water? About 13 feet; the water came through the rock.

7301. What is the depth of water on that well? 8 feet; the well is about 27 feet deep.

Strata.

7302. What is the stratum in which the water is found? It is rock; the water comes through the crevices of the rock.

7303. What kind of rock is it—sandstone? No, it is harder than sandstone.

Supply.

7304. And can you maintain a depth of 8 feet in the well? No; you can empty it in half-a-day's drawing, but it will make again in a few hours.

7305. How long will it take to exhaust the well? Five hours, with two large buckets and a windlass—one up and one down the whole time, with three men working at it.

Quality.

7306. What is the nature of the water—is it pure, fresh water? No, not quite fresh, but it is drinkable; the stock are very fond of it.

7307. Do you know of other wells that have been sunk in that district? Wells have been sunk at Yantabulla, but they do not get any supply there; they hardly had water for their own use last December.

Situation.

7308. And how is this well you have been speaking of situated with regard to your station? It is 10 miles to the south of Yantabulla.

7309. It is on the roadside, is it not? Yes, within three-quarters of a mile of the main road to Hungerford.

Other well.

7310. You have no tanks? No. There is another small well which has been put down some years; it is about 1 mile from the well we have now; it has been put down right in a spring on the sand and the water runs over the top, but there is no great supply in it. The well is about 14 feet deep.

Source.

7311. The source of this artesian water has never been discovered? No; it is simply the water rising to its own level.

Depressions.

7312. Do you know if in the county of Irrara, at the outlet of the Cuttaburra Creek, there are any natural depressions which could be used for storage purposes? There are plenty of places where you could make tanks to be filled from the waters of the Cuttaburra.

7313. But as a matter of fact you have not found it necessary to do it? No.

7314. And these creeks, the Irrara and the Cuttaburra, are quite sufficient to supply you with water? There is not sufficient water to supply all the stock that country could carry, but we have not many stock there.

7315. Do you know that at the lower part of the creek, where it joins the Warrego, there is an ana-branch? No; I have not been further than Tinenboro, Mr. Tyson's station.

Mr. Alfred Elliott Randell called in and examined:—

Mr. A. E. Randell. 26 May, 1885.

7316. *Chairman.*] You have been navigating the Darling for a number of years I believe? Yes.

7317. And for the purposes of navigation you are perfectly acquainted with the features of the river, especially the river bed? Yes, decidedly—that is a portion of our business.

7318. And you are also acquainted with the inlets and tributaries and the positions of billabongs of importance? Yes; more so below Wilcannia than at this end of the river.

7319. How many trips have you made between Wilcannia and Bourke? Through trips, only four.

Navigation chart.

7320. This is your navigation chart of the river (*chart produced*) showing all the difficulties and dangers of the river, the positions of rock, and, approximately, the inlets of creeks and outlets of the billabongs? Yes, approximately.

7321. At this time, I believe, your steamer is lying up at Bourke? Yes, owing to insufficiency of water; the river is below what they call the summer level.

Gauge.

7322. Do you know the present gauge that we have in the river? Yes.

7323. At what level does the river stand now on that gauge, above zero? About 5 feet; it is covered with mud.

Navigation level.

7324. How far is the river below navigation level? 4 feet 9 inches.

7325. Then 9 feet 9 inches above zero is your navigation level at Bourke? Yes.

7326. Then a rise of 4 feet 9 inches at the present time would release you from your present position? Yes.

Mr. A. E. Randell. 26 May, 1885.

7327. Do you know if where those rocks are met with in large quantities the stone extends inland? I could not say; they appear to be reefs or ridges of stone running through the country.

7328. But you do not see the stone cropping out of the high banks? No; it is in the bed of the river.

7329. What is the scale of the chart produced? About 4 inches to the mile.

Bends. 7330. There are places on the river where very sharp bends give you large sinuous turnings? Yes.

Cutting. 7331. And by making a straight cut some distance would be saved? Yes, there are places where a mile might be cut off the river by making a straight cut from the bends.

7332. The result of that would be that the flood-waters would cut the channel straight? Yes.

Result. 7333. And what would be the result in the billabong or bend? It would partially silt up to about half the height of the ordinary level of the banks.

Silt. 7334. What would be the nature of the silt? Clay; it would be the mud which is held in suspension in the flood-water.

7335. And when that settles in these disused bends does it make them perfectly watertight. Yes; it is that which forms our lagoons.

Island. 7336. At 13 or 14 miles down the river I see there is an island? Yes.

Creek. 7337. And a creek just up above that island: do you know the name of it? No; we have no names for them—we just put them on the chart, and that is sufficient for us.

Bends. 7338. In a case where two sharp bends of the river are a mile apart, 5 miles of the river might be saved sometimes by making a direct cut? Yes; in many cases you might do that by means of canals.

7339. That would improve the navigation? Yes, but it would let the river away faster.

Lagoon. 7340. And all the disused part of the river would have a tendency to fill up? It would fill up at either end and remain a long lagoon.

Width. 7341. What is the width from bank to bank on top? 80 or 100 yards.

Depth. 7342. By what depth? About 80 feet on an average.

Reservoir. 7343. Supposing that disused part were locked off as a reservoir, it would contain a very large quantity of water in flood-time? Yes.

Bends. 7344. Do you know many places of that kind, where you have to make a great deal of mileage for a short distance? There are many such places.

Cuts. 7345. Here is another place, where you run about 2½ miles, and where a cutting of three-quarters of a mile would make a straight course? Yes; there are many sharp bends where you could save a mile.

7346. In this particular case you would shorten the river, improve the navigation, and save about 3 miles, besides avoiding a very dangerous, rocky part of the river? Yes.

Warrego. 7347. Do you know of any other large inlets so far as I have gone? No; the first large inlet is the Warrego; it comes into the river just above Louth; it is the only large one.

7348. Is the course laid down on this chart the course at ordinary navigation level? Yes; when the river is at the 9 feet 9 inches level we have to take that course.

Dangers. 7349. So that there is scarcely a stretch of 5 miles without dangers in the shape of rocks? No.

Current. 7350. I suppose that when the river is at the lowest navigable level there is very little perceptible current? Except in the narrow places, where it rushes through very strongly.

7351. Then you find that in all cases where the water space is confined there is a pretty good current even at this time of the year? Yes, except when the river is very low indeed. The Darling goes very low—almost dry.

Navigation. 7352. Suppose that the flood-waters were regulated at the head, so as not to allow the excess of flood to come down, would there be any danger in shortening the course of the river? It would affect the navigation; I do not think there would be enough water for navigation all the year round.

Fall. 7353. Do you know what the fall is from Bourke to Wilcannia? I do not; I know that it is about 200 or 230 feet from here to Wentworth.

Traffic. 7354. Do you think that if the navigation could be maintained between Wilcannia and Bourke it would be the means of conveying produce, such as wool, from that place to Bourke? Were it possible to maintain regular communication between Wilcannia and here the trade would all go from here to Wilcannia, and Wilcannia would derive all its supplies from Sydney *via* this place.

Locks. 7355. Have you heard any suggestion as to any means besides locks by which the navigation could be kept open? It is the universal opinion on the river that that is the only means. I have not heard of any other except the scheme of fixed bars in the river; and that we do not consider feasible, because the unloading of cargo would more than neutralize any benefit to be derived from it.

Traffic. 7356. Suppose that the means of communication were kept open, what do you think would be the quantity of wool brought? I can only give a very remote approximation; I should think it would be at least 20,000 bales. They would start from Culpaulin, I should think, and cart the wool; because that is only 18 miles from Wilcannia, and the object of the squatters is to find a regular and quick means of getting their wool away.

7357. What are the means adopted at present below Bourke for the conveyance of wool? Only steamers. We anticipate getting wool from stations outside a radius of 40 miles.

7358. But that entirely depends on the navigable state of the river? If the river is not navigable the wool must remain; they cannot cart wool more than 40 miles without great difficulty.

7359. When did you arrive here on your last trip? On the 27th March.

7360. And you are now imprisoned here? Completely.

7361. *Mr. Barton.*] What is the longest time you have known a steamer to be imprisoned on the Darling? Fifteen months.

Rises in river. 7362. *Chairman.*] And do you depend on the periodical rains? Yes. We anticipate a rise in the river in September; if it does not come then we will expect it in the following March.

7363. So you do not attach much importance to being detained for six months on a trip? We do, but we have to put up with it.

Depressions. 7364. Did it never occur to you from your observation that there were depressions in the banks of the river sufficiently large that, if flood-waters were impounded in them, the river might be kept navigable for a considerable time afterwards, by regulating the water down? Not between here and Wilcannia. There are large lakes at Menindie which would have that effect, but none at this end.

7365. If above Bourke and up to the sources of the river there existed such places as you describe at Wilcannia, capable of storing large quantities of water, do you think that the river could be kept navigable

in

Mr. A. E. Randell. 26 May, 1885.

in the way I suggest? I think not; I thing that the supply is not sufficient to keep the river navigable the whole of the year by storage. I judge from the amount of water which now passes down the river.

7366. But with the addition of the water which might be stored in these large bends of the river? No, I do not think so. Of course I have not the means of judging, but my opinion is that sufficient water does not fall or could be retained to render the river navigable in dry seasons, because it dwindles down so fearfully.

7367. Have you considered the great depth of the upper part of the river, and the navigable surface of it? I have; it is a matter we have often discussed on the river amongst ourselves.

Sectional area.

7368. Have you ever considered the proportion of the sectional area of the navigable stream to the extreme sectional area of the flood level? I have.

7369. What is the proportion? I do not say that I have considered the exact area, but we have considered it in relation to whether we could hold it; I should think that 1-20th of the water would be sufficient.

Navigation.

7370. And if 1-20th of the flood discharge could be maintained by any means, you could make the river navigable from Wilcannia to Bourke? Yes, but that would only be a wave passing down; if the stream could be maintained at that level, it would require 1-20th of the area of the full discharge of the river.

7371. That would be desirable if it could be done? Yes, decidedly, it would be very advantageous, but not so much to the boats, because regularity of communication means low freights; but it would be very nice for the residents.

Storage.

7372. *Mr. M'Mordie.*] Making a very large allowance for possible storage, what length of time do you think that storage would supply water to the river up to navigation level? I do not think that you would have been able to fill any very large storage during the last twelve months—not nearly sufficient to keep the river navigable up to the present time—there has not been sufficient rain.

7373. But suppose you had storage equal to the capacity of the river, and turned it into the river in sufficient quantity to keep up the navigation level, how long do you think that the supply would last? It might last about a week perhaps—not more; it would be a small rush down the river.

Weirs.

7374. *Chairman.*] Have you noticed, in passing up the river, whether there are any advantageous sites for the erection of weirs across the river? Oh yes—two or three places on reefs which at present exist.

Stone.

7375. Are there large quantities of stone to be obtained at these reefs? No, you could not obtain stone except by cutting through the reef, and you would have to remove about 30 feet of earth.

7376. You do not know of any place where a bar exists in the river with a stony ridge near? No; we have very little knowledge of the country back from the river.

Positions.

7377. Can you particularize what you consider the best position for one of these weirs, whether of masonry or any other material? I could particularize several places where there is a reef; the Kennedy reef is one.

7378. Where is that situated? About 50 miles by water above Wilcannia, and 30 miles by land.

7379. Is that below Louth? Yes, it would be about 80 miles below Louth; Mount Murchison Station is the nearest.

7380. If it is near to Mount Murchison Station, then it is not near Wilcannia? It is 50 or 60 miles by water above Wilcannia.

Stone.

7381. What is the nature of the stone? It is very dark, hard stone.

Bar.

7382. Is it a broad bar? Yes, it slopes down; at present there would be a fall of about 3 feet over it.

7383. Then in ordinary navigation levels you can cross that bar? Yes, but it is a great obstacle between Wilcannia and Louth, because there is no channel.

7384. It raises the water about 3 feet above the ordinary level at the present time? Yes.

Erosion.

7385. Do you notice any effects of scouring or erosion of the banks on the side of the river? No, because the reef slopes towards the centre.

7386. And do you think that if that reef were levéed—if the course were carried higher—that that would prevent erosion? Yes; I have seen instances of falls in that way, and I have never noticed any erosion of the banks.

Silt.

7387. Have you ever noticed whether there was much silting on the up-stream side of the bar? No; it deepens away again.

Back-water.

7388. How far back in the river does that bar affect the water? I do not know; the water gets very bad for miles back; I should think it affects it for 10 or 12 miles.

7389. So that by increasing the height you could go still further back? Yes.

7390. And it is only a question with regard to navigation whether any sort of lock could be inserted in that reef? Yes.

7391. You do not know the nature of the rock? I do not; all I know is that it is very hard, and of a granular nature.

River course.

7392. Have you noticed very great changes in the course of the river? In two or three places only.

7393. Can you give any reason for those changes? Yes; the water breaking through narrow necks.

7394. Just as we have been considering? Yes; it breaks through naturally and then silts up.

7395. And the old bends are left as billabongs? Yes.

Soil.

7396. Are you acquainted with the soil in those places? It is all hard clay.

7397. The surface soil is not clay, is it? Yes; I am thinking particularly of a place near Wentworth. In 1877 the river was in its natural bed, but since then it has silted up and made a new course, leaving the old bed as a billabong.

Old course.

7398. Could this old course be shut off at a moderate outlay? Yes; the great difficulty would be to put a strong enough weir at the lower end of the old channel; it is the upper end that always silts first.

Locks.

7399. Can you suggest any practicable means for making the river navigable up to Bourke? What I consider the most practicable plan is to lock the river at the islands in it, because there are natural weirs there already.

Steamer.

7400. Yours is a stern-wheel steamer called the "Corowa"? Yes.

Width.

7401. What is the width of it over-all? About 28 feet; the barges are about 20 feet.

Length.

7402. What is the length of the steamer outside of the wheel, clear of everything? About 120 feet.

7403. Is the barge about the same? The longest barge on the river is about 118 feet.

7404. Then steamer and barge together would make 238 feet over-all? Yes.

Draught.

7405. What is the light draught? About 3 feet.

7406. What is the full cargo draught? It varies; about 4 feet 9 inches to 5 feet with a full load.

Mr. A. E. Randell. 26 May, 1885.

7407. Then in the construction of locks you have considered that both steamer and barge should be locked at the same time? Yes—to save waste of water. For instance, here is a bend of the river about a mile in extent; it is navigable at the lowest level at present, it having a narrow entrance; I would place a lockgate at the upper end, and another at the lower.

Lock-gates.

7408. Do you mean to say that you would place the gates so far apart as to leave only a length of 240 feet between them? If it were artificial entirely I think that it would be sufficient, but by taking advantage of the natural places you could make them half a mile long without any greater expenditure.

Water saving.

7409. But the longer the distance you make between the two gaps, the greater would be the waste of water? Of course; but 238 feet would be quite sufficient; you would want a reservoir to save the water.

7410. Then there would not be any saving of water by taking the steamer and the barge through at the same time? No.

7411. The information you have given to us has been with reference to that portion of the river between Wilcannia and Bourke? Yes.

Talywalkas.

7412. Do you know the position of the entrance to the Talywalka? Yes, to one Talywalka; there are several creeks about Wilcannia called Talywalka.

7413. Did you ever form an approximate idea of the area of the outlet and the depth to which they descend towards the bed of the river? They are the full depth of the river, and on an average are sometimes 1-5th of the width, but they vary of course.

7414. Can you give us any idea of the width of the Talywalkas as they run off? I dare say they are a quarter of the area of the river.

Width. Depth.

7415. What is the width in feet across the top? The average width is about 50 feet at the top, and the depth from 35 to 40 feet.

7416. They are fully charged in times of high floods? Yes, they are all filled up from the river.

7417. And as the river falls, what becomes of the water? It falls into the river again.

7418. Did it ever occur to you that it would be possible to lock the water in these Talywalkas? I have often thought that it could be done, but they narrow very fast as a rule; the greatest depth is at the mouth.

7419. You are aware that although they narrow very rapidly in from the mouth, they convey a very large volume of water into the land beyond? Yes, decidedly.

7420. Do you know many outlets like that to the south-west of the river? There are a number of outlets from the river on the north-west side.

Chart.

7421. Will you give a copy of your chart to the Commission, if it can be traced in Bourke during the time of your detention? Yes, with pleasure; it is a chart made from actual observation, by Messrs. Ebenezer and William Randell.

Mr. G. C. Tompson, Chairman of the Land Board, Bourke District, called in and examined:—

Mr. G. C. Tompson. 26 May, 1885.

7422. *Chairman.*] You have had a long experience of the western portion of this Colony, and you are prepared with notes of your experience? Yes.

7423. Will you kindly read those notes?

I have been a continuous resident in this north-western portion of the Colony upwards of ten years; when I came to the district, in the year 1875, all the back runs were, in the southern portion of the Warrego District, with the exception of Wittagoona, where there were a few cattle and sheep, unstocked, and the only residences in that part of the district were at Wittagoona, 46 miles south-east from the Darling River and on the road from Bourke to Cobar; at Currawcena public-house, 43 miles south from Bourke; at Tindayrey, Campbell's public-house and Mr. Woodhouse's camp, 67 miles from Bourke; the town of Cobar, which had at that time a population under 300, and at Mr. Thomas Lean's selections at Bulgo Spring, 40 miles south from Cobar; on the road from Bourke to Cobar, the Cobar Copper Company, to enable their teams to get to Bourke, which at that time was their only depôt, excavated five small supply tanks, viz.—at Two-waterholes, 15 miles from Bourke; Corrilla, 27 miles; Curraweena, 43 miles; Tindayrey, 67 miles; Mopone, 92 miles. These were very shallow, and consequently ran dry nearly every summer. At Cobar the excavated tanks were very limited, and used frequently in the summer months to run dry. On the road from Cobar to Louth water could be obtained at Wittagoona, which was a natural basin at the foot of a waterfall at head of Wittagoona Creek, and at Keirangundah, where there was a natural waterhole which held water for about three months after rain; this waterhole is on Keirangundah Creek, same creek which runs from Wittagoona and finds its way into the Darling River, on Winbar Run. Mr. Thomas Lean, at his selections at Bulgo, had several shallow wells sunk in the flats between two ranges running into Sandy Creek, and on the banks of Sandy Creek, where he obtained a fair supply from soakage water sufficient for about 3,000 sheep. At Tindayrey Campbell discovered fire-clay, which he sold to the Cobar Copper Company for brickmaking purposes, and thereby by taking out the clay enabled him to make a very deep excavation, which he afterwards converted into a tank for conserving storm-water, and was the means of securing to that part of the district a permanent supply of water for travellers, but not stock. At Bye, which is about 50 miles south-east from Bourke, a shaft was sunk for prospecting for gold; this shaft when I saw it, in May, 1875, had water at a depth of about 20 feet from the surface, but the water was unfit for use in consequence of a large number of dead animals being in it, and the only place water could be procured was at Byerock, 2 miles north from above-mentioned shaft, in a hole in the rock, and this was the only place water could be obtained between Tindayrey and Gongolgon, a distance of about 80 miles. Water could also nearly always be obtained in small spring at south end of Gundabroha Mountains. During the winter of every year from 1875 to 1880 I explored this back country, and have examined every hill and every run in this district. The soil in the back country consists of red chocolate colour, and prior to being stocked was of a very porous nature, and when riding over it the horses would sink in over their fetlocks, except along the Brumby (Wild-horse) tracks, which I always found very useful in discovering shallow pools of water in Yarran Flats for camping purposes; the water was of a reddish brown colour, but could always be made perfectly clear by the use of alum or gypsum. The wild horses and cattle used this back country after rain, and when the gilgais dried up they were compelled to return to the frontages again. The back country is chiefly undulating, and the wild horses and cattle proved very useful, as they formed pads which acted as drains to the gilgais, which soon filled after rain. This country in wet weather was so rotten that if the wild horses went off the tracks they bogged at once, and I have seen them run for miles in Indian file and could not get off the pad (beaten track). In consequence of the porous nature of the soil it was thought impossible to get catches for making tanks, and consequently these blocks at that time were thought so little of that in the year 1874, when £20 per annum rent was put on them, the lessees forfeited them, as they did not consider they were worth that rent. In 1874 two good back blocks changed hands for £45; in 1875 they brought £75. In the winter of 1876, this back country was looking beautifully green with grass and herbage, and the inner districts were suffering from drought; sheep travelling for grass were brought out into this back country, and the persons in charge were granted permission by the late Mr. D. J. O'Neil, who held a large number of these runs, to remain on the country without paying any rent; there was sufficient water in the gilgais by excavating a small tank and drawing the water from the surface into them to last the men from two to three months, and the sheep, with the green herbage, lived during that time without water. All being shepherded proved a great benefit, as the country where the sheep were yarded, after the first rain became quite hard, and acted as a watershed. These sheep were taken back within four months fat, which at once brought the Cobar country into note, and then persons were eager to buy, and blocks changed hands at £300, £500, £800, £1,000, and up to £5,000, and one naked block

block I knew in 1880 to bring £10,000; this block was no better than the two that changed hands in 1875 for £75. The new purchasers in 1876 commenced excavating tanks and fencing-in paddocks, but they experienced great difficulty, the winter seasons of 1877 and 1878 being very dry, and the water in the small gilgais did not last long for men and horses, and many persons had to cart water distances of 20 miles for the men excavating supply tanks, and those that had excavated large tanks had to wait twelve and fifteen months before they got a drop of water in them. 1879 was a magnificent season, and all the tanks in that district were filled with water; the tanks in the first instance only being about 12 feet deep, soon dried up in the summer months; a depth of 18 feet was then adopted, which, except in extraordinary dry seasons were permanent. These blocks were so much improved by the conservation of water that one of the blocks which was forfeited in 1874 because £20 per annum rent was put on it, seven years later changed hands, stocked and improved, at £32,000 cash. This country which, ten years ago, was looked upon as a barren waste on account of having no permanent water upon it, is now by artificial means rendered capable of permanently carrying over a million sheep. Mr. G. C. Tompson. 26 May, 1885.

In this back country there are two long and well defined creeks: first, Mulga Creek, which heads in the county of Flinders, passes through Canbellego and Cowper, and runs into the Darling on Junction Run; the other is Yanda Creek, which heads in the county of Mouramba from the Nyngen Ranges, and runs through the counties of Robinson, Yanda, and Cowper into the Darling River on Yanda Run. Mulga and Yanda Creeks.

The Sandy Creek, which heads in the county of Mouramba, runs into the Darling River; several good places in the creek where water can be obtained by sinking; on Bye Run, county of Cowper, a deep well was sunk, where I understand good stock water was obtained, also good water was obtained in a well at the north-west corner of Glenariff Block H Run; a well was put down on Yanda Creek on Mogenlamba South No. 1 Run over 100 feet—no water obtained; a well was put down at back of Back Dunlop Range at Mulga, where salt water was obtained; in a well known as Taylor's Well on the southern side of Mount Derma good brackish water was obtained, which is used by stock; on Winbar Run another well was put down, known as Cooney Well, where a very fair supply of water was obtained. Sandy Creek. Wells.

There is a small spring on Rankin's Hill No. 3 block B, which in 1877 kept seven horses and three men, but latterly, I am informed, it is not so good.

There is a good creek known as Gidgegelambo, which heads on Rankin's Hill No. 3 block D Run, at Gidgegelambo. There was a magnificent water-hole which I, many years ago, reserved. This creek, I am informed, runs into the Darling River. Gidgegelambo Creek.

A deep well was sunk on the boundary dividing Glenariff block G and H Runs, where salt water was obtained, and afterwards stock water was struck. Well.

These blocks in former years were frequently forfeited when they only had £10 rent on them.

In the northern portion of the Warrego District, on the Irrara Creek, there was one very large earthen dam at Wapwella, which was the means of conserving a large body of water in that creek, which, without artificial means, was a dry watercourse in summer-time. Dam.

In the Warrego River, which has a very narrow and shallow channel, eleven earthen dams were erected between the Queensland boundary and the Darling River, which were the means of conserving large quantities of water, and had it not been for those dams the whole of the Warrego would have been dry. This river is so narrow in places that when it runs it is not more than 2 yards across, and the banks in places being only about 1 foot high, the flood-waters soon leave the channel and inundate the low frontages. Dams in the Warrego.

The Warrego in Queensland, when there is a high flood, overflows its banks, and sends the water across North Darling Back Runs Nos. 10 and 15, which are situate between the north and Culgoa, and I have seen quite creeks running through those runs, and there was a cart bogged which must have been left there many years ago by some drover, showing that they were forced out by the floods. South of those blocks was Colless Spring, which yields a very fair supply of water. East of No. 15 were Gerara Spring, Shearer's Spring, 2 miles north of former, which was an exceedingly good one, and yielded enough water for 7,000 sheep. On North Darling Back Run No. 18 there are three good springs; at Tully's Spring it is a mud one. There is also a very good spring at Leila Woolshed, on East Warrego No. 16 Run. Warrego floods. Springs.

The Culgoa River has some good holes in it which are the means of giving a fair supply of water. The river, when I knew it, had no dams whatever on it, except one in an ana-branch on block B Run, which conserved a fair supply of water. The residents used to put tail dams on the channel just as it was about stopping to run, and thereby gave themselves a fair supply of water. The Culgoa.

The next river, the Bree, was a very small and shallow channel. On this one large dam was made on Milroy, which threw the water back many miles. The end of this dam on the left bank was always being washed away, and it was a heavy expense in keeping it in repair. Higher up this stream tail dams were made when it had nearly stopped running. The Bree.

The Bokhara River, which comes from the Bree River, is not so good, as the water in the Bree has to rise to a certain height to run through Bokhara, and I have on several occasions seen the Bree running and no water in the Bokhara except where it was conserved by means of dams. In the Bokhara there were more dams than on any of the rivers. On the Upper Bokhara, above its junction with the Bree, on Currawillonghi Station, in this Colony, there were two overshot dams which proved a great success, being quite sufficient for conserving a large body of water without wasting any by throwing it over the banks. On the Bokhara, below the Bree junction, there were more permanent earthen dams than on any other river except the Warrego, having no less than nine dams on it, and three overshots. The earthen dams proved a great source of annoyance to the neighbours below each of them, more especially one, as it blocked the water and then diverted out of the channel and irrigated a large area of country before any water found its way back into the channel. In the Narran there were some very good water-holes, and gate dams were used for many years, until the late Mr. Newcomen put an overshot on the river below Angledool, which proved a success for a time until it was partly washed away, and on the Lower Narran there were two earthen dams. This river filled what is known as Narran Lake, and when full is like the sea, as it is treeless and one cannot see across it. The Bokhara. Overshot dams. Narran Lake.

There are wells with good supplies of water on the following runs between the Barwon and Narran Rivers:—Burrawondool; Boorara; Pinegobla; Bukulla; Muggaric Back B; Llanillo; Gorrway; Dungalear Back No. 3; Plumbola Blocks; Combuddery Back. Wells.

There is a large warrambool which crosses the Queensland boundary midway between the Moonie and Narran Rivers, and runs parallel with those rivers some distance and into the Barwon at top boundary of Boorooma.

Another warrambool comes out of the Barwon at top boundary of Dungalear Run, then runs parallel to and distant from the Barwon about 4 miles, and turns into that river at top boundary of Utah Run. I have seen both these warrambools running in flood-times, and experienced very great difficulty in getting through them on horseback, the one nearest the river being a swim. Warrambools.

In the Mara Creek, which runs between the Bogan and Macquarie, there are a great number of earthen and overshot dams which conserve a large body of water. Mara Creek.

WEDNESDAY, 27 MAY, 1885.

At Bourke.

Present:—

Mr. BARTON, M.P.,	Mr. LYNE, M.P.,
Mr. FRANKLIN, C.E.,	Mr. MURRAY, M.P.,
Mr. GIPPS, C.E.,	Mr. M'MORDIE, M.I.C.E.,

Mr. TARGETT, M.P.

W. J. LYNE, Esq., M.P., President, in the Chair.

Mr. G. C. Tompson recalled and further examined:—

7424. *President.*] To which part of the country does the paper you have read refer? To the southern portion of the Warrego district—south of the Darling. Mr. G. C. Tompson. 27 May, 1885.

7425. Have you ever considered the question of diverting a portion of the Macquarie and Bogan waters through the country between Cobar and the Lachlan? Never.

Mr. G. C. Tompson. 27 May, 1885.

7426. Do you know the country from Cobar towards the Lachlan by Nymagee? I know the country from the Bogan across through the Nymagee country, and from there right away out as far as Mount Hope.

7427. What is the nature of the country? After leaving Bourke the soil, until you are approaching Nymagee, is of a chocolate colour, after which you come upon a mixed sandy soil of a lighter description.

Country. 7428. Is it level or undulating? It is undulating country. There are a few isolated mountains, and near Nymagee there is a range of hills.

Range. 7429. About what height? I should think about 200 or 300 feet high.

7430. Is that country generally known as dry country? Yes, but there is a great deal of artificial water.

7431. Is there any permanent artificial water? There is plenty of permanent artificial water.

Tanks. 7432. What do you call permanent artificial water? Water in tanks from 18 to 20 feet deep.

7433. How long would a tank 20 feet deep last without being replenished, supposing that no stock were watered at it? I should not like to answer that question.

7434. Have you no idea? No idea at all. I believe that such a tank would not become dry for two years, provided no stock went to it.

Supply. 7435. How many stock would a 10,000-yard tank, 20 feet deep, water? About 5,000 sheep.

7436. And how long would it last? A whole twelvemonth.

Diversions from the Bogan. 7437. Do you think the country we are referring to, between Cobar and the Lachlan, is of such a nature that it would be possible to divert water from the Bogan through it by means of a canal? In my opinion you could not divert water through there, because the Cobar country rises. Supposing you started from the Macquarie somewhere about Wellington, in order to get the water on to the Cobar country the canal would have to be a tremendous height coming across by the Bogan, otherwise you would flood all the country down the Lower Bogan and the Macquarie.

7438. But do you not know that between the Bogan and the Lachlan there is high country all through? I know nothing about the country lying between the Bogan and the Lachlan, in the counties of Kennedy, Cunningham, Gordon, and Ashburnham.

7439. But suppose that the country in those counties is high, would it then be possible to divert the water from the Upper Bogan and Macquarie? I do not think it would be possible to take the water across into that country.

Canal. 7440. But supposing the country is high enough between the Bogan and the Lachlan to carry a canal into the Nymagee country, would you then think it practicable? I will say this,—that if the water could be conveyed by means of pipes to a high point——

7441. Or an open canal? You could not take it in an open canal, because the country is too high.

7442. But if the country on the other side is high enough, do you think it possible to carry a canal through it? No; because the country in the counties of Kennedy and Cunningham is hilly country, and you would have to go a tremendous way through those hills to get a canal at all.

Creeks. 7443. Are there any falls? There are creeks running through the country.

7444. Is that the only reason why you think the water could not be diverted? Yes.

Soakage. 7445. Do you think it possible to carry water a long distance through dry country? No, because in summer-time it would all soak into the ground as it went along.
